THE
ELEMENTS
OF
MATERIA MEDICA
AND
THERAPEUTICS.

BY
JONATHAN PEREIRA, M.D., F.R.S. & L.S.

THIRD AMERICAN EDITION,
ENLARGED AND IMPROVED BY THE AUTHOR.
INCLUDING NOTICES OF MOST OF THE MEDICINAL SUBSTANCES IN
USE IN THE CIVILIZED WORLD,
AND FORMING AN
ENCYCLOPÆDIA OF MATERIA MEDICA.

EDITED BY
JOSEPH CARSON, M.D.
PROFESSOR OF MATERIA MEDICA AND PHARMACY IN THE UNIVERSITY OF PENNSYLVANIA;
FELLOW OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA, ETC.

VOL. II.

PHILADELPHIA:
BLANCHARD AND LEA.
1854.
Entered according to the Act of Congress, in the year 1853, by
BLANCHARD AND LEA,
in the Office of the Clerk of the District Court in and for the Eastern District of Pennsylvania.
The appearance of the second volume of this work at a considerable period after the publication of the first, would seem to require some explanation other than has been given by the English editors.

As will be perceived from the Preface to the first volume, the author had undertaken a revision of the work so far as it had been printed in England, with especial reference to the American edition. This was performed with respect to three-fourths of the entire Treatise which had been issued, which therefore may be regarded as a fourth edition by him. The remainder has been printed simultaneously with the English edition, the sheets as they were produced being transmitted to the American publishers. A portion of the latter part had undergone the revision of the author himself, but, in consequence of his lamented decease, the residue has been issued under the auspices of the distinguished editors whose preface is appended. The present edition is therefore presented as the last revised work of Dr. Pereira, and the most complete that he published.

With reference to the additions made by the American editor to this second volume, it may be stated that they pertain to the prominent vegetable productions of this country, and to the directions of the United States Pharmacopoeia, in connection with all the articles contained in the volume which are referred to by it. Throughout the two volumes now completed, the last revision of the U. S. Pharmacopoeia has been referred to, and its directions followed. The illustrations have been materially increased over former editions, and where an opportunity presented of inserting in the American edition more finished representations of plants, it has been done from the abundant resources of the publishers. The additions of the American editor are simply inclosed in brackets [ ], while those of the English editors have Ed. appended to them.

December 1, 1853.
PREFACE OF THE ENGLISH EDITORS.

The Second Part of the Second Volume of the Materia Medica of the late Dr. Pereira now laid before the profession, brings to a completion the third edition of this valuable work. In executing the difficult task of completing that which had been so ably commenced by the lamented author, the editors have endeavoured to act in accordance with his views, as embodied in a large collection of notes and memoranda which were entrusted to them for this purpose. They have, on their own responsibility, made such alterations and additions as the present state of science appeared, in their judgment, to render necessary; and the changes made in the preparations of the London and Dublin Pharmacopoeias since the publication of the previous edition have been duly noticed.

At the time of his decease, the learned author had so far advanced with the present volume as to have completed the description of that important article of the materia medica, Cinchona. The remainder of the volume has passed under the revision of the editors; and it may be proper to state that they have in no case interfered with the views or opinions of the author: but, when circumstances rendered it necessary, they have added, in brackets or in notes, such remarks as appeared to them requisite for the further elucidation of the subject. For some assistance in the performance of this duty, they feel bound to express their obligations to Mr. Jacob Bell and to Mr. Daniel Hanbury. Mr. Bell freely placed at their disposal the numerous papers contributed by the late Dr. Pereira to the pages of the Pharmaceutical Journal.

It will be perceived that the present edition of this standard scientific work has assumed an entirely new shape. The Mineral substances of the materia medica have been confined to the first, and the Organic substances to the second volume. Considerable additions have been made to both departments: but the Organic Materia Medica has been especially enlarged. The additions comprise four hundred pages of new matter; and the articles of materia medica, of which a complete medical and scientific history is given, amount to three hundred and sixty. Of the value of the matter thus contributed to the medical literature of the day the Editors feel themselves at liberty to speak, since the author is now no more, and they have

1 The first part of Volume Second was published in London, before the decease of the author.
merely aided in carrying out his views in one small portion of this elaborate treatise. Their opinion is the expression of the opinion of the whole profession, both in this and foreign countries—namely, that in copiousness of details, in extent, variety, and accuracy of information, and in lucid explanation of difficult and recondite subjects, it surpasses all other works on Materia Medica hitherto published. The history of a drug, as it is given in these volumes, is not a dry description of its physical characters and its medicinal uses. Philology, Natural History, Botany, Chemistry, Physics, and the Microscope, are all brought forward to elucidate the subject; and the reader thus acquires a full scientific knowledge of each article of materia medica before he is introduced to a description of its effects on plants, animals, and man, or to the various theories of its operation, and the different uses to which it has been applied in ancient and modern times. In illustration of this statement, we refer to Article 232, on Cinchona, the last which passed under the hand of the author. This article, when taken alone, displays an amount of scientific knowledge, a degree of industry in the collection of facts, and a judgment in selecting and describing them, which it is rare to meet with in one individual. In treating of the properties of the Cinchona alkaloids, it will be observed that even the abstruse subject of epipolization, or the internal dispersion of light, as a test for quina, has not escaped his notice. It was a peculiar feature in the writings of the author—one which is stamped upon every page of this treatise—that he was not satisfied until he had thoroughly exhausted the subject. His references to ancient and modern writers are constant and numerous; he goes to all sources which are capable of yielding information, and fairly acknowledges his obligations to those by whose learning, experience, or research, he profits. He has thus succeeded in transforming the substance of an unpretending course of lectures into a complete Encyclopaedia of Materia Medica. We entertain no doubt that the present edition will be found to add to that high reputation which, while living, the author had acquired by his researches in this important branch of medical science.

ALFRED SWAINE TAYLOR.
GEORGE OWEN REES.

**LIST OF WOODCUTS IN VOL. II.**
**EXPLANATION OF PLATE I.**

This plate represents the appearance of starch grains when moistened with water, and viewed by a power capable of magnifying 250 diameters. In order that the reader may compare the sizes of the different grains, the micrometer lines are faintly indicated; each of the square spaces between the lines represents the \frac{1}{10000}th part of a square inch.

1. **Wheat Starch.**—Most of the larger particles present their flattened faces to the observer. Three particles, seen edgeways, have a stronger lateral shading. (For a description of the grains, see p. 125.)

2. **Barley Starch.**—As wheat starch. (See p. 115.)

3. **Oat Starch.** (See p. 112.)

4. **Rye Starch.** (See p. 118.)

5. **Maize Starch.**—The upper portion represents isolated grains. The lower portion (a) represents a mass of grains, as seen in the outer or horny portion of the cells, the albumen with the cells in situ. (See p. 110.)

6. **Rice Starch.** (See p. 108.)

7. **Sago Meal.** (See p. 163.)

8. **Starch Grains of Pearl Sago.** (See p. 165.)

9. **Starch Grains of False Sago made from Potato Starch.**—One of the grains has escaped the action of the heating process to which they have been subjected; all the others have been ruptured. Chiefly taken from a specimen of Planche’s “Sagou de la Nouvelle Guinée.” (See pp. 166—7.

**EXPLANATION OF PLATE II.**

10. **West India Arrow-root** (Maranta Arundinacea). (See p. 224.)

11. **Portland Arrow-root** (Arum). (See p. 387.)

12. **East India Arrow-root** (Marantà Indica). (See p. 224.)

13. **Tous Les Mois** (Canna Coccinea). (See p. 227.)

14. **Tapioca** (Janipha Manihot). (See p. 381.)

15. **Do.** (See p. 381.)

16. **Starch of the Cycas Cireinalis.** (See p. 283.)

17. **Potato Starch** (Solanum Tuberosum). (See p. 501.)

18. **Tahiti Arrow-root** (Tacca Oceanica). (See p. 221.)

19. **Starch of the Yam** (Dioscorea Villosa). (See p. 260.)

20. **Starch of the Pea** (Pisum).

21. **Starch of the Plantain** (Musa Paradisiaca). (See p. 223.)

OF

THE HISTORY AND LITERATURE OF THE MATERIA MEDICA.

I. WORKS ON THE HISTORY OF MEDICINE GENERALLY.

Dr. D. Le Clerc. *Histoire de la Médecine*. Gen. 1696. 4to.; à la Haye, 1729. (Brought down to the time of Galen. An Engl. transl, by Drs. Drake and Baden. 8vo. Lond. 1699.)

Dr. J. Bostock. *History of Medicine, in the Cyclopedia of Pract. Med. vol. i.*

Dr. C. Brousais. *Atlas Historique et Bibliographique de la Médecine, ou Histoire de la Médecine*. Paris. 1834. fol. (A translation of Choulant’s Tables, with additions to some of them.)

II. WORKS CONTAINING A SPECIAL HISTORY OF PHARMACOLOGY.

Choulant, op. supra cit.

Dr. C. Brousais. Op. supra cit. (Choulant’s Table in French, without additions.)

EGYPTIAN MEDICINE.

b.c. Trout or Thaut (also called Hermes or Mercury), regarded as the founder of Medicine.

Medicine practised first by priests, afterwards by physicians who confined themselves to the study of one disease. (Herod. *Euterpe lxxxiv.*)

The sick exposed in public places (Strabo).

Purges, vomits, and clysters, used for three days successively in every month. (Ibid. *lxxvii.*) Dietetical regulations: the hog regarded as unclean. Baths and unguents.
**HISTORICAL TABLE OF THE MATERIA MEDICA.**

**B.C.**

Worshipped a bulbous plant ( koşμματα; Squilla?), to which they erected a temple (Pauw).

Employed alāties, slime of the Nile, frictions with crocodiles' fat in rheumatism, and mucilage of semina psyllii. Salt, νίτερ (carbonate of soda?), alum, plasters, and unguents; white lead and verdigris occasionally entered into the latter.

Fumigations with Cyphi (Κυψηλος), a mixture of various drugs. (Dioscorides, i. 24.)

Spices, balm, and myrrh, carried to Egypt. (Gen. xxxvii. 25.)

1729

Embalmings practised. Palm wine, aromatics, myrrh, cassia, and other odorous substances (not frankincense), as well as νίτερ (carb. soda ?) and gum used in this process.

* * * Consult—M. De Pauw, "Phil. Disert. on the Egyptians and Chinese." Vol. i. p. 130. 1795.

Prosper Alpinus, "De Medic. Ägypt." 

---

**HEBREW MEDICINE.**

The infliction and cure of diseases on various occasions ascribed by the Sacred Historian to the direct interposition of God. (Exod. ix. 15. Numb. xii. 10.) Remedial agents consisted principally in strict hygienic means. (Circumcision, dietetical rules, separation, ablation, combustion of infected garments. See Gen. xvii. 10. Lev. xi. and xiii. 2 Kings v.)

1491

Medicine practised by the Priests. (Lev. xiv.) Gold, silver, lead, tin, iron, and brass (copper?) mentioned by Moses.

1491

Odoriferous ointment and confection; the most ancient recipes on record. (Exod. xxx. 23–25, and 34, 35.)

1063

Music employed as a remedy. (Sam. xvi. 16.)

884

Sesquisulphuret of antimony (?) used as a face paint. (2 Kings ix. 30.)

713

Fig poultice. (2 Kings xx. 7.)

600

Physicians (not priests) referred to. (Jerem. viii. 22.) N.B. The so-called Egyptian physicians (Gen. i. 2) were probably ἱσταμενοὶ, undertakers or embalmers.

The following substances are referred to in the Bible: the olive, saffron, barley, wheat, the fig, the vine, myrrh, bdellium, galbanum, cumin, coriander, flax, garlic, balm of Gilead, olibanum (frankincense), cassia, cinnamon, the almond, the pomegranate, dill (in our translation incorrectly called anise), colocynth? ricinus?

40

Herod was let down into a bath of oil. (Josephus, Bell. Jud. lib. i. cap. 33, § 5.) Oil and wine applied to wounds. (Luke x. 34.)

Various superstitious practices. (Adam Clarke, Comm., Note to Mark v. 26.)

---

**ASSYRIANS.**

The Babylonians had no professors of medicine. They exposed their sick in public places, in order that passengers might communicate their experience as to the best mode of cure. (Herodotus, Clío cxvii.) Extracted oil from the Sesamum. (Ibid. cxviii.)

CHINESE MEDICINE.

229

Of its ancient state but little is known. The Chinese pretend that its study was coeval with the foundation of their empire, and that their medical code was the production of Huang-ti, B.C. 2000 (Grosier.) Before the Christian era there was a constant communication between China and India. (Asiat. Journ. July, 1836.)

Medical science commenced with Chang-ka; for all works before that (said to be dated B.C. 1105 and 189) treat of medicine without giving prescriptions. (Trans. of Med. Soc. of Calcutta, p. 146.) As the Chinese have retained their ancient manners and customs, we must judge of what their medicine was by what it is.

Pun-tsao (or Herbal), the most considerable Chinese work on Materia Medica, includes minerals, vegetables, and animals. (Davies, ii. 278.)

Ching che chun ching (Approved marked line of Medical Practice), a celebrated work, in 40 vols.; of which eight are devoted to Luy-fang (Pharmacology). The articles of the Materia Medica are very numerous. Ginseng is their panacea. Aromatics and gums in apoplectic cases. Opium as an anodyne and in dysentery. Mercury both raw and oxidized. Musk, rhubarb, tea, camphor of the Dryobalanops, asafetida, spices, larvae of the silk-worm, bones of tigers and elephants, vegetable wax, horns, fins, &c. Moxa. Croton Tiglium.

* * *

HINDOO MEDICINE.

1. Ancient Medical Authorities and their Works.

Braham, the Hindoo Deity; author of the Vedas, the most ancient books of the Hindoos, and next in antiquity to those of Moses. (Sir W. Jones, Disc. ix.)

Ayur Veda, the oldest medical writing of the Hindoos, forms a part of the 4th or Atharva Veda (the least ancient Veda). It is distributed into eight subdivisions. (See H. H. Wilson, Calcutta Oriental. Mag. Feb. and March, 1823; and Royle, Essay, p. 57.)

Dachsa, the Prajapati, to whom Braham communicated the Ayur Veda, instructed the twoAswina or Sons of Surya (the Surgical attendants of the gods). According to some, the Aswins instructed Indra, the preceptor of Dhanwan-tari (also styled Kastrija, prince of Benares); but others make Atriya, Bhadwaja, and Chahaka, prior to the latter.

Chahaka (Saras, Scarac, Scirak or Xarac) mentioned by Serapion, Avicenna, and Rhazes. His work is extant, but not translated.

Susruta, son of Visvamitra, was pupil of Dhanwan-tari and contemporary of Rama. Treats chiefly of Salya and Salekya or Surgery, and divides medicines into locomotive (animals both viviparous and oviparous, and produced in moist places) and non-locomotive (plants and minerals). Gold, silver, arsenic, mercury, diamonds, earths, and pearls are enumerated; also heat and cold, light and darkness, the increase and decrease of the moon's age, as medicinal means. Lithotomy, the extraction of the fetus, venesection. 127 weapons and instruments. Actual cautery. Alkaline caustics. Heated metallic plates. Leccehes. Gourds used as cupping-glasses. Astringent and emollient applications. Leaves, plasters, threads, and bandages. Drastic and mild purgatives, emetics, diaphoretics, baths, and aspersions of water, stimulants, sedatives, narcotics, and acrid poisons all employed. Datura, nux vomica, croton tiglium, myrobalans, &c., were adopted by the Arabs.

* * *

The Susruta; or System of Med. taught by Dhanwan-tari, and composed by his disciple Susruta. Vol. i. 8vo. Calcutta 1835.

2. Early Translations from Hindoo Works.

a. Tamul, by Maha Rishi Ashaflfer, who is named in the Ramayana, the oldest Hindoo profane work, and which is supposed to have been revised by the poetical Calchas in the reign of Vikramaditya, whose era commences B.C. 57. (For a classification of drugs in a Tamul work called the Kalpastanum, see Royle's Essay, p. 54.)
HISTORICAL TABLE OF THE MATERIA MEDICA.

2. Cingalese. (See a list in Ainslie's *Mat. Ind.* vol. ii. p. 525; also Heyne's *Tracts on India*, pp. 125-171.)

3. Tibetan made in the eighth century. (See Csona de Körös, in *Journ. Asiatic Soc.* iv. 1.) 715 substances are mentioned, most of which are indigenous in India.

Cannot be determined by Hindoo chronology or authors: hence must be ascertained from other sources. The great antiquity of Hindoo medicine is proved by the following circumstances:

a. Indian products are mentioned in the Bible. (Royle, p. 138.) In early times, commerce was established between India and Persia, Syria, and Babylon; also by the Persian and Arabian Gulfs with Egypt, &c.

b. At a very early period, India was peopled and in a high state of civilization. (For proofs, see Royle, pp. 160-179.) As many chemical arts (e. g. distillation, bleaching, dyeing, calico-printing, tanning, soap and glass-making, manufacture of sugar and indigo) were practised by the Hindoos, who were acquainted with, and their country contains all the chemical substances mentioned by Geber, it is not improbable that they and not the Arabs originated chemistry. The Grecian sages travelled in the East: hence the coincidences between the systems and discoveries of the Greeks and those recorded in Sanscrit works.

c. Indian products are mentioned by the Greeks and Romans (e. g. by Hippocrates, Theophrastus, Dioscorides, Pliny, Oribasius, Elius, and Paulus). They were doubtless employed in the countries where they were indigenous before they were exported.

d. Ancient inscriptions show the antiquity of Hindoo medicine. A medical edict by King Pyyadasi, directing the establishment of depôts of medicines, and the planting of medicinal roots and herbs throughout his dominions and in the countries where Antiochus and his generals command. This, therefore, must have been issued, and cut in rocks and metal pillars as early as B.C. 220.

e. The Persians translated Hindoo works A.D. 551 to 579. (Royle's Essay, p. 68.)

f. Hindoo physicians were in high repute at the court of Harum Al-Rashid and Al-Mumoon, from A.D. 786 to 850.

g. The Arabian authors (Rhazes, Serapion, Mesue, and Avicenna) mention Charak, and quote from the Susruta.

* * *

GREEK MEDICINE.

1. Before the time of Hippocrates.

B.C.

1398 Melampus, a soothsayer and physician. Cured impotence by iron wine (Apollod. *Bibl.* Fr. transl. lib. i. cap. ix. p. 75); and madness by hellebore (Pliny, xxv. 21).

1270 Chiron the Centaur, a physician and surgeon. Was cured of a wound by the Centaurea Centaurium (lbid. xxv. 30).

1263 *Æsculapius* or *Asclepias*, renowned for his medical and surgical skill. His sons, *Machaon* and *Podalirius*, also famous surgeons; the latter practised venesection.

1134 The first temple to *Æsculapius* founded.

*Æsclepiades*, descendants of *Æsculapius* and priests of his temples. Votive tablets suspended in the temples.

908 *Euphorion*, author of the *Thyrsus* or Ciudag of Cnidian Sentences.

907 Homer mentions the Papaver somniferum, *mārimicus* (Cannabis indica? opium?), 884 (Moly (?)), &c.

617 *Aristæus* discovered Silphium.

3300-500 *Pythagoras* employed magic, dietetics, mustard, anise, and vinegar of squills (Pliny, xix. 30).
2. Hippocrates.

460—360 B.C. HIPPOCRATES, the "Father of Medicine." Born at Cos. The 18th by his father from Æschylus. Ascribes diseases to alterations of the humours (blood, phlegm, and yellow and black bile. An antipathic. Employed diet, baths, exercise, bloodletting (venesection, cupping, and scarification), the actual cauter, the knife, and a very extensive series of medicines. His Materia Medica includes:

1st. Minerals—sulphur, lime, carbonate of soda, alum, common salt, oxide and carbonate of lead, acetate (and sulphate?) of copper, oxide of iron, and yellow and red sulphuret of arsenicum.

2dly. Vegetables—acacia, allium, ammoniacum, anethum, anisium, cardamomum, cassia, cinnamon, colocoly, conium, coriandrum, coccus, cummin, cydonia, elaterium (?), euphorbia, fenniculum, galbanum, galia, glycyrrhiza, gnidium, helieborus, hyoscyamus, juniper, lactua, laurus, linum, malva, marriium, mastic, mentha, morus, myrrha, olea, opium, opobalsamum, opopanax, origanum, piper, piz, palegium, piumica, quercus, rosa, rubia, rumex, ruta, sambucus, sanguinum, santonina, scilla, siliquum, stetris, staphisagria, styx, turpentine, and veratum.

3dly. Animals—Kabæic (Mylabris Fusselini?); castoreum, sepia, ova, cornea, mel, serum lactis, and cera.

3. From Hippocrates to Galen.

380 ANCIENm DOGMATIC (or Hippocratican) SCHOOL (Theory in Medicine). 380. Founded by THESSALUS and DRACO (sons of Hippocrates), in conjunction with POLYBIUS (their brother-in-law).—354. DILOCRÈS CHÀSYSTÈS (called the second Hippocrates), wrote on plants and dietetics. Gave a leaden bullet in his works.—341. PRAAXAGORAS OF COS (the last of the Asclepiadea); vegetable medicines—336. CRUSTIPPSUS OF CIRDUS, opposed bleeding and purging, and vegetable medicines.

307—304 ALEXANDRIAN SCHOOL.—304. ERASISTRATUS (pupil of Chrysippus) opposed bleeding; used simple medicines.—307. HEROPHILUS OF CHALCEDON, a demi empiric, used compound and specific medicines.—285. Medicine divided into dietetics, pharmacy, and surgery.

384—322 NATURAL HISTORIANS.—384—322. ARISTOTLE; wrote on animals (also on plants and pharmacy).—371—286. THEOPHRASTUS, the founder of Botany.

290 EMPIRIC SECT (experience the sole guide) 290, founded by PHILINUS OF COS (disciple of Herophilus).—240. SERAPION OF ALEXANDRIA.—230. HERACLIDES OF TARENTUM ("Prince of Empirics") used conium, opium, and hyoscyamus, as counter-poisons. NICANDER OF COLOPHON wrote on poisons and antidotes; his GNPÈKÀ and AÎSTOîFÎMÀ still extant.—135 to 63. MITHRIPATES; his supposed antidote (Mithridatium Dakomacis) contained 54 substances.—158. ZOPHERUS employed a general antidote (Ambrosia); classified medicines according to their effects. CRATEVERS, a botanist.—138. CLEOPHANTUS described medical plants.

160 GENTIAN first used by Gentius, king of Illyria.

100 METHODIC SECT.—100. ASCLEPIADES, of Elymania, rejected all previous opinions, and termed the Hippocratic system "a meditation on death."—63. THEMISON, of Laudicea, pupil of Asclepiades, founder of the sect. Explained all physiological and pathological doctrines by the strictum and laxum of the organic pores, and regarded all medicines as astringents or relaxants. Employed leeches.

54. PEDACCIUS DOSCORIDES. The most renowned of all the old writers on Materia Medica. His work is the best (of the ancient ones) on the subject, and for 1600 years was regarded as the first authority. "In him I counted about 90 minerals, 700 plants, and 168 animal substances, that is, 958 in all, without reckoning the different simples the same substance often affords." (Alston, Lect. i. 15.) Dr. Sibthorp visited Greece for the purpose of studying on the spot the Greek plants of Dioscorides. (Flora Graeca; and Prod. Pl. Graec. by Sir J. E. Smith.)

131—200 CLAUDIUS GALEN, a brilliant genius, of vast erudition and rare talents. Explained the operation of medicines by reference to their elementary qualities (heat, cold, dryness, and moisture), of each of which he admitted four degrees. This doctrine was held in the schools until the time of Paracelsus.
4. From Galen to the fall of the Greek School.

(Minor Greek Authors.)

**ROMANS or ITALIANS.**

In the early periods of Roman history, medicine was practised by slaves and freedmen.

13—55  A. Cornelius Celsus. *De Medicina.* A methodist. An elegant writer. Lays down hygienic rules. Distinguishes foods according to the degree of their nutritive power and digestibility. His remarks on these subjects, as well as on the use of remedial agents generally, display great judgment. Speaks of the use of nourishing oysters, gestation, baths, frictions, &c. Employed in dropsy frictions with oil.

41  Scribonius Largus. An empiric. His work (*Compositiones Medicinae*) is the first pharmacopoeia known.

23—79  Caius Pliny the Elder. A natural historian. In his work (*Historia Naturalis*) he has collected all that was known in his time, of the arts, sciences, natural history, &c. He displays prodigious learning and a vast fund of erudition. In Botany and *Materia Medica* he has copied almost verbatim the remarks of Theophrastus and Dioscorides.

230  Celsus Aurelianus. A methodist. The only one of this sect whose works have descended to us.

**PERSIAN MEDICINE.**

1491  Must be very ancient, but its history scarcely known. Products of Persia (ex-gel-banum, assa-fetida, sagapum, &c.) mentioned in the Bible or by Hippocrates: it is to be presumed that the Persians knew the medical qualities of their indigenous drugs, previous to selling them.

400  Ctesias of Cnidus, physician for seventeen years to Artaxerxes Mnemon.

A.D. 272  Deschondisbour (Jondisabur or Nisabur) founded. Greek physicians sent by the Emperor Aurelian.

Almanzor, the second caliph of the house of Abbas, a great encourager of the sciences and medicine.

**ARABIANS.**

The doctrines of Hippocrates and Galen taught. Mild laxatives (as cassia, tamarinda, manna, rhubarb, and senna) substituted for drastics. Chemical medicines mentioned. Various pharmaceutical preparations (syrups, juleps, conserves, looches, robins, and distilled waters and oils) contrived. Dispensatories published.

622  Aaron or Ahron (*The Pandects*).

Died 872  Ibn-Sahel (Sabor) Krabadin, the first dispensatory.

Died 880  J. Alkhende. Wrote on the proportion and doses of medicines.

——
HISTORICAL TABLE OF THE MATERIA MEDICA.

A.D. 1240—1313 ARNOLD OF VILLA NOVA. Wrote a commentary on the Medicina Salernitana prepared the oils of turpentine and rosemary.

1235—1315 RAYMOND LULLY. Prepared the oil of rosemary, acetate of lead, ammonium chloride of mercury, nitric oxide of mercury, and spirit of wine.

1295 SIMON DE CORDO. 1317. MATTHEW SYLVATICUS. 1320. (death) PETER DE

1320 APO. 1328. Francis of PIERMONT. 1343. Donbis, father and son.

1343 JOHN PLATERIUS. Antidotarium Nicolai cum expositione. St. ANDOIN. Red oxide of mercury.

Born 1394 BASIL VALENTINE. Prepared chemical medicines. Introduced antimonials (curris triumphalit antimoni). Was acquainted with the double chloride of iron and ammonium, and the acetates of lead.

1418 VALESCUS DE TARENTA.

1491 ORTS sanitatis (first botanical figures).

1492 COLUMBUS discovers America. Tobacco and its use for smoking first known.

1497 MERCURY employed externally in syphilis.

1506 Guaiacum introduced into Europe by the Spaniards.

1493—1541 PARACELSUS. A vain, ignorant, arrogant, drunken quack, fanatic, and impostor. He burnt publicly the works of Galen and Avicenna, declaring that his shoe-strings possessed more knowledge than those two celebrated physicians, and asserted that he possessed the elixir of life! He was a cabalist, astrologer, and believer in the doctrine of signatures. He conferred several important benefits on medicine; he overturned Galenism, introduced chemical medicines (employing mercury in syphilis), and substituted tinctures, essences, and extracts, for various disguising preparations.

1530 Sarsaparilla first appeared in Europe.

Early botanists in whose works several medicinal plants are distinctly referred to, in some cases for the first time. 1530. BRUNFELSIUS; Cardamine pratensis; Scrophularia nodosa. 1532. THAGUS; Foxglove (Campanula sylvestris); Belladonna (Solanum hortense nigrum), Dulcamara. 1542. FUCSUS; Stramonium; Digitalis.

1579 Winter’s bark brought to Europe.

1633 Serpentine root noticed by THOMAS JOHNSON.

1675 Sulphate of magnesia obtained from Epsom waters by Dr. GREW.

1740 SPIGELIA as an anthelmintic made known.

1742 SENEGA introduced by Dr. TENNANT.

1758 KINO described by Dr. FOATHERGILL.

1763 Bark of salix alba used by Rev. Mr. STONE.

1788 Angostura bark imported into England.

THE BRITISH ISLES.

1. Ancient British Medicine.

(To the end of the 5th century a.d.)

MEDICINE OF THE ANCIENT BRITONS. Medicine and surgery practised by the Druids, who employed charms and certain medicinal agents (for which they entertained a superstitious veneration), and practised the simpler operations of pharmacy.

Their chief medicines were the mistleto of the oak, selago, vervain, and samllus. To the serpent’s egg (anguinum) they ascribed supernatural powers.

(From the end of the 5th to the end of the 15th century a.d.)

ANGLO-SAXON MEDICINE. Medicine and surgery practised by women, and subsequently by ecclesiastics and leeches (medici, chirurgi). They employed a variety of superstitious practices, and ascribed the virtues of drugs to imaginary (planetary, sol-lunar, &c.) influences. Their principal medicines were herbs.

Their chief (MS.) works on medicines which were in use at this period were the following:

1. L. APPULEII, de Herbarum virtutibus Historia. (It pretends to contain the doctrines which Chiron the Centaur taught to Achilles).

2. De Betonica. (This work has been ascribed by some to L. Appuleius, by others to Antonius Musa.)

3. Medicina animalium. (Ascribed to Sextus Philosophus.)
ANGLO-NORMAN AND EARLY ENGLISH MEDICINE. During this period medicine, and especially the Materia Medica, began to be studied as a science. At first the chief teachers and practitioners were ecclesiastical; but gradually the practice of medicine became transferred to laymen, and the distinction between physicians, surgeons, and apothecaries was established. Alchemy was sedulously pursued at this time.

Subsequently to the Crusades (A.D. 1096—1248) spices, gums, and other oriental substances were introduced into medicinal use, and thus the grocers who supplied these became apothecaries. The early grocer-apothecaries to the crown were foreigners. In A.D. 1231, there existed a fraternity of pepperers; in A.D. 1345 the grocers were incorporated; and in A.D. 1456 they fined one John Ayshfielde six shillings and eight pence "for makynge of untenwe powder of gynger, cynamon, and saunders."

GILBERTUS ANGLICUS (by some called Gilbertus Legleus), author of Compendium Medicina. (Prepared a solution of acetate of ammonia and oil of tartar deligium.)

ROGER BACON. (The most philosophical of the alchemists. Described the method of making tinctures and elixirs, and laid down rules for diet and medicines.)

JOHN OF GADDENDEN, author of the Rosa Anglica. (Discovered the method of bleaching wax, of making saccharum pendium, of producing fresh from salt water by repeated percolation through sand, and by distillation, &c. &c. His work abounds in recipes for every complaint; and affords the best history of what medicines were in use in his time; but it is characterized by the ignorance and superstition of the age, and by the grossest quackery.)

(From the end of the 15th century A.D. to the present time.)

ENGLISH MEDICINE. Establishment of the scientific study of medicine. Statutes passed for the regulation of the practice of medicine. Charters granted for the incorporation of the various orders of the profession. Employment of chemical medicines.

Statutes, Charters, &c.

The examination and admission of physicians and surgeons by the bishop of the diocese, aided by members of the faculty, 3 Hen. 8, c. 11.

Incorporation of the Royal College of Physicians of London by charter.

Charter confirmed by statute. Examination and admission to the exercise of physic in England vested in the College, 14 and 15 Hen. 8, c. 5.

Physicians to examine drugs, 32 Hen. 8, c. 40.

Surgeons incorporated with the barbers, 32 Hen. 8, c. 42.

Ministration of medicines for external diseases allowed to every one, 34 and 35 Hen. 8, c. 8.

Wardens of the grocers to go with the physicians to examine "poticary wares, drugs, and compositions," 1 Mar. sess. 2, c. 9.

Apothecaries incorporated with the grocers.

The apothecaries separately incorporated by the name of the "Master, Wardens, and Society of the Art and Mystery of Pharmacopolites of the City of London." Charter, 13 Jan. 1.

The union of barbers and surgeons dissolved, and the surgeons separately incorporated, 18 Geo. 2, c. 15.

Charter of incorporation of the Royal College of Surgeons, 40 Geo. 3, 22d March, 1800.

Charter altering titles of Master, &c. to President, 3 Geo. 4, 13th Feb. 1822.

Charter creating class of Fellows, 7 Vic. 14th Sept. 1843.

Apothecaries' act. No person (except those previously in practice) to practise as an apothecary in England or Wales without examination, 55 Geo. 3, c. 194.

Incorporation of the Pharmaceutical Society of Great Britain.

GENERAL PHARMACY.

(Operations and Instruments.)

JOHN QUINCY, M. D. Preflectiones Pharmacutica, or a Course of Lectures in Pharmacy, Chemical and Galenical, explaining the whole doctrine of that Art. Edited by Dr. F. Shaw. Lond. 1723. 4to.

</table>
A.D. 1832  Dr. J. Stephenson, Med. Zoology and Mineralogy. 8vo. 1832.

1833  John Lindley, Ph. D. Flora Medica; a botanical account of all the more important plants used in medicine in different parts of the world. Lond. 1838. 8vo.

Dispensatories.

(Containing the natural and medicinal history of the various substances.)

1718  John Quincy, M. D. Pharmacopæia officinalis et extemporanea, or a complete English Dispensatory. Lond. 1718. 8vo.—12th ed. 1742.—14th ed. 1769.

1747  Robert James, M. D. Pharmacopæia Universalis, or a New Universal English Dispensatory. Lond. 1747. 8vo.—2d ed. 1752.

1753  [William Lewis, M. D.] The New Dispensatory. Lond. 1753. 8vo. (Author's name omitted) 3d ed. Lond. 1770. (After the author's death several editions were published in London: 5th ed. 1785: 6th ed. 1799)—In Edinburgh improved editions, forming the Edinburgh New Dispensatory, were published successively by Dr. Webster (1786), Dr. Duncan (1788), Dr. Rotheram (1794; 6th ed. 1801), and Dr. Duncan, jun. (1800; 3d ed. 1806.)

1815  S. Rootsey, General Dispensatory. 12mo. Brist.

1824  Thomas Cox, M. D. New London Dispensatory. Lond. 1824. 8vo.

National Pharmacopæias.

1618—1836  Pharmacopæia Londinensis. The first edition of this work appeared in 1618. Subsequently numerous reprints and editions have been published; viz. in 1621, 1627, 1632, 1639, 1650, 1651, 1677, 1678, 1682, 1699, 1720, 1721, 1722, 1724, 1751, 1736, 1746, 1747, 1748, 1757, 1762, 1763, 1771, 1786, 1787, 1788, 1809, 1815, 1824, 1836, and 1851.

Numerous translations and criticisms of these various editions have from time to time been published. The following require to be specially noticed:

1691  Dr. G. Bate. Pharmacopæia Batanae, by Fuller. 12mo.

1811  R. Phillips. An Experimental Examination of the last edition of the Pharmacopæia Londinensis, and of Dr. Powell's translation. Lond. 1811. 8vo.

1818  Gray's Supplement to the Pharmacopæias. 3d ed. 1824.—4th ed. by Theophilus Redwood. Lond. 1848. 8vo. (pp. 1070.)

1826  J. Rennie. New Supplement to the Pharmacopæias. 8vo. 4th. ed. 1837.

1721—1841  Pharmacopæia Edinburgensis. (The first edition of this work appeared in 1699, and subsequent ones in 1721, 1722, 1727, 1735, 1744, 1755, 1774, 1783, 1784, 1788, 1792, 1803, 1804, 1806, 1813, 1817, 1839, and 1841.)

1807—1850  Pharmacopæia Dublinensis. (A specimen Pharmacopæia was circulated among the members of the Dublin College of Physicians in 1794, and another in 1805. The first published Pharmacopæia appeared in 1807. A new edition was published in 1829, and the last edition, revised and considerably altered, was published in 1850.)

The Danish and Norwegian literature was common to both countries until their political separation in 1814, when Norway was united with Sweden. The language used in Norway in writing, and by all educated persons, in speaking, is identical with the Danish. Hence, then, every medical work published in Denmark till 1814 may be considered as also belonging to Norwegian literature. Since that year, no work on Pharmacology has been published in Norway. The king has, however, appointed a committee to prepare a new pharmacopoeia for that country. The Pharmacopoeia Danica has hitherto been used there. Several articles on Pharmacology have appeared in the Norwegian periodical, Eyr, et medicinsk Tidskrift, 11 vols. Commenced in 1826, and continued by Dr. Holst till 1837.
RUSSIAN EMPIRE.

a. To the end of the 10th century, A.D.

During this epoch there were no professors of the healing art. Medicine was practised on emergencies by the heads of families (Medicina domestica).

Quas employed as a national drink.

Baths in popular use.

b. From about the end of the 10th century to the end of the 17th century, A.D.

Subsequently to the introduction of Christianity into Russia (988, A.D.) medicine was practised by regular professors, most of whom were foreigners (English, Dutch, and German).

990
John Smer or Smera, a Pole, the first physician mentioned by name.

1634
Herbal (in Russ.) with figures.

1653
Commencement of commercial intercourse with England during the reign of Ivan Vassilievitch. Subsequently to this period, English medical men visited Russia; some being sent, at the request of the Czar, by the English sovereign.

1681
Establishment of the Imperial Court Dispensary, in the Kreml, district, in Moscow; and appointment of James Frechem, an Englishman, to the office of Apothecary to it.

1588
A manuscript medicine book translated from the Polish into Russian. (The Polish original bears date 1423, A.D., and states that it was a translation from Roman authorities.)

1620
Establishment of the Apotekarski Prikaz or Apothecaries’ Board [Apothekerbehörde].

To this Board was committed the supervision of the court dispensary, the appointment of military surgeons, the establishment of new military dispensaries, the payment of the salaries of the medical officers, and the settlement of disputes. (In 1707, this received the name of Apothecaries’ Chancery [Apothekercanzlei], and, in 1725, that of Medical Chancery [medizinischen Kanzlei].)

1631
Military dispensaries instituted.

1657
Prohibition of private trade in rhubarb, and establishment of the Crown monopoly. (In 1762 the monopoly ceased.)

1665
Physic gardens established at Moscow.

γ. From the commencement of the 18th century to the present time.

During this epoch, medicine, as a science, was established and domesticated in Russia.

Peter the Great (who reigned alone from 1696 to 1765) greatly encouraged medicine, as well as the arts and sciences generally. He established public medical institutions (hospitals, schools, libraries, museums, &c.); botanical gardens, &c.

—He promoted the translation of foreign medical books into the Russian language; and encouraged the establishment of chemical manufactories.

1701—1713
Appointment of eight private dispensaries in Moscow in addition to the two Royal ones.

1721
The establishment of private dispensaries, in St. Petersburg and other places, ordained.

1763
Foundation of the Imperial Medical College by Catherine II.

1765
Pharmacopoeia castrensis. 8vo.

1770
John George Mode, for many years an apothecary at St. Petersburg. Author of various chemical and pharmaceutical works.

1778
Pharmacopoeia Rossica. Petrop. 1778, 8vo.—1782, 8vo.—1798, 8vo.—1799, 8vo.—1800. Rec. opus plane novum, 1803, 8vo.—Lips. 1821, 8vo.—Ed. nov. Lips. 1830.

1778
Pharmacopoeia castrensis Rossica. Petrop. 1778, 4to.

1784
Dr. H. Bacharacht. Pharmacopoeia Rossica ac Pharmacopoeia castrensis et navalis Rossica. Petrop. 8vo. (A German translation, by K. F. Schröder, published at Copenhagen, 1788.)

1783—1809

1790

1790
Sievre’s, an apothecary, went to Siberia under the auspices of Catherine II., with the view of promoting and improving the cultivation of Siberian rhubarb.

1802

1802

PORTUGAL.

(From the establishment of the Monarchy, A.D. 1134.)

1449 Privileges granted by Alfonso V. to the Apothecary Ananias on his arrival in Portugal from Ceuta. (First legislative notice of Pharmacy subsequent to the foundation of the monarchy.)

1450 Inspection of Drugs ordained.

1461 Physicians and Surgeons prohibited from preparing medicines; and Apothecaries prohibited from practising medicine and surgery.

1521 Examinations of Apothecaries ordained.

ADDENDA.—UNITED STATES OF AMERICA.

1852  A. Clapp, M.D. A Synopsis or Systematic Catalogue of the Indigenous, Naturalized, Flowering, and Filicoid Medicinal Plants of the United States, etc.]
II. ORGANIC BODIES.

Under this division are included those vegetables and animals, with their educts and products, which are employed in medicine.

I adopt L. Gmelin's definition of an organic compound, and which I have already stated (see vol. i. p. 291, foot-note).

For reasons which have been assigned in the Preface to the first volume, certain medicinal compounds, which consist of an organic acid and an inorganic base, have been referred to the first division of this work, which treats of inorganic bodies.

I. Vegetabilia.—Vegetables.

These may be conveniently arranged in four classes, as follows:

1. Cryptogamia; scotyledonous, asexual, or flowerless.
   - Stem and leaves distinguishable
   - Thallogea.

2. Phanerogamia; sexual, or flowering.
   - Cotyledons solitary or alternate; wood of stem youngest in the centre
   - Endogene.

I. Cryptogamia, Linn.—Cryptogams or Flowerless Plants.

Acotyledones, Jussieu.—Exembryonates of Arhizae, Richard; Aegae or Athetogamæ, Auctorum; Nemæ, Fries.

Characters.—Sexual organs, and, consequently, flowers and true seeds, absent. Reproduction taking place either by spores, which are enclosed in cases called theca, or imbedded in the substance of the plants; or else by a mere dissolution of the utricles of cellular tissue. Spores destitute of embryo and cotyledons, germinating at no fixed point, but at any part of their surface.

VOL. II.—4
Class I. Thallogenæ.—Thallogens.

Anandrea, Link; Acotyledonæ, Agardh; Homoneerm, Fries; Cryptophyta, Link; Thallogynæ, Endlicher; Amphigenæ, Ad. Brong.

Characters.—Substance of the plant composed chiefly of cellular tissue, devoid of spiral vessels. Cuticle destitute of stomata, or breathing pores. Stem and leaves undistinguishable. No opposition of stem and root.

This class includes three orders:

I. Thallogenæ nourished through their whole surface by the medium in which they vegetate.

II. Thallogenæ nourished through their thallus (spawn or mycelium) by juices derived from the matrix.

ORDER I. ALGÆ, D.C.—ALGALS.

Algales, Lindley.

Characters.—Cellular flowerless plants, nourished through their whole surface by the medium in which they vegetate; living in water or very damp places; propagated by zoospores, coloured spores, or tetraspores.

Properties.—None of the plants of this order are poisonous. Some of them are nutritive, emollient, and demulcent: these properties they owe to the presence of mucilage (carrageenin), starch, sugar (mannite), and a little albumen. The peculiar mucilage of sea-weeds will be more fully noticed hereafter (see Chondrus crispus). It differs, says Dr. Stenhouse, from ordinary gum, for, when digested with nitric acid, it yields oxalic, but neither mucic nor saccharic acids.

Mannite is probably obtainable in greater or less quantity from most if not all sea-weeds. It was procured from eight out of nine species examined by Dr. Stenhouse. He could not detect it in Ulva latissima. The following is a list of the Algæ which he examined, arranged in order, according to the quantity of mannite which they severally yielded:

1. Laminaria saccharina (12.15 per cent. of mannite).
2. Halidrys siliquosa (5 or 6 per cent.).
3. Laminaria digitata.
4. Fucus serratus.
5. Alaria esculenta.
6. Rhodomenia palmata (2 or 3 per cent.).
7. Fucus vesiculosus (1 to 2 per cent.).
8. Fucus nodosus.

Fig. 146.

Esculent Sea Weeds.

a. Rhodomenia palmata (or Dulse).
b. Rhodomenia ciliata.
c. Laminaria saccharina.
d. Iridsea edulis.
e. Alaria esculenta.
f. Ulva latissima.

The presence of such a large proportion of potash and phosphoric acid in plants growing in seawater, which contains so small a proportion of these ingredients, is very remarkable. There is reason, however, to believe that the quantity and constitution of the ash are liable to very considerable variation, depending on the locality, season, age of the plant, &c. A vermi­fuge property has been ascribed to some algal.

Lennec tried the influence of an artificial "marine atmosphere" (air impregnated with the vapour of fresh sea-weed) on consumptive patients, and was impressed with an idea of its efficacy; but experience has not confirmed his favourable opinion of its beneficial influence; moreover, the inhabitants of sea-coasts, like those of inland districts, are the subjects of phthisis.

Sub-order I. Confervaceae, Endl.—Confervales.

Characters.—Vesicular, filamentary, or membranous alga, propagated by sporidia (endogenous cells, or a gelatinous substance which is ultimately formed into cells), which are produced at the expense of the endochrome of one or more cells, or sometimes by the copulation of distinct individuals, and discharged by the opening or absorption of the mother cell.

Properties.—These are similar to those of the Order, and which I have already noticed (see ante, p. 50).

1. Confervales of mineral waters.—Con­fervales are peculiarly abundant in both hot and cold sulphureous springs. Calothrix nivea (Fig. 147), the Conferva nivea of Dillwyn, has been found in the sulphur springs of Yorkshire, Durham, and Aix-la-Chapelle. The same, or an allied species, was found by Dr. Daubeney in the hot sulphur springs of Greoonix, in Provence. Oscillatoria labriformis—the Tremella thermals of some writers—is one of the most common species in the hot sulphur springs, and other thermal waters of Germany, France, and

5 Schweitzer.
7 Tract. on Diseases of the Chest, by Dr. Forbes, p. 399.
9 Op. citato.
VEGETABLES.—NAT. ORD. ALGÆ.

Italy. In the Karlsbad waters, *Spherozyga Jacobi* (Fig. 148), and several species of *Oscillatoria*, have been detected. Humboldt found *Oscillatoria calida* in the thermal waters of New Granada.

The organic substance found in mineral waters, and variously called *barégrine* by Longchamp, *zoogen* by Gimbernat, *theoothermin* by Monheim, and *glairine* by Anglada, derives its origin from confervals. It is a glairy or mucus-like substance, which is said to communicate the flavour and odour of flesh-broth to the water in which it is contained. In the preparation of artificial sulphur baths, animal gelatine is sometimes used to represent the *barégrine* (see ante, vol. i. p. 478).

The confervals, under the influence of light, decompose water, retain the hydrogen, and evolve the oxygen. Robiquet obtained, from the Neris water, gas containing 44 per cent. of oxygen, derived from the *Oscillatoria* labyrinthiformis; and he ascribed the medicinal qualities of these waters to the presence of this very oxygenated air. "Dr. Edwards," says Robiquet, "has shown that the air contained in water has a great influence over the life of batrachians, and it is probable that, in some cases, our organs may also be more or less influenced by it."

2. Confervals employed in medicine. — *Yeast* is referred to Algae by Kützing, who calls it *Cryptococcus Fermentum*. It is more commonly, however, regarded as a fungus, and as such will be noticed hereafter. (See Fungi.) With this doubtful exception, none of the Confervals are employed, at the present day, in medicine. *Nostoch commune*, or star-jelly, of which, formerly,

---

3 *Phycologia generalis.*
CONFERVALS IN PHARMACEUTICAL LIQUIDS.

the most extraordinary superstitions were entertained, and _Conferva rivularis_, or crow silk, recommended by Murray for trial in asphyxia, asthma, and phthisis, on account of its evolving oxygen in solar light, have never been used in rational medicine.

3. CONFERVALS DEVELOPED IN PHARMACEUTICAL AND OTHER LIQUIDS.—The vesicular and filamentous plants which grow in various chemical solutions and to the naked eye appear like gelatinous or cottony masses, are considered by some botanists to be Algals. Kützing refers them to the genera _Cryptococcus, Ulvina, Hygrocris, Sirocris, Leptomitus, and Chamanema._

![Fig. 153.](image)

_Sirocris stibica_ (in a solution of emetic tartar).

_Leptomitus phosphoratus_ (in phosphoric acid from bones).

But these minute plants are regarded by some eminent authorities as the spawn or mycelium of various moulds, or, in other words, as imperfect mucedinous fungi. "It is true," says the Rev. M. J. Berkeley, "that moulds will vegetate in fluids, but, as soon as they assume their normal form, there is a distinction between the immersed and free portion." If, however, they fructify under water, which, according to Kützing, they do, their algaceous nature is, I apprehend, proved.

4. ESCULENT CONFERVALS.—Some few of the Confervals are cooked and brought to table under the name of _laver_; but the amount of nourishment which they contain is very small. They are species of _Porphyra and Ulva._

---

1 See the articles "Nostock," in the _Dict. Univ. de Mat. Méd._, t. iv. p. 635, 1832; and "Calisolum," in James's _Medicinal Dictionary_, vol. ii.

2 _Appar. Medicaminum_, t. v. p. 559, 1790. Pliny (Hist. Nat. lib. xxvii. cap. 45) says he knew a labourer who fell from the top of a tall tree, and thereby broke nearly every bone in his body, and who, being covered with a river _conferva_, kept moist by his own water, was cured in an incredibly short space of time. He adds, that the term _conferva_ is derived from "conferruinando," in allusion to the supposed consolidating properties of this plant.

3 For some notices of these plants, the reader is referred to my paper _On the Microscopic Vegetations developed in Pharmaceutical Liquids_, in the _Pharmaceutical Journal_, vols. vii. and viii. 1848.
1. Porphyra laciniata, Agardh.—Laciniated Purple Laver.

Fig. 154.

Porphyra umbilicalis, Kützing; Ulva umbilicalis, Eng. Bot.—The fronds are delicately membranaceous, deeply and irregularly cleft into several broad segments. Their colour is deep purple, but, when not in a state of perfection, it tends to livid olive. "Under the microscope, the whole frond appears to be divided into squares, in the manner of a tessellated pavement, and within each square are four purple granules or spores, which constitute the fructification and the whole colouring matter of the frond" (see Fig. 154, a). Abundant on all our shores. This plant is pickled with salt, and sold in London as laver. The London shops are said to be supplied with it from the coast of Devonshire. When stewed, it is brought to the table and eaten with pepper, butter, or oil, and lemon juice or vinegar. Some persons stew it with leeks and onions. It is generally taken as a luxury; but it might be employed with advantage, by scrofulous subjects, as an alternative article of diet. In the absence of other vegetables, it might be valuable as an antiscorbutic to the crews of our whaling vessels cruising in high latitudes, where every marine rock at half-tide abundantly produces it.

Porphyra laciniata.

a. Small portion of the frond, showing the quaternate granules (magnified).

2. Ulva latissima, Greville.—Broad Green Laver.

Ulva Lactuca var. latissima Lightf.; Green Sloke; Oyster Green.—The fronds are bright herbaceous green, becoming tinged with brown in old age and decay. They are oblong, roundish, waved, and very tender (see Fig. 146, b). The granules are quaternate, and densely cover the whole frond. It is said to be used at table under the name of green laver, being cooked in the same way as the Porphyra laciniata, to which it is greatly inferior. It is rarely taken when the latter can be procured. I have never found it in the London shops.

Sub-order II. Phyceæ, Endl.—Sea Wracks.

Fucaceæ, Lindl.; Aplosporeæ, Decavane.

Characters.—Cellular or tubular algæs propagated by spores (endogenous cells), contained in superficial, often bladdery (utricles) cells, produced singly out of endochrome, consisting of a simple nucleus clothed by its proper cellular membrane (episore), and discharged by the opening of a transparent mother cell (perisore).

Properties.—Similar to those of the order (see ante, p. 50). To this order several esculent species belong: such as Laminaria digitata, called by the English seawirdles, by the Scotch Tangle; and Alaria esculenta (Fig. 146, e), termed Batterocks, Hen-ware, or Money-ware. These, as well as several other species of this order, viz., Laminaria saccharina (Fig. 146, c), and Halidrya siliculosus, have been already referred to as containing mannite (see ante, p. 50).

The only species used for medicinal purposes which it will be necessary to notice is Fucus Vesiculosus.

1 Harvey, Phycologia Britannica, vol. i. pl. xii. 1846.
3. Fucus vesiculosus, Linn.—Common Sea Wrack.

**Sex. Syst. Cryptogamia, Alge.**

(Herea cum fructu, Offic.)

**History.**—Theophrastus mentions several species of Alge (φυκα). Fucus vesiculosus is sometimes termed quercus marina, bladder fucus, and common sea-ware, kelp-ware, and black tang.

**Botany. Gen. Char.**—Frond linear, either flat, compressed, or cylindrical, dichotomous (rarely pinnated), coriaceous. Air-vessels [vesiculae] when present innate, simple. Receptacles either terminal or lateral, filled with mucus, traversed by a net-work of jointed fibres, pierced by numerous pores, which communicate with immersed spherical conceptacles, containing parietal spores, or antheridia, or both (Harvey).

**Sp. Char.**—Frond plane, linear, dichotomous, entire at the margin. Air-vessels roundish-oval in pairs. Receptacles mostly elliptical, terminating the branches (Greville).

Very variable; but the varieties pass so insensibly into each other that it is difficult to define them strictly.

**Hab.**—Sea-shores. Very common everywhere.

**Physical Properties.**—Its substance is thickish, flexible, but very tough. Its colour is dark, olivaceous, glossy green, paler at the extremities, and becomes black by drying. Its odour is strong; its taste nauseous.

**Composition.**—It has been analyzed by Stackhouse, by Gaultier de Claubry, by John, and by Fagerstrom. The following appear to be its constituents: Cellulose, mucilage (carrageenin), mannite, odoruous oil, colouring and bitter matters, and various salts.

The following table shows the composition and proportion of ash of Fucus vesiculosus of different localities:

5 Schweiziger.

*Dict. Scienc. Nat. xviii. 500.*

*Schweizer's Journ. xiii. 461.*

*James, ibid.*

*Forchhammer.*
CHEMICAL CHARACTERISTICS.—By treating the distilled water of Fucus vesiculosus with ether, a semi-solid white oil is extracted, which is the odorous principle. The aqueous decoction of this plant is neutral, and contains in solution mucilage (see carrageenin) and various salts. It yields, with chloride and starch, faint traces only of iodine, sometimes none at all. But if alcohol be added, by which the mucilage and a part of the sulphates are thrown down, the alcoholic liquor evaporated, and the residue mixed with potash, then calcined, and afterwards treated with hydrochloric acid to disengage hydrosulphuric acid, we may sometimes detect iodine in the filtered liquor by the deep blue colour formed on the addition of starch and chlorine.¹

By combustion in the open air, this plant yields the ash called kelp; and by incineration in a covered crucible it gives a charcoal, termed vegetable ethiops.

PHYSIOLOGICAL EFFECTS.—During the winter, in some of the Scottish islands, horses, cattle, and sheep are fed on it.² Its local action is deterrent, and, perhaps, discutient. Its remote effects are probably analogous to those caused by small doses of iodine, modified by the influence of salts of sodium and calcium.

USES.—Frictions of the plant, with its contained mucilage, were employed, with supposed advantage, by Dr. Russell,³ in glandular enlargements and other scrofulous tumours: the parts were afterwards washed with sea water. He also gave internally the expressed juice of the vesicles in glandular affections.⁴

ETHIOPS VEGETABILIS; Vegetable Ethiops.—This is prepared by incinerating Fucus vesiculosus in a covered crucible. It is composed of charcoal and various salts (see supra). When hydrochloric acid is added to it, traces of sulphuretted hydrogen are frequently evolved. By digesting the ethiops in water, and testing the solution with nitric acid and starch, I have sometimes failed to obtain the blue colour indicative of the presence of iodine. It has been exhibited in bronchocele and scrofulous maladies. Dr. Russell⁵ says it far exceeds burnt sponge in virtue. It has been employed also as a dentifrice. The dose of it is from ten grains to two drachms.

Sub-order III. FLORIDEÆ, ENDL.—ROSE-TANGLES.

CERAMIACEÆ, Lindl.; CHORISTOSTOMARIAE, Decaisne.

CHARACTERS.—Cellular or tubular algæ propagated by thece (favella vel favellidia, coccidia vel keramidia), composed of granules [spores?] contained within a cellular or gelatinous perisporangium; and by sphaerospores (or tetraspores), composed of four (or three) spores in a transparent perispore.

PROPERTIES.—Several species of this sub-order are esculent. They owe this property to the mucilage, starch, mannite, and perhaps a little albumen, which they contain. Besides the species presently to be described, Irídeæ elatæ (Fig. 145, d) and Rhodómeniæ palmaæ (Fig. 145, a), which is cried about the streets of Edinburgh under the name of dulse, may be mentioned as illustrative examples of esculent species.

4. CHONDRAUS CRISPUS, Grev.—CARRAGEEN OR IRISH MOSS.

SEX. SYST. Cryptogamia, Algae.

(Planta, Offic.)

SYNONYMES.—Chondraus polymorphus, Lamour; Sphaerococcus crispus, Agardh; curled chondrus (chondrus, from κόρας, cartilage).

HISTORY.—Carrageen, Irish, or pearl moss, was introduced into medicine by Mr. Todhunter, of Dublin.⁶

BOTANY. GEN. CHAR.—Frond cartilaginous, nerveless, compressed or flat, flabelliform, dichotomously cleft: formed internally of three strata; the inner, of

¹ Guibourt, Hist. des Drog. Amer. ed. ii. 46.
³ Greville, Algae Brit. xx.
densely-packed longitudinal fibres; the *medial*, of small roundish cells; the *outer*, of vertical, coloured, moniliform filaments. *Fructification*: 1, prominent *tuberces (nemathecia)* composed of radiating filaments, whose lower articulations are at length dissolved into *spores* (?); 2, *tetraspores* collected into sori, immersed in the substance of the frond (Harvey).

**Sp. Char.**—Frond stipitate, thickish, cartilaginous, flat or curled, segments wedge-shaped, very variable in breadth; apices truncate, submarginate, or cloven: axes obtuse; sori elliptical or oblong, concave on one side (Harvey). Fronds from 2 or 3 to 10 or 12 inches long: their substance cartilaginous, in some varieties approaching to horny, flexible and tough; their *colour* deep, purple-brown, often tinged with purplish-red, paler at the summit, becoming greenish, and at length white in decay.

This, says Dr. Greville, is the Proteus of marine Algae. The varieties are innumerable, and pass into one another so insensibly that it is almost impossible to define them.

Mr. D. Turner enumerates the following varieties:—

1. *vires'; frond submembranaceous, branches dilated upwards, flattish, extreme segments long and acuminate.
2. *stellatus'; frond submembranaceous, branches dilated upwards, divided at their apices into very numerous clustered short laciniae.
3. *equalis'; frond cartilaginous, thick, all the branches equal, linear, the extreme segments obtuse.
4. *filiformis'; frond cartilaginous, subcylindrical, branches nearly linear, apices long and acuminate.
5. *patens'; fronds subcartilaginous, channelled on one side, dichotomous, angles of the dichotomies patent.
6. *laceris'; frond cartilaginous, compressed, apices very narrow, elongated, branched.
7. *sarmiensis'; frond between coriaceous and cartilaginous, branches slightly channelled on one side, dilated upwards, apices rounded and emarginate.
8. *planus'; frond subcoriaceous, flat, wide, branches linear, apices obtuse.
9. *geniculatus'; frond cartilaginous, compressed, branches nearly linear, tubercles subglobose, black, frond bent, and often broken at the tubercles.

According to Ormancey, Carrageen is a zoophyte which he proposes to call *Antipathes polymorphus*. Unlike the fuc; he says, it has no canal, nerves, or roots; but, like the zoophytes, it has voluntary motion of tentacles, sensibility, and two distinct bodies, one secreted by the other, simulating a plant.

**Hab.**—On rocks and stones on the sea-coast; very common.—**Perennial**: spring.

**Preparation.**—For dietetical and medicinal uses, it is collected on the west coasts of Ireland (especially in Clare), likewise, according to Kohl, in Antrim; washed, bleached (by exposure to the sun), and dried.

In Ireland, it is sometimes employed by painters and plasterers as a substitute for size.

---

*Fig. 156.*

1. Plant with sori (*natural size*).
2. Segment with sori.
3. A segment and sori vertically divided.
4. Seeds or spores.
5. Tetraspores from the sori (*magnified*).
Along with Chondrus crispus, other allied species, especially Ch. mamillatus, are sometimes collected (see Fig. 158).

**Physical Properties.**—The carrageen or Irish moss of commerce (muscus carragениcus) consists of fronds, which are usually from two to three or four inches long, dry, crisp, mostly yellowish or dirty white, but intermixed with purplish red portions, inodorous, or nearly so, with a mucilaginous taste. The frond is formed internally of three strata; the inner, of densely-packed longitudinal fibres; the medial, of small roundish cells; the outer, of vertical, coloured, moniliform filaments.4

In warm water, the dried commercial frond swells up, and, when boiled, almost entirely dissolves. If the swollen and partially-dissolved frond be examined by the microscope, it is seen to consist of very minute, somewhat fusiform cohering cells. A calcareous, meshy crust (consisting of various species of Flustra) is frequently found on the frond.

**Chondrus mamillatus** is found in commercial carrageen. Some samples I found to be principally composed of this species.3 The frond of this plant is more or less channelled; but the species is best distinguished by the fructification; in Ch. crispus the subhemispherical capsules are imbedded in the disk of the frond, producing a depression on the opposite side (see Fig. 156); in Ch. mamillatus, the spherical capsules are scattered over the disk of the frond, and are supported on little short stalks (Fig. 158).

**Composition.**—It has been analyzed by Herberger3 and by Feuchtwanger.4

Subsequently, iodine has been detected in it by Sarphati,5 and both iodine and bromine by Grosse.9 (For the composition of the ashes, see p. 51.)

**Carrageenin.**—The mucilaginous constituent of carrageen moss is termed by some writers *vegetable jelly*, or *vegetable mucilage*, by others *petitin*. It appears to me to be a peculiar modification of mucilage, and I shall, therefore, call it *carrageenin*. It is soluble in boiling water, and its solution forms a precipitate with diacetate of lead and silicate of potash, and, if sufficiently concentrated, gelatinizes on cooling. Carrageenin is distinguished from ordinary gum by its aqueous solution not producing a precipitate on the addition of alcohol; from starch, by its not assuming a blue colour with tincture of iodine; from animal jelly, by tincture of nut-galls caus-

---

ing no precipitate;\(^1\) from pectin, by acetate of lead not throwing down anything, as well as by no mucic acid being formed by the action of nitric acid.

According to Schmidt,\(^2\) the cell-walls of carrageen do not essentially differ from the contents of the cells; for, when the plant is boiled in water, the whole swells up and forms a mucilage, which may be expressed through a linen cloth, leaving behind the \textit{Flustra} and small crustacean with which this alga is covered. By digestion for a short time with dilute sulphuric acid in a water-bath, the whole plant is converted into sugar and gum.

The composition of carrageenin dried at 212° F., according to Schmidt, is represented by the formula \(\text{C}_{12}\text{H}_{20}\text{O}_{10}\); so that it appears to be identical with starch and sugar. Mulder,\(^3\) however, represents it by the formula \(\text{C}_{12}\text{H}_{10}\text{O}_{19}\).

**Chemical Characteristics.**—The presence of carrageenin in the decoction is demonstrated by the tests before enumerated. No iodine is recognizable by nitric acid and starch. Oxalate of ammonia detects lime (or calcium) in solution, while nitrate of silver points out the presence of chlorine. Guibourt\(^4\) could recognize neither sugar nor magnesia.

**Physiological Effects.**—Carrageen moss is nutritive: its mucilaginous matter acts as an element of respiration (see ante, vol. i. p. 116), while its inorganic constituents (phosphate of lime, potash, salts, &c.) may also serve some useful purpose in the animal economy. It is generally regarded as being readily digestible. Medicinally, it is emollient and demulcent (see ante, vol. i. pp. 207-8).

**Uses.**—It is a popular remedy for pulmonary complaints (especially those of a phthisical character), chronic diarrhoea and dysentery, scrofula, rickets, enlarged mesenteric glands, irritation of bladder and kidneys, &c. As a culinary article, it has been employed as a substitute for animal jelly, in the preparation of blanc-mange, jellies, white soup, &c. A thick mucilage of carrageen scented with some prepared spirit is sold as bandoline, fixature, or elysphitique, for stiffening the hair and keeping it in form.

**Administration.**—It is usually exhibited in the form of decoction or jelly. It has also been employed in combination with chocolate or cocoa.

1. **Decoctum Chondri; Decoction of Carrageen or Irish Moss.**—Macerate half an ounce of carrageen in cold or warm water, during ten minutes; then boil in three pints of water for a quarter of an hour. Strain through linen. When properly flavoured, it may be used as a tisan or common drink. By doubling the quantity of carrageen, a mucilage (mucilago chondri) is procured. Milk may be substituted for water when the decoction is required to be very nutritious. A preparation of this kind has been called \textit{lac analepticum}. Sugar, lemon-juice, tincture of orange-peel, essence of lemon, or other aromatics, as cinnamon or nutmeg, may be employed as flavouring ingredients.

2. **Gelatina Chondri; Carrageen Jelly.**—This may be prepared by adding sugar to the strained decoction and boiling down until the liquid is sufficiently concentrated to gelatinize on cooling; or by employing a larger quantity of carrageen. If milk be substituted for water, \textit{carrageen blanc-mange} is obtained. Sugar and other flavouring ingredients may be employed, as above mentioned.

3. **Pasta Cacao Cum Chondro; Pasta Cacao cum Lichene Carragheno, Ph. Dan.; Carrageen Cocoa.**—The Danish pharmacopeia gives the following directions for its preparation: Roasted and decorticated Cacao Seeds reduced to a very subtile mass in a warm iron mortar; Powdered White Sugar, of each 1lb; Powdered Carrageen 3ij. Mix, and form into quadrangular sticks. Clarus and Radius\(^5\) direct \textit{carrageen}, or \textit{white chocolate}, to be prepared as follows: Cocoa Paste 3iv; Powdered Carrageen 3vj; White Sugar 3iv; Flour q. s. (3vj). Mix.—These pastes are to be used like common cocoa or chocolate.

1 Berlin. \textit{Jahrb. xxxiv} Abth. i. 1834.  
3 Pharmaceutisches Central-Blatt für 1838, S. 600; and The Chemistry of Animal and Vegetable Ph"y"sology, by Fromberg and Johnston, Part ii. p. 529.  
5. PLOCARIA CANDIDA, Nees.—CEYLON MOSS.

_Sex._ Syst. Cryptogamia, Algæ.

(Planta, Ofic.)

**Synonymes.**—_Gracilaria lichenoides_, Greville; _Sphaerococcus lichenoides_, Agardh; _Gigartina lichenoides_, Lamouroux; _Fucus lichenoides_, Turner; _Fucus amylacceus_, O'Shaughnessy; _Jaffna Moss_; _Edible Moss._—According to Rumphius, it is called by the Malays _Sajar carang_ and _Agar ayar carang_; at Amboyna, it is termed _Aysana_ and _Aytana_ (h. _e. arbucula ramosa_), and _Rumeyar vaccar_; at Java, _Buhung_; at Macassar, _Dongi dongi_; and at other places, _Lottu lottu_ and _Collocane._

**History.**—It seems to have been long known and used in the East. It has been described by Rumphius, Gmelin, Turner, Nees, and Agardh. About the year 1837 it was introduced into England by Mr. Previté; and in the year 1840 public attention was drawn to its useful properties by Messrs. Sigmoid and Parre.

**Botany. Gen. Char.**—_Frond_ composed of large oblong-cylindrical cells containing granular endochorne, those of the surface forming moniliform, densely-packed filaments. _Fructification_ of two kinds: 1. hemispherical, pinnate _coccidium_, containing a glomerule of oblong spores on a central placenta, within a pericarp of moniliform, densely crowded filaments; 2. oblong _tetraspores_ imbedded in cells of the surface (Endlicher).

**Sp. Char.**—_Frond_ cartilaginous, cylindric, filiform, much and irregularly branched; branches smooth, spreading, acute, somewhat fastigiate. _Coccidia_ sessile, scattered.

Rumphius mentions four kinds of _Alga coralloides_, which he distinguishes as the _prima_, _secunda_, _tertia_, and _quarta_; and he has figured three kinds. Nees figures two plants—one fertile, the other sterile. Turner notices two varieties: _B edulis_ is a smaller variety, and has a remarkably flexuose frond, more thin and less branched than _a_; its colour is quite white.

**Hab.**—Ceylon, at Jaffnapatam; the islands of the Indian Archipelago.

**Commerce.**—It is exported to China by the islands of the Indian Archipelago. Mr. Crawford says that it forms a portion of the cargoes of all the junks; the price on the spot where it is collected seldom exceeding from 5s. 8d. to 7s. 6d. per cwt. The Chinese use it in the form of jelly with sugar, as a sweetmeat, and apply it in the arts as an excellent paste. The gummy matter which they employ for covering lanterns, varnishing paper, &c., is made chiefly, if not entirely, from it.

**Physical Properties.**—Ceylon moss is in whitish or yellowish-white ramifying filaments of several inches in length. At the base the largest fibres do not exceed in thickness a crowquill; the smallest fibres are about as thick as fine sewing thread. To the naked eye the filaments appear al-
most cylindrical and filiform; but, when examined by a microscope, they appear shrunken and wrinkled. The branchings are sometimes dichotomous, at other times irregular. Dr. Farre states that in a bale opened at Mr. Batley's, about \( 1\text{st} \) appeared to bear fruitication. The tubercles (coccidii) are inconspicuous when dry, but when moist, are readily seen. They are hemispherical, about the size of a poppy-seed, and contain, according to Rumphius, a mass of minute, oblong, dark red spores. The consistence of Ceylon moss is cartilaginous. Its flavour is that of sea-weed, with a feebly saline taste.

**Composition.**—This algal has been examined chemically, in 1834, by Dr. O'Shaughnessy; in 1842, by Guibourt; and in 1843, by Wonneberg and Kreyssig, by Bley, and by Riegel.

1. **Mucilaginous Matter (Carrageenin)?; Vegetable Jelly; Pectin; Soluble gelatine.**—The mucilaginous or gelatinizing principle of Ceylon moss appears to me to agree very closely, if indeed it be not identical, with carrageenin. It has not hitherto been analyzed.

2. **Starchy Matter.**—This resides chiefly in the cortical portion of the algal. But the internal cell-walls become deeply stained purplish brown on the addition of iodine, as if they were composed of a starchy substance (starchy skeleton).

**Chemical Characteristics.**—By moistening Ceylon moss with a weak solution of ioduretted iodide of potassium, the plant acquires a purplish-brown or red colour; the younger and more delicate fibres becoming almost black. The change of colour is most intense in the cortical portion, but the internal cell-walls also become stained. By digestion in warm water, the plant softens and swells up. By boiling it in water, and then compressing and rubbing it gently between two plates of glass, the larger spheroidal cells are readily separated from each other: they are stained purplish-brown by iodine. The aqueous decoction is mucilaginous, and when sufficiently concentrated, gelatinizes on cooling. Iodine colours it a dull or purplish brown, and gives an intense dark purplish colour to the undissolved residue of the plant. If the plant be immersed in diluted hydrochloric acid, slight effervescence occurs, owing to the escape of carbonic acid evolved by the action of the hydrochloric acid on carbonate of lime.

**Physiological Effects.**—These are similar to those of Chondrus crispus (see ante, p. 59). Ceylon moss, therefore, may be denominated nutritive (chiefly as an element of respiration, see vol. i. p. 116), emollient, and demulcent. By the continued use of it at the table, the saline constituents of the plant would not be without some influence on the system.

**Uses.**—In the form of decoction or jelly, it is employed as a light and readily digestible article of food for invalids and children. The residue of the decoction is not devoid of nutritive matter, and might be served and eaten like cabbage or leguminous substances; especially when the alterative influence of the saline constituents is desired. The decoction or jelly of Ceylon moss may be employed in irrigation of

---

VEGETABLES.—NAT. ORD. ALGÆ.

the mucous surfaces, and in phthisis. It is not apt to occasion thirst, sickness, flatulence, heartburn, acidity, or diarrhoea.

ADMINISTRATION.—It may be administered in the form of decoction or jelly. Dr. O'Shaghnessy recommends that it should be steeped for a few hours in cold rain water, as the first step to its preparation: this removes a large portion of the sulphate of soda. It should then be dried by the sun's rays, and ground to a fine powder; for cutting or pounding, however diligently performed, still leaves the amylaceous matter so mechanically protected that the boiling may be prolonged for hours without extracting the starch. This grinding process, however, is seldom employed, the prepared plant being merely cut into very small pieces.

1. DECOCTUM PLOCARLE CANDIDE; Decoction of Ceylon Moss.—This is prepared by boiling the prepared moss in water, milk, or whey. One drachm of the plant will give a mucilaginous quality to eight ounces of water. Milk, sugar, orange or lemon juice and peel, wine, cinnamon, or other aromatics, may be used to communicate flavour. This decoction may be taken ad libitum.

2. GELATINA PLOCARLE CANDIDE; Jelly of Ceylon Moss.—Mr. Previté's directions for its preparation are the following: Boil half an ounce of the prepared moss in a quart of boiling water for twenty-five minutes, or until a spoonful of the liquid forms into a firm jelly within two or three minutes after it is removed from the boiler. Flavour with wine, a little cinnamon, lemon or orange juice and peel, and sweeten according to taste. Boil the whole for five minutes, and pass it two or three times through a jelly-bag or doubled muslin. Leave it undisturbed, and it will become a firm jelly in ten minutes. If it be required perfectly clear for table use, add the white of two eggs beaten up into a whip before the second boiling, and allow it to stand for a few minutes away from the fire, with some hot coals on the top of the boiler. When clear, pass it through the jelly-bag, and leave it to congeal. Should the jelly be required particularly firm, add an ounce of moss to the quart of water.

6. PLOCARIA HELMINTHOCORTON, Endl.—CORSICAN MOSS.

(Planta, Offic.)

HISTORY.—This plant has been in use for several centuries among the natives of Corsica, as a remedy for intestinal worms. In 1756, Vaucher sent it to Paris.1

BOTANY.—Gen. Char.—See Plocaria candida, p. 60.

Sp. Char.—Frond cartilaginous, terete, tufted, entangled. Stem filiform, creeping; branches setaceous, somewhat dichotomous, marked indistinctly with transverse streaks.

Hab.—The Mediterranean Sea, on the shores of Corsica.

PHYSICAL PROPERTIES.—Under the name of Corsican moss, is sold in the shops a mixture of various marine vegetables and animals. The essential, though usually smaller, part of the mixture is the Plocaria Helminthocorton; the remainder consists of Corallines, Sertularias, and Ceramiums, to the number of twenty species.2 Lamouroux states he found the remains of eighty species of marine plants.3 (See also T. C. Martius.)4

The structure of the frond of Plocaria Helminthocorton is "very peculiar, being exceedingly lax and cellular, with a consistence similar to that of the stems and leaf-stalks of some aquatic herbaceous phoenogamous plants, and having the appearance of articulations which do not actually exist."5 The fructification is scarcely

1 J. P. Schwendimann, in Schlegel's Thesaurus Mat. Med. t. iii. p. 181.
2 De Candolle, Essai sur les Propriétés Méd. p. 368, 9th ed.
3 Fée, Cours d'Hist. Nat. i. 147.
4 Grundriss d. Pharmakog. 12.
5 Greville, Alga Brit. p. 146.
ever seen. The plant has a reddish-gray colour externally, but is whitish internally. Its odour strong, marine, and disagreeable: its taste is saline.

Composition.—Bouvier\(^1\) obtained from 100 parts of Corsican moss, vegetable jelly [mucilage? carrageenin?] 60.2; vegetable fibre, 11.0; chloride of sodium, 9.2; sulphate of lime, 11.2; carbonate of lime, 7.5; iron, manganese, silica, and phosphate of lime, 1.7. Straub\(^2\) and Gaultier de Clauiry\(^3\) have subsequently detected iodine, but the quantity is small.

Chemical Characteristics.—Corsican moss effervesces with acids, owing to the carbonate of lime which it contains. The brown watery infusion is deepened in colour by sesquichloride of iron, and lets fall some brown flocculi. Tincture of galls does not alter it. Nitric acid and starch give no indication of iodine.

Physiological Effects.—Its effects are not very obvious. The vegetable jelly (mucilage) must render it somewhat nutritive; the iodine and saline matters alterative. Mr. Farr\(^4\) says that, after using the decoction for six or seven days, it acts as a diuretic and diaphoretic, and occasionally produces nausea and giddiness: after some time the stools become darker, present greenish specks, and are sometimes slimy.

Uses.—It has been principally celebrated as an anthelmintic against the large round worm (Ascaris lumbricoides). Bremsner\(^5\) ascribes its efficacy to chloride of sodium.

In 1822, Mr. Farr brought it forward as a remedy for cancer. He was led to try it from the circumstance of Napoleon Bonaparte having stated to Barry O'Meara that it was used in Corsica for dispersing tumours. Experience does not warrant us in ascribing any benefit to its employment in this disease.

Administration.—In powder, it is given in doses of a scruple to two drachms, mixed with honey or sugar; but the more usual mode of exhibiting it is in the form of decoction, prepared by boiling from four to six drachms of it in a pint of water; of this the dose is a wineglassful three times daily.

**Order II. Lichenes, Juss.—Lichens.**

**Lichenales, Lind.**

Characters.—Perennial, aerial thallogens, nourished through their whole surface by the medium in which they vegetate; always constituting a thallus, crust, or frond (receptaculum universal; blastema) formed of a cortical and a medullary layer, of which the former is simply cellular, the latter cellular and filamentous. Apothecia (fructus) consisting of a receptacle and a proligerous layer (lumina proliger a) composed of spores (spora) naked or enclosed in spore-cases (acei; theca), united to form a nucleus or disposed on a disk (discus).

Properties.—The tissue of lichens consists of cellular. Many of them contain amylaceous matters (lichen or fuscoid, and inulin) and their congeners gum and sugar, which render them nutritive, emollient, and demulcent. Bitter principles (estratic acid; pirollichinin) are sometimes found in lichens: these confer slight tonic properties. Colouring matters (thallochol, chrysophanic acid, &c.) are frequently present. Colorific principles (orcidin, erythric, lecanoric, and other acids), or principles which, under the combined influence of ammonium and oxygen, form colouring

\(^1\) Ann. de Chim. ix. 83, 1701.  
\(^3\) A Treatise explanatory of a Method whereby occult Cancers may be cured, 2d ed. 1835.  
\(^4\) Ann. de Chim. xciii. 134.  
\(^5\) Sur les Vers Intestin. 414.
matters (orcin, &c.), render some of the lichens valuable in the arts. Besides the before-mentioned bodies, several other vegetable acids (as the tartaric, oxalic, tannic, and lichesteoric) are found in the lichens. The oxalic acid is found in combination with lime; one lichen (Varioraria fuginea) contains 47 per cent. of calcareous oxalate. The ashes of the lichens constitute about 8 per cent. of the dried plants, and consist principally of the earths: the ashes of lichens growing on siliceous rocks contain more silica than those of lichens growing in other situations. It is deserving of especial notice that not a single poisonous lichen is known.

The lichens which I shall have to notice may be conveniently divided, according to their uses, into the esculent, the medicinal, and the tinctorial lichens.

1. Lichenes Esculenti Et Medicinales.—Edible And Medicinal Lichens.

The only lichen employed medicinally by British practitioners is Iceland moss (Cetraria Islandica). But several other lichens, whose medicinal qualities are in reality similar to, though much feebler than, Iceland moss are still kept in the London herb-shops, being occasionally employed as popular remedies. Those which I have met with are Peltidea canina, Scyophorus pyxidatus, and Sistca pulmonaria. These, as well as Gyrophora, Parmelia partitina, and Cladonia rangiferina, require a short notice.

7. Peltidea canina, Ach.—Ash-coloured Ground Liverwort.

This species, and also Peltidea rufescens, Ach., are sold in the herb-shops as Ground Liverwort. It formerly was in repute as a preservative against the bite of a mad-dog, and, mixed with half its weight of black pepper, it formed the pulvis antilyssus (âvri, against, and λύσα, canine madness) of the London Pharmacopoeia for 1721.

Fig. 161.

Fig. 162.

8. Scyophorus pyxidatus, Hook.—Cup-Moss.

Scyophorus pyxidatus, Hook, Engl. Fl. vi. p. 238; Cenomyce pyxidata, Ach. Syn.; Cladonia pyxidata, Schar. Lich. Helv. Spicil. p. 26; Lichen Pyxidatus, Linn.; Muscous pyxidatus, Dale, Pharm.; Cup-moss.—This species (frequently mixed with S. fimbriatus, Hook., and sometimes with S. coceferus, Hook.) is the Cup-moss of the shops. It was recommended by Dr. Willis as a remedy for hooping-cough. He gave it in draehm doses, in the form of powder, decoction, and syrup.

2 Pharmacutice Ratinalis, pars 2da, p. 49, 1675.
3 See, also, Dillenii, Dissertatio de Lichene Pyxidate, in Schlegel's Thesaurus Materia Medica, t. i. p. 307, Lipsiae, 1793.

Sticta pulmonaria, Hook, Engl. Fl.; St. pulmonacea, Ach. Syn. p. 233; Lichen pulmonarius, Linn.; Muscus pulmonaria, Dale, Pharm.; Tree Lungwort, Oak-Lungs.—This lichen has been analyzed by John, who found it to contain resinous chlorophylle, 2; bitter extractive, 8; lichen starch, 7; insoluble matters, 30; salts, &c. 3. Its virtues are dependent on the bitter and amylaceous matter, and are similar, but inferior, to those of Iceland moss. It has been esteemed as a pectoral in pulmonary affections; as an astringent in internal hemorrhages, and as a remedy for jaundice. It has been given in doses of a drachm, in the form of powder or decoction. In Siberia, where the plant seems to be more bitter than in this country, it is employed as a substitute for hops in brewing.  

10. Gyrophora.

Several species of Gyrophora (as G. proboscidea β arctica, G. hyperborea, G. Pennsylvanica, and G. Muhlenbergii) are employed by the hunters of the Arctic regions of America as articles of food, under the name of Tripe de roche. All four species were eaten by Captain Franklin and his companions in 1821, when suffering great privations in America; and to its use may their preservation be in part ascribed. But, not having the means of extracting the bitter principle, these lichens proved noxious to several of the party, producing severe bowel complaints.

11. Cladonia rangiferina, Hoffm.—Rein-Deer Moss.

Cladonia rangiferina, Hoffm.; Cenomyce rangiferina, Ach. Syn. p. 277; Lichen rangiferinus, Linn.; Reindeer Moss.—This lichen has become celebrated on account of the beautiful description of it, and of its uses, given by Linneus, in his Flora Lapponica, p. 332. It is this plant which, for the greatest part of the year, and especially during the winter season, is the support of the vast herds of rein-deer, wherein consists all the wealth of the Laplanders.

I have frequently bought this lichen, along with others, of the London herbalists, who, however, are unacquainted with its real name; but who sell various species of lichens, under the denomination of "mosses," for the use of bird stuffers, who decorate the inside of their cases with them.

---

Footnotes:
3 Franklin, Narrative of a Journey to the Shores of the Polar Sea, 1823.
12. CETRARIA ISLANDICA, Ach.—ICELAND MOSS.

Sex. Syst. Cryptogamia, Algœ.

(Planta, Offic.)

History.—The medicinal properties of this plant (usually termed Lichen islandicus) were probably first known to the natives of Iceland. According to Borrichius, the Danish apothecaries were acquainted with them in 1673. In 1688, Hjarne spoke favourably of its effects in haemoptysis and phthisis.

Botany. Gen. Char.—Thallus foliaceous, cartilagino-membranaceous, ascending and spreading, lobed and laciniated, on each side smooth and naked. Apothecia orbicular, obliquely adnate with the margin of the thallus, the lower portion being free (not united with the thallus); the disk coloured, plano-concave, with a border formed of the thallus and inflexed (Hooker).

Sp. Char.—Thallus erect, tufted, olive brown, paler on one side, laciniated, channelled, and denticulate, the fertile lacinia very broad. Apothecia brown, appressed, flat, with an elevated border (Hooker).

Hab.—Dry mountainous districts of the new and old continents. Although met with in considerable abundance in Scotland, it is never gathered there as an article of commerce.

The word cetraria is derived from cetera or caetra (xaïtrra, Hesych.), an ancient shield made of leather, which the apothecia are supposed to resemble.

Collection.—The lichen should be collected on dry and clear days, carefully deprived of all foreign matter by hand-picking, and dried in the sun.

Physical Properties.—The Iceland moss of commerce (muscus islandicus; lichen islandicus) is in general brownish or grayish white; the upper surface darker, towards the base sometimes marked with blood-red spots; the under surface paler, whitish, with white spots which have a chalky or mealy appearance, are lodged in little depressions of the thallus, and when submitted to microscopic examination appear warty, pearl-white masses. Apothecia are rather rare on the commercial lichen. When quite dry, the lichen is crisp, cartilaginous, and coriaceous. It is almost odourless, and has a bitter mucilaginous taste. Its powder (farina) is whitish gray.

Commerce.—It is imported in barrels and bags from Hamburgh and Gottenburgh, and is said to be the produce of Norway and Iceland. In 1830, 20,599 lbs. paid duty; in 1837, 12,845 lbs.; in 1838, 6179 lbs.; in 1839, 15,933 lbs.; and in 1840, 6462 lbs.

Composition.—It was analyzed by Berzelius\(^1\) in 1808, who obtained the following products from 100 parts:—green wax, 1.6; yellow extractive matter, 7.0; bitter matter, 3.0; uncrystallizable sugar, 3.6; gum, 3.7; starch, 44.6; starchy skeleton, 36.2; gallic acid, trace; bitartrate of potash, tartrate of lime, and a little phosphate of lime, 1.9 (≈101.6). In 1844–5 it was examined by Messrs. Schnedermann and Knop.\(^2\)

The following figures represent the microscopic appearances of sections of the lichens.

---

\(^1\) Ann. de Chim. xii. 277.
1. AMYLACEOUS MATTER—Cetraria islandica contains at least two kinds of amylaceous matter, namely, one which is coloured blue by iodine (lichen-starch), and one which does not become blue with this agent (inuline).

Link states that the amylaceous matter of Cetraria does not occur in a globular form. If by amylaceous matter is to be understood starch grains, which are rendered blue by iodine, my observations confirm his statement. Payen, however, says he has seen the starch of Iceland moss in the form of little balls; but he has probably mistaken the cells for starch grains. When a thin section of the thallus has been soaked in cold water and then placed under the microscope, a general blue tint is communicated to the subcortical layer (see Figs. 167 and 168), on the addition of tincture of iodine: but none of the cells or granules become blue. A starchy non-granular matter, rendered blue by iodine, appears to reside in the intercellular tissue of the subcortical layer. My friend Mr. Henry Deane has traced this amylaceous matter to the surface of the apothecium, which appears to be deficient in the cortical non-amyaceous layer. Moreover, iodine colours sections of the apothecia in stripes; rendering blue the starchy matter between the thece and elongated cells (see Fig. 169).

I have sometimes seen the nucleated cells of the medullary layer (see Fig. 168) assume an amber colour when treated with iodine. Is this owing to the presence of inuline?

a. Lichen-starch. This becomes blue on the addition of iodine. According to Schnedermann and Knopp, hydrochloric acid converts it into a transparent jelly. Its formula, according to Mulder, is C_{12}H_{10}O_{10}.

Even after very prolonged boiling in water the tissue of Iceland moss still retains the property of being tinged blue by iodine: hence it has been called amylaceous tissue, starchy skeleton, &c. Mulder says, that when boiled sufficiently and acted on by solvents, the final residue of it is nothing but celluloae: it is improper, therefore, to call it amylaceous tissue.

b. Inuline. This, according to Payen and others, is a constituent of Iceland moss. It is tinged yellow by iodine. When insoluble in cold water its formula is probably C_{12}H_{10}O_{10}.

Mulder is of opinion that the chief part of lichen-starch must be composed of a starch which like inuline is turned yellow by iodine, and like common starch can be precipitated by basic acetate of lead.

2. CETRARIC ACID; Cetrarin; bitter principle of Iceland moss.—This resides in the cortical portion of the thallus. It exists there for the most part in the state of free cetraric acid, and not as a cetrarate. In the pure state the acid occurs in the form of shining minute acellular crystals. It is intensely bitter, not volatile, and is infusible without decomposition. It is almost insoluble in water, which, however, acquires a bitter taste when boiled with the acid. It is

---

Footnotes:
soluble in boiling alcohol, but crystallizes in great part on cooling. It is slightly soluble in ether, and is quite insoluble in the fixed and volatile oils. Its formula is $C_9H_{18}O_4$. It is dissolved both by the caustic and carbonated alkalies, and is precipitated from its solution by acids. Cetrarate of ammonia ($2NH_4C_9H_{18}O_4$) is a beautiful yellow salt, having a faint ammoniacal odour, and being soluble in water. By exposure to the air it gradually becomes brown. Schnedermann explains the production of the brown colour of Iceland moss by supposing that the cetraric acid of the thallus absorbs atmospheric ammonia, and the cetrarate of ammonia thus formed becomes brown by exposure to the air. The alkaline cetrarates yield a red colour (cetrarate of iron) with the salts of the peroxide of iron. Now as the ashes of Iceland moss contain iron, Schnedermann thinks it not improbable that the red spots which are sometimes found at the base of the lichen may be due to the presence of cetrarate of iron, produced by the action of cetrarate of ammonia (formed as above explained) on the ferruginous constituent. Cetrarate of lead ($2PbO.C_9H_{18}O_4$) forms a yellow flocculent precipitate.

3. Licheneic Acid (so called from $\lambda_{\chi\varsigma\nu\zeta\sigma\varsigma}$, lichen; and $\epsilon\tau\iota\varsigma\nu\zeta$, fat). When pure it is perfectly white, and consists of pearly crystalline plates. It is odourless, but has an acid taste. It is soluble in alcohol, ether, and the volatile and fatty oils, but is insoluble in water. At 248° F. it melts, and on cooling congeals into a crystalline mass. It cannot be volatilized without decomposition. Its formula is $C_9H_{18}O_4$. It is dissolved by alkalies, and is precipitated from its alkaline solution by acids. Licheneate of potash is a white indistinctly crystalline powder: Licheneate of silver ($AgO.C_9H_{18}O_4$) is greyish white: Licheneate of lead ($PbO.C_9H_{18}O_4$) is white: Licheneate of baryta is greyish white: Licheneate of ammonia is crystallizable.

4. Fumaric Acid; Lichenic acid.—This acid was discovered in Iceland moss by Földi.

A neutral substance, called provisionally "the body C," is mentioned by Schnedermann as being contained in tolerable quantity in the lichen. It is white, tasteless, insoluble in water, ether, oils, alkalies, and acids, and difficultly soluble in hot spirit.

Chlorothalle; Thallochlor. This is the green colouring matter. It is soluble in ether, alcohol, and petroleum. It has the properties of a weak acid, and is distinguished from chlorophyll by being little or not at all soluble in hydrochloric acid.

Chemical Characteristics. Iceland moss swells up in cold water, to which it communicates some portion of bitterness, and a very little mucilage. If to the moistened thallus some tincture of iodine be added, the tissues become intensely blackish blue; but the white chalky or mealy-looking spots, before mentioned, are unaltered by iodine, and appear more brilliantly white, in consequence of the black ground on which they are placed.

By prolonged boiling in water, the lichen yields a mucilaginous decoction, which, when sufficiently concentrated, gelatinizes on cooling. A solution of iodine communicates a blue colour (iodide of starch) to the cold decoction.

When the decoction has been imperfectly prepared in consequence of being weak, and in insufficiently boiled, it yields a dingy green colour with iodine. The green colour depends on the mixture of two coloured substances: one yellow, the other blue. "Il," says Mulder, "a diluted decoction of Iceland moss, after being coloured with iodine, is allowed to settle for a while, the layer at the bottom is yellow, and that immediately above is blue."

The decoction yields, with the basic acetate of lead, a copious whitish precipitate (amyllate of lead); and with a mixture of sulphate of copper and potash, a green precipitate (cetrarate of copper).

The sesquisalts of iron communicate a red colour (cetrarate of iron), both to the decoction and to an alcoholic tincture of Iceland moss (prepared by digesting $3ij$ of the lichen in $f\tilde{z}yj$ of rectified spirit).

In strong hydrochloric acid the thallus swells up, owing to the gelatinization of the starch contained in the intercellular spaces.

Physiological Effects. a. On animals. In Carniola, pigs, horses, and oxen are fattened by it.

b. On Man. It is a mucilaginous or demulcent tonic, without any trace of astrigency. If the bitter matter (cetraric acid) and extractive be removed, it is nutritious, emollient, and demulcent, like ordinary starch, over which it has no advantage. Captain Sir John Franklin and his companions tried it as an article of food, when suffering great privations in America, but its bitterness rendered it hardly eatable.

1 Herberger, Journ. de Pharm. xxii.
3 Narrative of a Journey to the Shores of the Polar Sea, p. 414, 1823.
Uses.—Iceland moss is well adapted to those cases requiring a nutritious and easily-digested aliment, and a mild tonic not liable to disorder the stomach. It has been principally recommended in chronic affections of the pulmonary and digestive organs, particularly phthisis, chronic catarrh, dyspepsia, chronic diarrhoea, and dysentery; but its efficacy has been much exaggerated.

Administration.—It is best exhibited in the form of decoction. When employed as an alimentary substance merely, the bitter matter should be extracted before ebullition. This is effected by digesting the lichen in a cold weak alkaline solution (composed of water 300 parts, and carbonate of potash 1 part), and afterwards washing it with cold water.¹ But the subsequent washing will not remove the whole of the alkaline salt. Instead, therefore, of using an alkali, distilled water may be used to extract the bitter principle. The lichen should be heated once or twice in water up to about 180° F., by which the lichen will be deprived of most of its bitterness. It is then to be boiled in water or milk. When the decoction is sufficiently concentrated it gelatinizes on cooling. It may be flavoured with sugar, lemon peel, white wine, or aromatics, and then forms a very agreeable kind of diet.

DECOCTUM CETRARLE, L. [U. S.]; Decoction of Lichenis Islandica, D.; Decoction of Iceland Moss. (Iceland Moss 3v [3j], D. (58s, U. S.); Distilled Water [Water, U. S.] 170; boil down to a pint, and strain.) Dose, 10 to 15 of 3v every four hours.

13. Parmelia parietina, Aeh.—Common Yellow Wall Lichen.

PARAMELIA PARIEITINA, Aeh.; Lobaria parietina, Hoffm.; Lichen parietinus, Linn.; Common Yellow Wall Lichen. Usually sold in the herb shops under the name of common yellow wall moss. Xiphoz phylol, hodie in Zacyntho, Sibth. Thallus foliaceous, membranaceous, orbicular, bright-yellow: the lobes marginal, radiating, rounded, crenate, and crisped, granulated in the centre, beneath paler and fibrillose. Apothecia deep-orange, conceve with an entire border (Hooker). This lichen has been the subject of repeated chemical investigation. According to Herberger,² it contains two beautiful colouring matters (parmelia-yellow and parmelia-red), several alimentary principles (gladiin, sugar, starch, and gum), and three medicinal substances (soft resin, bitter matter, and volatile oil); besides wax, stearine, chlorophyll, and woody fibre. Hochleider and Heide³ give the name of chrysophanic acid (C₈H₉O₃) to the golden yellow crystallizable colouring matter, which, more recently, Schlossberger and Depping⁴ have found to be identical with the yellow colouring matter of rhubarb (rheum, rheumina, rhabarbaric acid). In 1815, this lichen was lauded by Dr. Sander⁵ as a valuable substitute for cinchona bark in intermittents. He also gave it with success in hemorrages and fluxes. Haller had previously spoken favourably of it as a tonic in diarrhoea and dysentery; and Willemot had found it useful in conusious intestinal fluxes. Subsequent experience, however, has not confirmed the favourable reports made of its medicinal power. The dose of it in powder is from 3j to 3j. It may also be given in the form of decoction, tincture, and extract. Dr. R. D. Thomson⁶ has proposed it as a test for alkalis, which communicate to its yellow colouring matter (called by him parietin) a beautiful red tint.

2. Lichenes tinctorii.—Tinctorial Lichens.

1. Number and Variety.—A considerable number of lichens have been employed by man on account of the colouring matter which they yield him. Some of them (e. g., Parmelia parietina and Evernia vulpina) contain colouring principles (e. g., chrysophanic and vulpinic acids). Others (e. g., several species of Roccella, of Lecanoria, &c.) contain principles (e. g., orsellin, erythrin, lecanoric, and gyrophoric acids) which are colourless while in the plant, but

¹ Dr. Davison, in a paper On the Removal of the bitter taste and lichenous odor of Iceland Moss (Jameson’s Edinb. New Phil. Journ. vol. xxvii, p. 966, 1840), recommends a solution of caustic potash for extracting the bitter taste of this lichen. A pound of carbonate of potash (rendered caustic by a pound of lime) is sufficient for 26 lbs. of the plant.
² Buchner’s Reprinturn, Bd. xlvii. S. 179, 1834.
⁵ Die Wundfliechte, ein Arzneimittel, welches die pers. Blinde nicht nur entbehrt macht, sondern die auch an gleicher Zeit Heilkraften übertriffet, 4to. Sondershausen, 1812.
which, under the influence of alkalies and atmospheric oxygen, yield colouring matters (e. g., orceine). Such principles I shall distinguish as colorific, or colour-making.

2. Colours.—Lichens furnish four principal colours, viz., brown, yellow, purple, and blue.

a. Brown colours are yielded by Gyrophora pustulata and Sticta pulmonaria (see ante, p. 65).

The latter lichen, says Professor Guielbort,¹ produces on silk, by using, as mordants, bitartrate of potash and chloride of tin, a very fine and durable carmelite colour. For use in France, it is principally collected in the Voges.

b. Yellow colours are yielded by Parmelia parietina (see ante, p. 69) and Evernia vulpina.

The former lichen contains, as its yellow colouring principle chrysoaphanic acid; the latter, according to M. Bébert,² contains a yellow crystallizable acid called vulpinic acid.

γ and δ. Purple and blue colours are yielded by a considerable number of lichens. In this country, purple colours (orchil and cudbear) only are obtained from them; but in Holland a blue colour (litmus) is also prepared from these. And it appears that the same lichens yield either the one or the other colour according to the method of treatment.

The orchil makers of this country call the cylindrical and flat species of Roccella used in the manufacture of orchil and cudbear, weeds or ochrella weeds, and distinguish them according to the countries yielding them (e. g., Angola weed, Canary weed, &c.); while the crustaceous and foliaceous lichens, employed for similar purposes, they term mosses (e. g., tartareous moss, pustulatus moss, rock moss, &c.). A similar distinction is made in French commerce; the term herbe being applied to what the English call a weed, while the name of lichen is given to what our dealers term a moss.

The following is a list of the principal lichens employed by British manufacturers of orchil and cudbear, with their commercial names:

Mr. Harman Visger, of Bristol, informs me that every lichen but the best orchil weed is gone or going rapidly out of use; not from deterioration of their quality, for, being allowed to grow, they are finer than ever; but because the Angola-weed is so superior in quality, and so low-priced and abundant, that the product of a very few other lichens would pay the expense of manufacture.⁴

In France, the Variolaria deilbata, De Cand., and V. orcinus or oreina, Ach. (the Parelle d’Auvergne) are employed in the production of orchil. These two lichens constitute the V. corollina, Ach., which must be confounded neither with Lecanora palla, Ach., nor with Isidium corallinum, Ach.

3. Colorific principles.—These in most, if not in all, cases are organic acids: e. g., alpha orselllic, beta orselllic, erythric, lecanoric, gyrophoric, evernic, usnic, &c. acids.

Under the united influence of water, atmospheric oxygen, and ammonia, these colorific principles yield coloured products, which, though probably not identical, pass under the general name of orceine.

The precise chemical changes which these colorific principles undergo when exposed to the joint action of water, air, and ammonia, are not definitely known. Some of these principles are not directly converted into coloured substances, but into intermediate colourless substances. Thus lecanoric acid becomes first orceine and then orceine. Liebig, adopting the formulae which have been given for these three bodies respectively by Schunck, Will, and Dumas, has given the following explanation of the changes: Lecanoric acid, C₇H₁₀O₂, gives two atoms of carbonic acid, C₂O₄, and becomes anhydrous orcin, C₆H₉O₄, which, with three atoms of water, H₂O, yields one atom of crystallized orceine, C₆H₁₁O₇; and one atom of crystallized orceine, C₇H₁₄O₅, with one atom of ammonia, NH₃, and five atoms of oxygen, yield one atom of orceine, C₇H₁₄O₇, and five atoms of water: but the accuracy of the formulae has been called in question.

¹ Hist. Nat. des Drog. simpl. t. 2me p. 77, 4me ed. 1819.
² Journ. de Pharm. t. xvii. p. 694.
³ I have not met with the Canary Rock Moss in fructification, and cannot, therefore, positively state its botanical name. I found a similar lichen in commerce under the name of British Rock Moss. The thallus of both corresponds to that of Parmelia perlata, Ach.
4. Test of the Colorific Property of Lichens.—Hellot’s test is maceration in a weak solution of ammonia (see Rocella tinctoria).

Another method is by testing an alcoholic tincture of the lichen with a solution of hypochlorite of lime. Any convenient quantity of the lichen (say one hundred grains) may be cut into very small pieces, and then macerated with milk of lime till all the coloring principle is extracted. Three or four macerations are quite sufficient for this purpose, if the lichen has been sufficiently comminuted. The clear liquors should be filtered and mixed together. A solution of bleaching powder of known strength should then be poured into the lime solution from a graduated alkali-meter. The moment the bleaching liquor comes in contact with the lime solution of the lichen, a blood red colour is produced, which disappears in a minute or two, and the liquid has only a deep yellow colour. A new quantity of the bleaching liquid should then be poured into the lime solution, and the mixture carefully stirred. This operation should be repeated so long as the addition of the hypochlorite of lime causes the production of the red colour; for this shows that the lime solution still contains unoxidized colorific principle. Towards the end of the process, the bleaching solution should be added by only a few drops at a time, the mixture being carefully stirred between each addition. We have only to note how many measures of the bleaching liquor have been required to destroy the colouring matter in the solution, to determine the amount of the colorific principle it contained. The following are the results of trials with the same test liquors upon four varieties of lichen:

Measures.

The amount of colorific principle in a lichen may also be directly determined by extracting the lichen with milk of lime, by precipitating by means of acetic acid, collecting the precipitate on a weighed filter, drying it at the ordinary temperature, and then weighing it.

5. Mode of Extracting the Colorific Principles for Transport.—Dr. Stenhouse suggests the following method: cut the lichens into small pieces, macerate them in wooden vats with milk of lime, and saturate the solution with muriatic or acetic acid. The gelatinous precipitate is then to be collected on cloths, and dried by a gentle heat. In this way almost the whole colorific matter can be easily extracted, and the dried extract transported at a small expense from the most distant inland localities, such as the Andes or Himalayas.

Dr. Stenhouse has kindly furnished me with the following table of the lichens, and their colorific principles and coloured products:

1 Phil. Trans. for 1848.
14. ROCCELLA TINCTORIA, De Cand.—DYER’S ORCHELLA
WEED.

History.—Theophrastus, Dioscorides, and Pliny, notice a plant which they respectively call πούτειον φύκος, φύκος θάλασσας, and phycos thallasion, i.e., fucus marinus. They state that it grew near the ground on the rocks of Crete, and was used for dyeing purple; and Dioscorides says that some persons imagine that the paint (fucus) used by women was this plant, but, he adds, it was a root bearing the same name.

The phycos thallasion has been usually assumed to be Roccella tinctoria, and not, as the ancients state, a sea-weed. Bory de St. Vincent even thinks that the ancients made their celebrated purple dye, brought from the isles of Elishah, with the R. tinctoria, which he therefore calls R. purpura-antiquorum.

Early in the 14th century, the art of dyeing wool with Roccella tinctoria was made known at Florence by one of the descendants of a German nobleman named Ferro or Fredigo. It is said that he accidentally discovered, in the Levant, the color obtained by the action of urine on this plant, there called respio or respo, and in Spain oregila; and that his family received the name of Oricellarii, altered to Ruellai, from this useful invention. From the latter term the generic name Roccella is supposed to be derived.

Botany. Gen. Char.—Thallus coriaceo-cartilaginos, rounded or plane, branched or laciniated. Apothecia orbicular, adnate with the thallus; the disk coloured, plano-convex, with a border at length thickened and elevated, formed of the thallus, and covering a subleptiform, black, compact, pulverulent powder concealed within the substance of the thallus (Hooker).

Sp. Char.—Thallus suffruti'cos, rounded, branched, somewhat erect, grayish-brown, bearing powdery warts [soredia]. Apothecia flat, almost black and pruinose, with a scarcely prominent border (Hooker).

β. R. tinctoria β hypomecha, Ach.; R. hypomecha, Bory. Thallus terete, filiform, very long, simplish, subconjugate, prostrate, pendulous.—Cape of Good Hope; Mauritius.—2 to 5 inches long: the thallus geniculate where the apothecia are developed (Bory): the apothecia by age lose the thalloid margin and become convex, naked, smooth, and black (Ach.).

γ. R. dichotoma, Ach., has a terete ash-gray, brownish thallus, with longish dichotomous branches.

Hab.—Maritime rocks of the eastern Atlantic islands (the Madeira isles, the Azores, the Canaries, and the Cape de Verd isles); western coast of South America (on porphyry near Riobamba in Colombia, and on the sea-shore near Chancay in Peru—Humboldt); Bourbon; extreme south of England, Guernsey, Portland Island, and the Scilly Islands.

In commerce several other species, or varieties of the same species, are met with. The most important are the following:—

R. phyropsis, Arch., is also perhaps a variety of R. fuciformis. It is intermediate in character
between the latter and R. tinctoria. Its thallus is somewhat flattened (terete-compressed), and much branched; the divisions being somewhat fastigate, rarely more than an inch long, and very furinaceous.

R. Montagnei, Belanger, Voy. aux Indes Orient. Pl. 13, Fig. 4 [no date]. Thallus coriaceous, flaccid, flat, entire and broad at the base, at length dichotomously (rarely trichotomously) laciniate, pale glaucous, sorediferous. Apothecia marginal, somewhat pedicellate, with a black convex pruinose disk, and persistent margin.—On the trunks of Mango trees (Mangifera indica) in India; especially at Pondicherry. This species, and R. pygmaea, D. R. and Mont., which grows in Algeria, are remarkable for growing on the trunks of trees; the others are found on maritime rocks.

**In 1838, 567 cwt.; in 1839, 6494 cwt.; and in 1840, 4175 cwt. of Orchella weed paid duty.**

**Physical Properties.**—Having fully described the botanical characters of the different species of Roccella, it will be unnecessary here to describe minutely the different commercial sorts.1

1 For figures of the microscopic structure of the Roccella tinctoria, the reader is referred to Link's *Icones Selectae Anatomico-Botanice*.
a. Canary Orchella Weed. *Roccella tinctoria.*—Formerly the most esteemed sort of Orchella. Thallus filiform; seldom exceeding in thickness a pin, and in length an inch and a half. Colour from pale-yellowish gray to dark brown.

b. Western Island Orchella Weed; St. Michael’s Orchella Weed. *Roccella tinctoria.*—Similar to the preceding; but less valuable as a dye-stuff.

c. Barbary Orchella Weed; Madeira Orchella Weed. *Roccella tinctoria.*—Somewhat smaller than the preceding sorts, and less valuable as a dye.

d. Lima thick Orchella Weed; South American thick Orchella Weed. *Roccella tinctoria.*—Somewhat smaller than the preceding sorts, and less valuable as a dye.

e. Cape of Good Hope Orchella Weed. *R. tinctoria b hypomecha,* Ach.—A large lichen, though rather smaller than the preceding. Remarkable for its white or gray-white appearance: many of the divisions of the thallus are geniculated. As a dye its quality is very bad.

2. Orchella Weeds have a flat (plane) or compressed thallus. These consist of *R. fuciformis,* and, perhaps, in some cases, of *R. Montagnei.*

ξ. Angola Orchella Weed. *R. fuciformis.*—Thallus very flat, seldom exceeding an inch and a half or two inches in length: in breadth (except at the fork or division) rarely more than one-sixth of an inch. Colour greenish or yellowish-gray. As a dye-stuff it is the most valuable of all the Orchella weeds.

η. Madagascan Orchella Weed. *R. fuciformis.*—Smaller, but in other respects similar to the preceding sort. Somewhat less valuable than the Angola sort.

θ. Lima thin Orchella Weed. *R. fuciformis.*—Somewhat more rounded or less flat than the preceding, which it in other respects very much resembles.

3. Mixed Orchella Weeds, consisting of both flat and round Orchella Weeds.

**Composition.**—A qualitative analysis of *Roccella tinctoria* was made by Fr. Nees v. Esenbeck, who found in it a *brown resin* (soluble in alcohol and ether, and becoming brownish red with ammonia), *wax,* *glutinous matter,* *insoluble starch,* *yellow extractive,* *yellowish-brown gummy matter,* *lichen-starch,* tartrate and oxalate of lime, and *chloride of sodium* from the adherent sea water.

The nature of the colorific principles of the Orchella weeds (*Roccella*) of commerce has been the subject of several analytical investigations; the most important of which are those of Heeren, in 1830; of Kane, in 1840; of Schunck, in 1841, and also in 1846; of Rochleider and Heldt, in 1843; of Knop, in 1844; and of Stenhous, in 1848.

Robiquet has thrown much light on the subject by his investigations into the nature of the colorific principle of *Varioaria dealbata.*

The only constituents of the Orchella weeds which will require separate notice are the colorific principles; and in describing these I shall follow Stenhous.

1. Alpha-Oselleic Acid (Stenhous); Colorific principle of Lima thick Orchella Weed (*Roccella tinctoria*).—Obtained by macerating the lichen in milk of lime, and then adding excess of hydrochloric acid to the filtered solution. A white gelatinous precipitate is obtained, which, when washed, dried, dissolved in warm alcohol, and the solution allowed to cool, yields stellate prismatic crystals of alpha-oselleic acid. It is nearly insoluble in cold water, but sparingly soluble in boiling water; pretty soluble in cold alcohol and ether, and readily so in boiling

---

1 Dr. Scouler (in Dr. Stenhous’ paper on the Lichens in the *Phil. Trans.* for 1848, p. 72) has pronounced the Angol Orchella Weed to be *R. Montagnei* of Belanger. My own examination of it led me to believe that it was *R. fuciformis.* I therefore submitted samples of it to Sir W. Hooker and Mr. Bennett, of the British Museum, both of whom have declared it to be one of the numerous varieties of *R. fuciformis.*

4 *Phil. Trans.* for 1840, p. 273.

Litmus.—History; Preparation.

alcohol. It reddens litmus, and forms crystallizable salts with the alkalies and earths. Its most characteristic reaction, by which its presence can be very readily detected, is the deep blood-red colour which it instantly strikes with a solution of hypochlorite of lime; the colour soon changes to yellow which gradually also disappears. A solution of orsellic acid in ammonia, on exposure to the air, soon assumes a bright-red colour, which gradually becomes darker and purple coloured. The rational formula for alpha orsellic acid is $C_8H_2(1O_6)^4-\cdot HO$.

2. Beta-Orsellic Acid (Stenhouse); Colorific principle of Cape of Good Hope Orchella Weed (Roccella hypomecha).—Is intermediate in its properties between alpha orsellic acid and erythric acid, but approaches the former more closely. It is crystallizable, and its solution yields a fugitive blood-red colour with hypochlorite of lime. Its ammoniacal solution also becomes red in the air. The rational formula of the hydrated acid is $C_8H_2(1O_6)^4-\cdot HO$.

3. Erythric Acid (Schunck and Stenhouse); Colorific principle of Angola and Madagascar Orchella Weeds (Roccella fusiformis).—By macerating the lichen in milk of lime, as before stated, Stenhouse obtained 12 per cent. of crude erythric acid. It is a feebler acid than alpha- and beta-or sellic acids; but it agrees with these acids in being crystallizable, and in yielding red-coloured compounds with ammonia, and also in its reaction with hypochlorite of lime. The formula of the hydrated acid is $C_8H_2(1O_6)^4-\cdot HO$.

Chemical Characteristics.—The aqueous decoction of Orchella weed forms a copious precipitate with diacetate of lead, and has its colour deepened by alkalies. Digested in a weak solution of ammonia, in a corked phial, at a heat not exceeding $130^\circ$ F., the plant yields a rich violet-red colour. This is Heliot's test for the discovery of a colorific property in lichens. By adding a solution of hypochlorite of lime to an alcoholic tincture, or to an alkaline infusion of the lichen, a fugitive blood-red colour is produced.

Physiological Effects.—Mucilaginous, emollient, and demulcent.

Uses.—In the Mauritius it is employed in decoction to alleviate cough. In Europe it is only employed as a colorific agent.

1. LACMUS.—LITMUS.

Synonyms.—Tournesol in cakes (tournesol en pains; tournesol en pierre); Dutch tournesol; lacca musica, musiva, vel musci; lacca carrulea.

History.—The manufacture of litmus was probably discovered by the Dutch about the latter end of the seventeenth century.

Preparation.—Litmus is obtained by the united influence of water, air, ammonia, and either potash or soda, on any of the tinctorial lichens capable of yielding orchil. If the potash or soda be omitted, the product is not litmus, but orchil.

The manufacture of litmus has been described by Berthollet, by an anonymous writer, by Morelot, and by Amédée Gélis. From their accounts it appears that the lichen is macerated for several weeks, with occasional agitation in a mixture of urine, lime, and potashes, in a wooden trough under shelter. A kind of fermentation takes place, and the lichen becomes first reddish, and subsequently blue. When the pulp has acquired a proper blue colour, it is placed in proper moulds, and the cakes thus procured are subsequently dried.

The moulds are either of steel or brass, and consist of two parts: the lower one divided into rectangular cells, and the upper one supporting a series of metallic rods bearing small metallic disks, so arranged as to accurately fit the cells of the lower piece.

2 Litmus is not mentioned by, and, therefore, was probably unknown to, Caspar Bauhin (Pinax, 1671), and to Dale (Pharmacologia, 3rd ed. 1737). The earliest authors in whose works I have found it mentioned are, Pomet (History of Drugs, Eng. ed. 1712), and Valentine (Hist. Simpl. 1719).
3 Neue Beiträge zur Mineralgeschichte verschiedener Länder, Bd. i. S. 370, Mietan, 1778. Berber describes the process as practiced at Amsterdam. He says that the pulp is ground in a mill, and forced through a hair cloth, before it is placed in the moulds.
4 Nicholson's Journal of Nat. Phil., Chem. and the Arts, vol. ii. p. 311, 1799. The notice of litmus is a translation from an article in the Journal du Commerce. The lichen is said to ground in a mill, and sifted through a brass wire sieve before maceration. The moulds are described as being 1 inches by 5-6ths of an inch.
6 Journal de Pharm. t. xxvii. p. 476, 1810.
The lower piece is immersed in the pulp with which they are filled, and the excess of pulp is then scraped off by means of a wooden spatula. The upper piece being then applied, the disks enter the cells, and force out the moulded cakes of litmus.

It appears from Gélis’ experiments, that any of the lichens which serve for the production of orchil may be used in the preparation of litmus.

The urine serves for the production of carbonate of ammonia, and the lime employed abstracts the carbonic acid.

The Dutch manufacturers add chalk or sulphate of lime, and some siliceous or argillaceous substance, to give body and weight to the litmus. Indigo is also introduced, doubtless for the purpose of increasing the blue colour of the cakes.

**DESCRIPTION.**—Litmus is imported from Holland, in the form of small, rectangular, light, and friable cakes of indigo-blue colour. Examined by the microscope we find spores, and portions of the epidermis and mesothallus of some species of lichen, moss leaves, sand, &c. The odour of the cakes is that of indigo and violets. The violet odour is acquired while the mixture is undergoing fermentation, and is common to all the tinctorial lichens. It has led some writers into the error of supposing that the litmus-makers use Florentine orris in the manufacture of litmus. The indigo odour depends on the presence of indigo in the litmus cakes.

**COMPOSITION.**—An accurate and complete analysis of litmus is yet a desideratum. In 1840, Dr. Kane submitted it to examination, and obtained from it four colouring principles, to which he gave the names of erythrolein, erythrolitmine, azolithmine, and spaniolitmine. These, in their natural condition, are red, and the blue of litmus, he says, is produced by combination with a base. “There are, properly speaking,” he adds, “only two characteristic colouring matters in litmus—the erythrolitmine and the azolithmine; for the erythrolein is coloured crimson purple only by alkalies, and the spaniolitmine occurs but very seldom. In the litmus of commerce these colouring substances are combined with lime, potash, and ammonia, and there is mixed up in the mass a considerable quantity of chalk and sand.”

Gélis has published some interesting observations on litmus. He says that litmus owes its colour to four different coloured products, which he designates by the letters A, B, C, and D. The ash of litmus he found to contain carbonate of potash, carbonate or sulphate of lime, alumina, silica, traces of oxide of iron, chlorine, sulphuric acid, and phosphoric acid.

I shall provisionally call the proper colouring matter of litmus derived from the lichen, _lichen-blue._

**Lichen-Blue; Litmus Blue.** By these terms I understand the peculiar blue colouring matter of litmus, which is soluble in water, and is reddened by acids. It is probably either some modification of orcin, or some allied principle. It may perhaps be a mixture or compound of several colouring principles.

It is soluble in both water and spirit, yielding a coloured solution, which, in the concentrated state, has a purple colour when viewed by transmitted light; but in the dilute state it is pure blue. Viewed by transmitted candle-light it has a reddish colour. An aqueous infusion of

---

1 Ferber saw the _Roccella_ lichen used at Amsterdam. Morelot stated that _Varioaria oricina_ yielded it. Nees and Ebermayer (Handb. d. Med. Pharm. Bot. Bd. i. S. 49); and Thomson (Org. Chemistry, p. 284), on the other hand, say that _Lecanora taracea_ is employed.—An orchil-maker, under my care in the London Hospital, told me that he had been accustomed to make litmus of pipe clay, starch, soda, and orchil liquor; and he gave me some specimens of it thus prepared. Gélis prepared it with _Roccella tinctoria_ (in the scutelliferous state), _Roccella fuseiformis_, and the mixture of _Lecanora parcella_ & _pallescens_; and _Indium corallinum_, sold under the name of _Oreille d’Auwergne_; but the last-mentioned plants yielded a less fine product than the others.

2 Phil. Trans. for 1840, p. 298.

3 Journ. de Pharmacie, t. xxvi. p. 483, 1840.
litmus neither reddens turmeric paper nor occasions a precipitate with a solution of chloride of calcium. It contains, therefore, no free alkali or alkaline carbonate.

It is reddened by acids; and also by many of the metallic salts—as corrosive sublimate, sulphate of copper, sulphate of iron, &c. The infusion of litmus, which has been reddened by acids, has its blue colour restored by alkalies, alkaline earths, the alkaline and earthy sulphures, the alkaline carbonates, the soluble borates, the tribasic phosphate of soda, the alkaline cyanides, &c.

An infusion of litmus is decolorized by chlorine and by the alkaline hypochlorites. Certain deoxidizing agents also deprive it of colour; as sulphuretted hydrogen, hydrosulphuret of ammonia, sulphurous acid, the hyposulphites, nascent hydrogen (obtained by adding hydrochloric acid and zinc to an aqueous infusion of litmus), and the protosalts of iron. If an infusion of litmus be left in contact with sulphuretted hydrogen, in a well-stopped bottle, for a few days, the liquid is decolorized, but reacquires its colour by exposure to the air or oxygen gas.

CHARACTERISTICS.—The lichen-blue is an aqueous infusion of litmus, is distinguished from other vegetable blues by the action of acids and alkalies on it (see supra); for most vegetable blues and purples (as red cabbage juice, syrup of violets, &c.) are changed to green by alkalies, whereas, lichen-blue does not undergo this change.

If a lump of moistened litmus be laid on turmeric paper, the latter is reddened by it; but by the application of heat the redness disappears.

When litmus cakes are thrown into diluted hydrochloric acid, a copious effervescence ensues, and a solution of chloride of calcium is obtained.

If a cake of litmus be ignited in the outer cone of the flame of a candle, a whitish violet tint is communicated to the flame, indicative of the presence of potash.

If the ashes of litmus be thrown into diluted hydrochloric acid, violent effervescence takes place; a solution of chloride of calcium is obtained, and a quantity of silicious sand remains undissolved.

IMPURITIES.—Inferior samples of litmus (including all those usually found in English commerce) contain indigo, the presence of which in litmus cakes is proved by their colour; by the coppery lustre which they acquire when rubbed with the nail; by digesting them in oil of vitriol, by which a blue solution of sulphate of indigo is obtained; and by heating them in a watch glass or platinum capsule, by which indigo-vapour (characterized by its well-known odour and reddish violet colour) and crystals of indigo are obtained.

USES.—Litmus is employed as a test for acids and alkalies. The former communicate a red colour to blue litmus: the latter restore the blue colour of reddened litmus. (The action of various salts on litmus has been before stated.) If the litmus present be reddened by an unboiled, but not by a boiled, water, we may infer that the acid present is a volatile one; probably carbonic acid, or perhaps sulphuretted hydrogen. Reddened litmus may have its blue colour restored not only by alkalies, &c., as before mentioned, but also by carbonate of lime dissolved in water by a considerable excess of carbonic acid.

1. TINCTURA LACMI; Tincture of Litmus. (Litmus one part; Distilled Water twenty-five parts. M.)—Though called tincture, it is in reality an infusion of litmus. In order to preserve it, a portion (about 1/4th part) of spirit may be added to it. If required to be more concentrated, the proportion of litmus should be augmented. Some persons first bruise the litmus in a mortar, and then tie it up in a linen bag before steeping it in the water. By keeping in a closely-stopped bottle, its blue colour disappears, but is shortly restored on the admission of atmospheric air.

2. CHARTA EXPLORATORIA CERULEA; Blue Test Paper; Blue Litmus Paper.—This is prepared by dipping slips of paper in a strong and clear infusion of litmus; or by brushing the infusion over the paper.

Bibulous or unsized paper is usually preferred, on account of the facility with which it imbibes the liquid to be tested; and also because the alum which frequently enters into the composition of the size affects the colour of litmus. Professor

1 See two papers by the author in the Pharmaceutical Journal, vol. ix. p. 12, 1849; and vol. x. p. 335, 1850.
Graham, however, recommends good letter paper; or, if the infusion is applied to one side only, thin and sized drawing paper. Faraday1 recommends the infusion to be prepared from an ounce of litmus and half a pint of hot water. The Prussian Pharmacopoeia of 1827 orders one part of litmus and four parts of water. Others employ one part of litmus and six parts of water.

In order to obtain extremely delicate test paper, the alkali in the litmus is to be almost neutralized by a minute portion of acid. To effect this, divide the filtered infusion of litmus into two parts; stir one portion with a glass rod which has been previously dipped into very dilute sulphuric acid, and repeat this until the liquid begins to look reddish: then add the other portion of liquid, and immerse the paper in the mixture.

Good litmus paper should be uniform in its colour, and neither very light nor very dark. When it has a purplish tint, it is a more delicate test for acids than when its colour is pure blue. When carefully dried, it may be preserved by wrapping it in stiff paper, and keeping it in well-stopped vessels in a dark cupboard or drawer.

Books of test papers, bound up like bankers' cheque-books, are sold in the shops, and are very convenient. They are about 1 3/4 inches long and 3 1/2ths of an inch wide. To preserve them they are kept in leathern cases.

Blue litmus paper is used to detect the presence of acids and of certain salts which react as acids.

3. CHARTA EXPLORATORIA RUBEFACTA; Reddened Test Paper; Red Litmus Paper. This is prepared with an infusion of litmus which has been slightly reddened by an acid. Blue litmus paper may be extemporaneously reddened by exposing it for a few seconds to the vapour of acetic acid; but for preserving, it is better to prepare the paper with litmus which has been reddened by a minute portion of dilute sulphuric acid: the acetic acid being objectionable, on account of its volatility.

Red litmus paper is employed as a test for alkalis and certain salts (see supra), which react as bases.

2. ORCHILLA.—ORCHIL-LIQUOR.

Two kinds of liquid or thin pulp called Orchil or Archil are met with: one termed blue orchil, the other red orchil. They are prepared as follows: blue orchil is procured by steeping the lichens before mentioned (see pp. 70 and 71) in an ammoniacal liquor in a covered wooden vessel. Red orchil is made with the same liquor in common earthen jars placed in a room heated by steam, and called a stove. In one manufactory which I inspected, the ammoniacal liquor was prepared by distillation from a mixture of lime, impure muriate or sulphate of ammonia obtained from gas-works, and water; but some makers still employ stale urine and lime. Both kinds of Orchil sold in the shops are liquids of a deep reddish purple colour and an ammoniacal smell. Red and blue orchils differ merely in the degree of their red tint.

According to Dr. Kane, Orchil consists of orcein, erythroleic acid, and azo-erythrine. To these must be added ammonia.

Orchil is employed merely as a colouring agent. It is used for dyeing, colouring, and staining. It is sometimes used as a test for acids.

3. CUDBEAR.

Cudbear is called by the Germans Persio.4 The manufacture of this pigment was begun at Leith about the year 1777, by the late Mr. Macintosh of Glasgow, under the management of Dr. Cuthbert Gordon. From the latter gentleman's name the term cudbear (at first Cuthbert) originated.

1 Chemical Manipulation.
2 The word persio is probably derived from persica, on account of the resemblance of the colour of cudbear to that of a peach.
It is procured in the manner of Orchil, by the mutual action of some of the colorific lichens, air, and an ammoniacal liquor. White Scotch or tartaraceous moss (Lecanora tartarea) was formerly chiefly used in its manufacture. When the proper purplish red colour has been developed, the mixture is dried in the air and reduced to powder.

I have found in the shops two kinds of powder of cudbear, one called red cudbear, the other blue cudbear. Both are purplish red—but one is redder than the other. I have likewise met with red and blue cudbear pastes: but the term Orchil might with more propriety apply to these.

Cudbear is employed as a purple dye for woollen yarn; but the colour which it yields is fugitive. It is sometimes used for colouring pharmaceutical preparations; and it may be employed also as a test.

Cudbear paper is sometimes used as a test for acids and alkalies. "A paper prepared from an infusion of the best cudbear, without the addition of either alkali or acid, has a purple colour, and is affected by both acids and alkalies. It is convenient in alkalimetry, being already too red to be sensibly affected by carbonic acid, while it is distinctly reddened by the mineral acids."  

**Order III. Fungi, Juss.—Fungals.**

**Fungaceae, Lind.**

Characters.—Plants consisting of a congeries of cells or filaments, or both variously combined, increasing in size in the more perfect species by addition to their inside, their outside undergoing no change after its first formation; chiefly growing upon decayed organic substances, or soil arising from their decomposition, frequently ephemeral, and variously coloured, never accompanied, as in Lichens, by reproductive germs of a vegetable green called gonidia; nourished by juices derived from the matrix. Fruktification either spores attached externally, and often in definite numbers, to the cellular tissue, and frequently on peculiar cells called sporo-phores or basidia, which are in many cases surmounted by fine processes which immediately support the spores, and called spicules or sterrignata; or inclosed in membranous sacs or asci, and then termed sporidia (Berkeley, in Lindley's Vegetable Kingdom).

Properties.—Variable: we have esculent, medicinal, and poisonous species; and unfortunately there are no anatomical characters by which the poisonous are to be distinguished from the edible fungi.

They are remarkable for containing a very large proportion of water; and for their dry matter being rich in nitrogen and phosphates. Among their proximate constituents are several alimentary principles (e. g. albumen, sugar, mannite, and mucilage), and some poisonous ones (ergotin, tremellin, and amanitin). The substance called fungin, formerly considered to be a nutritive principle, appears to agree with cellulose in its nature.

**Sub-order I. Gymnomycetes, Endl.**

**Coniomycetes, Fries.**

Characters.—Sporidia naked (without any hymenium, peritheciun, asci, or sporidiferous flocci), produced beneath the epidermis of plants or within the matrix (Fries).

Properties.—No medicinal substances are obtained from this sub-order. The yeast plant, which Turpin refers to the genus Torula (from torus, a twisted cord), is more probably an imperfect mucedinous fungus, and as such will be noticed hereafter (see sub-order Hyphomycetes). The ergot-mould, called, by the late Mr. E. J. Quckett, Ergotasia abortifaciens, and referred to this sub-order, is considered by Link and some other authorities to be a species of Oidium, and as such will be noticed subsequently (see sub-order Hyphomycetes).

---

1 Graham, Elements of Chemistry, p. 923.
Sub-order II. Hyphomycetes, Fries.

Characters.—Flechi sporiferous, naked (Fries).

Properties.—To this sub-order (which is closely allied to Coniferaceae, p. 51.) are referred the yeast plant, the ergot-mould, mother of vinegar, and some other plants interesting alike to the physician and pharmacist.

15. FERMENTUM CERVISIE.—BARM or YEAST.

(Cervisie: Fermentum, L. D.)

History.—Leaven and ferment have been known from the most remote periods. Leaven (or sour dough), called in Hebrew seor, and ferment, termed in Hebrew khametz, are both referred to in the Old Testament: the one applies to solids, the other to both solids and liquids. In the common version, however, both these Hebrew words are translated leaven. The Greeks appear to have used the term ἔνυρσα in a general sense, to include both leaven and ferment. Dioscorides speaks of the medical properties of the leaven of wheat (ἀτσεμαν, ῆνυρσα), which Galen and Paulus simply call ἔνυρσα. Pliny distinguishes leaven (fermentum) from beer yeast (spuma cervisia).

The history of the discovery of the vegetable nature of yeast is an interesting subject of inquiry. So long since as the year 1680, Leeuwenhoek described and figured the globules of beer-yeast. He was fully aware of its vegetable nature, but was ignorant of its power of vegetating or growing, and notwithstanding the high magnifying power which he used, he failed to detect the presence of the granules or nuclei in the interior of the yeast-cells.

In 1826, Desmazières published some observations on Persoon's genus Mycoderma, which he defined anew, and referred to Gaillon's class of infusory animals, called Nemazoaria (now placed among Algae). He described a Mycoderma vini, glutinis farinulae, multi-junterperi, multi-cervisie, and cervisie. The latter is frequently considered to be the yeast-plant; but Desmazières confounded two things which deserve to be considered entirely distinct, namely, the yeast-plant, properly so called (the Torula Cervisie of Turpin), and a larger filamentous confervoid plant, to which more strictly the name of Mycoderma Cervisie of Desmazières should be confined.

To Cagniard-Latour is due the credit of establishing the real nature of yeast. During the years 1835 and 1836, he communicated to the Société Philomathique some researches on ferments, which were published in the journal called l'Institut (Nos. 158, 159, 164, 165, 166, 167, 185, and 199); and on the 12th of June, 1837, he presented to the Academy of Sciences his Mémoire sur le Fermentation Vinicuse, a notice of which appeared in the Comptes Rendus of that period. The report on this memoir, drawn up by Turpin, in the name of himself, Thenard, and Becquerel, was made to the Academy in July, 1838 (Comptes Rendus); and the memoir itself was printed in the 68th volume of the Annales de Chimie et de Physique, 1838.

About the same time, Schwann was occupied in investigations on this sub-
BARM OR YEAST.—BOTANY. 81

ject, but his observations were not published until 1837. He denied that the organized being found in fermenting liquids is one of the infusoria, as Desmazières had supposed, but asserted that it is undoubtedly a plant, and that it has great resemblance to many jointed fungi. Meyen, who examined it at Schwann's request, agreed as to its vegetable nature, and considered that the only doubt which could exist respecting it was, whether it was an algal or a fungus, but its deficiency in green pigment led him to regard it as a fungus. The filamentous fungus found in saccharine solutions which are undergoing fermentation, Schwann, therefore, proposed to call the sugar-fungus (Zuckerpilz). Meyen adopt Schwann's proposal, and refers to three species of Saccharomyces, viz., S. vini, S. cerevisiae, and S. pomorum.

In 1837, Kützing described and figured the yeast-plant.

On the 20th of August, 1838, Turpin read to the Academy of Sciences at Paris, his valuable Mémoire sur la Cause et les Effets de la Fermentation Alcoolique et Aceetique.

The notion that yeast was an organized being, in fact a living plant, was at first strongly opposed by Berzelius and Liebig; but was soon adopted by the eminent chemist Mitscherlich. 8

BOTANY.—The substance called yeast is a mass of microscopic cryptogams.

The organization and vitality of yeast are demonstrated by the form and structure of its particles, as determined by the microscope; by their chemical composition; by their reproductive power, as proved by the generation of yeast during the fermentation of beer; and lastly, by the effects of mechanical injuries, of heat and cold, and of chemical and other poisons.

Kützing, who is a believer in the convertibility of some of the lower algas into species, or even genera, of a higher organization, is of opinion that yeast is an algal in its lowest, but a fungus in its highest, grade of development.

It is more probable, however, that this plant is a fungus in all stages of its existence; and that what we know as yeast is either a mass of sporidia or the separated joints of the spawn or mycelium of a fungus whose more perfect state is at present undetermined, but which is probably a mucidinous fungus, perhaps allied to Penicillium. In the present state of uncertainty, I have thought it preferable to desig-

2 Journal für praktische Chemie, Bd. xi.
3 Mémoire de l'Académie Royale des Sciences, t. xvii. 1840.
4 In Liebig's Annalen der Physik u. Chemie, vii. p. 100, b. 20, a satirical paper (The Mystery of Vicous Fermentation unfolded) was published, representing yeast to be an insidious animal which fed on sugar, and evacuated by the alimentary canal spirit of wine, by the urinary organs carbonic acid! In his Chemistry, and its Application to Agriculture and Physiology, edited by Dr. Playfair, 2d edition, 1832, Liebig declares yeast to be a body in a state of decomposition, and states that the identity of the living itself as seeds reproduce seeds, cannot for a moment be entertained. But in the third edition of his Animal Chemistry (edited by Dr. Gregory, 1846) he does not attempt to deny the vegetable nature of yeast, though he thinks that investigation into the nature of this substance is not yet completed.
6 A very curious fact was mentioned to me by the importer of German and Dutch yeast, in Finch-lane, Cornhill, London: it is, that mechanical injury kills or destroys yeast. Foreign yeast is imported in bags, and of these great care is requisite in their removal from place to place. If they be allowed to fall violently on the ground, the yeast is spoiled. A bruise, as a blow given to the bag, also destroys it. The men who make up the dried yeast into quarter-pound and half-pound balls for sale, are obliged to handle it very dexterously, or they injure and destroy it. In fact, falls, bruises, or rough handling, kill it, and the yeast which has thus been mechanically injured may be readily distinguished from good, unaltered yeast. Its colour becomes darker, somewhat like the change which an apple or pear undergoes when it becomes rotten; and, from being cavernous or powdery, it becomes soft, glutinous, sticky to the fingers like flour-paste, and soon stinks. I have submitted some of this injured or dead yeast to microscopical examination, but have been unable to detect any difference in its appearance from healthy yeast. The effect of mechanical injuries is also noticed by several writers. Thus Liebig (Chemistry in its application to Agriculture, by Dr. Playfair, p. 266, 3d ed. 1842) remarks that simple pressure diminishes the power of yeast to excite vicinal fermentation.
7 Boiling for a short period injures, and for a long period destroys, the power of yeast to excite fermentation. (Berzelius.) Gold interrupts fermentative action apparently by rendering the yeast-plant torpid.
8 The power of yeast to excite vicarious fermentation is arrested or destroyed by alcohol, acids, alkalies, various salts (chloride of sodium, bichloride of mercury, nitrate of silver, & c.), volatile oils, excess of sugar, &c. (See Berzelius and Liebig; also, Queneuens, in the Journal de Pharmacie, t. xiv. p. 533, 1838.)
9 The following are, according to Kützing, the generic and specific characters of the Yeast-plant, which he called Cryptococcus Fermentum, and refers to Mycophytae (Filletzanne), a sub-order of Algae. C. Fermentum.—Submersed: globules elliptical, solid, in the centre 1 or 2-punctate.

VOL. II.—6
nate it by its more classical name (*Fermentum Cervisae*) than to adopt any of the following botanical names, which have been given to it: *Mycoderma Cervisae*, Desmazières; *Torula Cervisae*, Turpin; *Cryptococcus Fermentum*, Kützing; *Saccharomyces Vini et Cervisae*, Schwann and Meyen. For while *Mycoderma* is a spurious genus (Fries and the Rev. M. J. Berkeley), the yeast-plant has been declared, by an eminent fungologist, to be certainly no Torula; and as Kützing’s notion of its algaceous nature is not admitted by botanists, his name of *Cryptococcus Fermentum* is scarcely admissible for it.

The Yeast-Plant.

i. Lateral branches composed of two joints.

l. An individual whose cell had evolved two branches.

The more or less small intermixed cells or granules are probably abortive.

When submitted to microscopic examination, yeast is found to consist of globose, or more or less ovoidal, ellipsoidal, or somewhat pyriform, transparent, nucleated cells, varying in size from \( \frac{1}{720} \) th to about \( \frac{1}{50} \) th of an English inch. The nucleus appears to me to consist of a mass of granules or nucleoli of unequal size: some of the larger ones are highly refractive, and probably contain oily or fatty matter. The nucleoli are called by Turpin, *globuline*.

Turpin spent a night in a brewery to examine the changes which the yeast under-
goes during the fermentation of beer. The fresh yeast had the appearance indicated in Fig. 176. In one hour after it had been added to the wort, he says that germination had commenced; the maternal cells had produced one or two buds or young cells (see Fig. 177). In three hours many of the cells were didymous, or double, the buds having attained the size of the maternal cells, and some of them had themselves begun to produce other buds or young cells (see Fig. 178). In eight hours the cells were arranged in rows, forming moniliform mucilaginous plants, composed of several cells or joints, which varied somewhat in diameter and shape. Terminal, and in some cases lateral, buds or young cells were observed, showing that the plants were about to ramify. Some of the smaller rows were seen to explode and emit a fine powder, consisting of minuter globules (see Fig. 179). Turpin placed some yeast-cells in an aqueous solution of sugar, and in three days observed that jointed filaments, with lateral branches, were produced (see Fig. 180).

I have myself examined yeast at Messrs. Hanbury and Buxton's brewery at various stages of the fermentation of both porter and ale, from a few hours to many days. In the more advanced stages of fermentation, I observed the globules of yeast were frequent in strings, or rows, apparently forming moniliform often branched plants. But as the cells or joints were very readily separable, I could not satisfy myself that the adhesion was otherwise than mechanical, such as we see between the blood-disks when they arrange themselves in series like money-rolls, and such as we sometimes perceive even in inorganic amorphous precipitates. My experience agrees precisely with that of Schlossberger, who states that he 'never could perceive a budding or bursting of the yeast-cells, accompanied by a discharge of their contents, nor could I ever produce this by compression. These curious brachial and other adjustments of the cells of yeast to each other, appeared to me the work of chance.' It is, however, proper to add, that the artificial rupture of the cells has been effected by Mitscherlich, who also confirms Turpin's observation of the budding of the yeast-cells (see p. 84).

**Origin.**—It is well known that a pure solution of sugar will not undergo fermentation when exposed to the air, but a saccharine vegetable juice, which contains albuminous matter (as the juice of the grape), suffers spontaneous fermentation, and this process always begins with the formation of yeast-cells.

By some it is assumed that these arise from yeast-germs floating in the air, and which, meeting with a fit receptacle for their development in the vegetable juice, germinate and grow, and effect vinous fermentation. By others their production is ascribed to a *generatio primitiva*.

Turpin was of opinion that there are three sources or modes of production of the yeast-plant: 1st, the transformation of globuline into yeast-cells; 2dly, budding, or the separation of the joints of moniliform stems; 3dly, the escape of spores (*globulins seminulifères*) from the interior of the cells: Mitscherlich admits the two latter modes of growth.

The amylaceous particles contained in the cells of the albumen of barley (see Figs. 181, 182) are called by Turpin *globuline*. The transformation of these into yeast-cells is, according to the same authority, the primitive origin of beer yeast. Dr. Lindley

---

2 *Introduction to Botany*, p. 113, 4th ed. 1848.
partly confirms Turpin, for he states that he has seen these smaller granules sprout during fermentation; and he adds, that they have at that time lost all their starch, for iodine produces no sensible effect upon their colour.

Turpin states that 35 lbs. of dried or pressed yeast produced during the brewing of 5700 litres [about 14 butts] of beer 247 lbs. of dried or pressed yeast: that is, an actual increase of 212 lbs. of new yeast.

In the deposit from the porter refrigerator of Messrs. Truman and Hanbury's brewery, I have observed the forms deposited in Fig. 183, c, d, e, and f. These constitute the plant called by Desmazières the Mycoderma Cervisia.

**Occurrence in the Human Body.**—Yeast-cells have been found in the human body. Hannover detected them in the black coating of the tongue of a typhoid patient. They have also been discovered in the liquids of the oesophagus, stomach, and intestine. In some cases, probably, they may have been introduced by the beer drank by the patient; but, in other cases, their presence could not be accounted for in this way. As they are developed in the urine of diabetic patients, their occurrence in urine has been supposed to indicate the existence of sugar, but they have been found also in non-saccharine urine.

**Description.**—In commerce, three varieties of yeast are known and distinguished. These are, brewers' yeast, dried yeast, and patent yeast.

1. *Brewers' yeast.*—In breweries, two kinds of yeast may be distinguished, namely, upper or top yeast, and lower or bottom yeast. These have been described by Mitscherlich.¹

Top yeast consists of large cells, at the extremities of which small ones are developed. It appears, therefore, to be produced by buds. In Berlin, the most beautiful top yeast is obtained at a temperature of 77° F.

Bottom yeast consists of cells of various sizes, without any small globules attached to the large ones. It appears to be produced by the growth of small isolated granules (spores?), which Mitscherlich thinks have escaped from the yeast-cells which have burst and disburthened themselves of their contents. Bottom yeast is multiplied at a lower temperature than top yeast: Mitscherlich says, that the bottom ferment of Bavarian beer is produced at a temperature which must not exceed 48° F. nor go below 32° F. The bottom yeast sold at breweries is generally impure.

Brewers and bakers distinguish yeast according to the quality of the beer from which it is obtained. *Ale yeast* is the best and strongest; and is used for bread-making. *Porter yeast* is objected to by bakers, but is used in distilleries. *Small-beer yeast* is said to be weak, but rapid in its effects, and is sometimes used in making rolls.

2. *Dried yeast.*—Under this name is sold a granular or pasty mass of yeast-cells, which have been separated from mechanically admixed solids, as well as from the supernatant fermented liquid, probably by filtration through linen cloths and sub-sidence. That which is sold in London is imported from Holland, Belgium, and Germany, and is commonly called German yeast. It comes over in hempen bags,

---

each holding half a hundred weight. If transported in casks it is apt to burst them, unless they are strongly iron-bound, by the quantity of carbo nic acid which it evolves.

3. Patent yeast.—This might with more propriety be called artificial yeast. It is a watery liquid, containing yeast-cells, and which has usually been prepared purposely by the fermentation of an infusion of malt and hops. The hops probably contribute to prevent the liquid becoming rapidly sour. Turpin thinks that their oil may act as a stimulant in the development of the yeast-plant. I am informed by a baker that he prepares patent yeast for bread-making by mashing half a peck of ground malt with six gallons of water at 170° F.; then boiling the wort with half a pound of hops; and to the cooled liquid adding some brewers' yeast. In 24 hours the patent yeast is fit for use. It rapidly turns sour in warm weather; and I am informed that bread made with it does not keep so well as that prepared with other kinds of yeast. It is in general use among bakers, especially those who use an inferior kind of flour.

Mr. Fowkes describes the following mode by which he prepared some artificial yeast: "A small handful of ordinary wheat-flour was made into a thick paste with cold water, covered with paper, and left for seven days on the mantle-shelf of a room where a fire was kept all day, being occasionally stirred. At the end of that period three quarts of malt were washed with about two gallons of water, the infusion boiled with some hops, and when sufficiently cooled, the ferment added. The results of the experiment were a quantity of beer (not very strong, it is true, but quite free from any unpleasant taste), and at least a pint of thick barn, which proved perfectly good for making bread."

COMPOSITION.—Yeast has been analyzed by Maret, Dumas, by Mitscherlich, by Mulder, and by Schlossberger.

It consists of two parts, the cell-walls, composed of a kind of cellulose, and the contents of the cells, composed of a protein substance, and probably fat, or oil.

1. Cell-walls.—By digesting yeast in a weak solution of potash, the contents of the cells are removed, and the membranous matter composing the cell-walls is left. In its composition it approximates to cellulose or starch.

2. Contents of the Cells.—According to both Mulder and Schlossberger, yeast-cells contain a substance allied to the protein bodies.

Besides traces of phosphorus and sulphur, Mulder regards the contents of the cells as being the hydrated oxide of protein, $\text{C}_9\text{H}_7\text{N}_4\text{O}_{36} = \text{C}_9\text{H}_8\text{N}_4\text{O}_{36} \cdot \text{H}_2\text{O}$. 

---

4 Various receipts for making yeast are given in Webster's Encyclopaedia of Domestic Economy, p. 700.
7 Traité de Chimie appliquée aux Arts, l. vi. p. 316, 1843.
9 The Chemistry of Vegetable and Animal Physiology, translated by Dr. Fromberg, p. 48; also, Pharm. Central Blatt für 1844, S. 891.
It is probable that, besides a proteine body, the cells contain a fatty, or oily substance. Schlossberger states that he extracted a yellow oil from yeast by means of ether.

3. Ashes.—According to Schlossberger, the ashes of upper yeast amounted to 2.5; of lower yeast, to 3.5 per cent.

Physiological Effects.—The effects of yeast on the animal economy are, if at all, not very obvious. The constituent of the cell-walls is insoluble, and therefore inert. The contents of the cells may, perhaps, be slightly nutritive. To the evolved carbonic acid have been ascribed the topical antiseptic effects of yeast.

The tonic and laxative effects ascribed to beer yeast, are probably referable to the fermented malt liquor in which the yeast-cells are usually contained and exhibited (see Wort).

Uses.—Yeast is employed both for medicinal and chemical purposes.

As a medicine, yeast has been used both internally and externally. Internally, it has been administered as a tonic and antiseptic in typhoid fevers. Dr. Stoker states, that it usually acts as a mild laxative, improves the condition of the alvine evacuations, and is more effectual in removing petechiae and black tongue than any other remedy. It is admissible where cinchona and wine cannot be employed, on account of the inflammatory symptoms. The dose of it is two tablespoonfuls every third hour, with an equal quantity of camphor mixture. Enemata of yeast and assafoetida are said, by the same writer, to be efficacious against typhoid tympany.

Externally, it has been used in the form of poultice. (See Cataplasma Fermenti.) Yeast is an important agent in panification and brewing. In some cases of dyspepsia, unfermented bread appears to agree better with the stomach than fermented bread, which is supposed to derive an injurious quality from the yeast used in its preparation.

Yeast is sometimes added to liquids to excite the vinous fermentation, and thereby to detect the presence of saccharine matter.

L. Gmelin employed this test to detect sugar in the animal fluids after the ingestion of amylaceous food. Dr. Christie found it so delicate, that he could detect with it one part of sugar in 1000 parts of healthy urine of the sp. gr. 1.030. Messrs. Richard Phillips, Graham, and George Phillips used it to detect the presence of saccharine matter in tobacco adulterated with this substance. (For the mode of using this test, see Saccharum.)

1. CATAPLASMA FERMENTI, L.; Cataplasma Fermenti Cerevisiae; Yeast Poultice.—(Yeast, Water heated to 100° F., of each f 3 f; Flour lb j. Mix the yeast with the water, and add the flour, stirring so that a poultice may be made. Place it before the fire until it swells up.)—It is applied, when cold, to fetid and sloughing sores as an antiseptic and stimulant: it destroys the fetor, often checks the sloughing, and assists the separation of the dead part. It should be renewed twice or thrice a day. I have frequently heard patients complain of the great pain it causes. The carbonic acid is supposed to be the active ingredient.

The following poultices are analogous in their nature and effects:—

2. CATAPLASMA FÆCULEC CERESVISE, Guy’s Hospital Ph.; Poultice of the grounds of beer.—(Grounds of beer; Oatmeal; as much of each as may be required to make a poultice.)—It is applied cold twice or thrice a day, in the same cases as the preceding preparation, to which its effects are analogous.

This poultice was formerly called the discutient cataplasm or cataplasma discutiens, and was applied to disperse tumours.

3. CATAPLASMA BYNES, Guy’s Hospital Ph.; Malt-meal and Yeast Poultice; Malt Poultice.—(Malt-meal and Beer yeast; as much of each as may be required to make a poultice.)—This poultice is to be applied warm.
16. OIDIUM ABORTIFICIENS.—THE ERGOT-MOULD.

**History.**—Phillipar,¹ in 1837, recognized the joints or sporidia of this fungus on ergot. Phoebus,² in 1838, detected and figured these bodies, but did not consider them to be of a fungic nature. Mr. John Smith,³ of the Kew Garden, in November, 1838, recognized them on various ergotized grasses. He considered them to be the joints of a minute articulated fungus, from whose action ergot resulted. In December, 1838, the late Mr. E. J. Quekett⁴ gave an extended account of this fungus, in a paper read before the Linnean Society. Mr. Quekett named the plant *Ergotaetia abortans* (*Eryotaeidia* from *Eryot*, and *aria*, origin; *abortans*, in allusion to its destroying the germinating power of the grain of grasses, and also to the medicinal powers of ergot). Subsequently, at my suggestion, he substituted the word *abortificiens* for *abortans*.

Mr. Quekett at first⁵ considered this fungus to belong to the sub-order *Hyphomyctes*, tribe *Mucedines*; but after his paper had been read at the Linnean Society, and was returned to him for correction, he was led to suppose that the fungus belonged to the sub-order *Coniomycetes*, tribe *Sporidesmiæ*, because its sporidia were produced beneath the epidermis of the grain. Both Link⁶ and the Rev. M. J. Berkeley consider the ergot-mould to be a mucedinous fungus belonging to the genus *Oidium* (so called from οίῳ, an egg, and ἱδῆς, resemblance), and I have, therefore, called it, at the suggestion of the last-named eminent fungologist, *Oidium abortificiens*. Corda⁷ has recently referred it to the genus *Hymenula*, of the sub-order *Hymenophyctes*, and names it *Hymenula Clavus*.

**Botany.** **Gen. Char.**—Microscopic. *Threads* white or brightly coloured, simple or irregularly branched, moniliform above, and breaking up into more or less elliptical spores. (Berkeley in Lindl. *Med. and Econ. Bot.*, p. 14, 1844.)

---

**Fig. 184.**

**D**, Membrane of sporidium laid open.

---

⁶ *Beitrag zur Kenntniss der Brandarten der Gerste und des Mutterkorns*, in the *Oekonomische Neuglieder und Verhandlungen*, No. 83, 1846: a periodical publication. I am indebted to the Rev. M. J. Berkeley for the loan of Corda’s paper. A copy of Corda’s figures, illustrating the structure of the ergot of rye, and of the microscopic appearance of the fungus, will be given hereafter (see *Secale Cereale*).

Sp. Char.—Threads white, irregularly branched; spores abundant, elliptic, containing two nuclei (Berkeley).

Mr. Quckett's description of the ergot-mould (called by him Ergotetia abort-ificiens) is as follows: Sporidia elliptical, moniliform, finally separating, transparent, sometimes slightly contracted about their middle, usually containing one, two, or three, but occasionally as many as ten or twelve well-defined greenish granules. They are, on the average, about 1-4000th of an inch long, and 1-6000th of an inch broad. When placed on glass and moistened with water, they readily germinate or produce other plants, though in various ways, as sometimes by emitting tubes (B), by the development of buds (c), and by the formation of septa across their interior (E, F, G, H).

Hab.—Floral envelopes, and ovaria of grasses: Europe, America.

By the growth of these fungi upon or within the ovarium of grasses, a diseased condition of the ovarium, involving the whole of the embryo, and sometimes partially or wholly the albumen, is produced. This disease, called the ergot or spur, will be described hereafter (see Secale Cornutum). Mr. Quckett has shown that the sporidia of this fungus are capable of infecting healthy grains of corn, and of ergotizing them.

Properties.—The chemical properties and physiological effects of this fungus are at present quite unknown. We have yet to learn whether the peculiar properties of ergotized grasses depend on the fungi, or on the morbid products of the ovarium.

Sub-order III. Gasteromycetes, Endl.

Character.—Sporidia free within a closed receptacle (peridium) collected together in the centre, or immersed and concrete, intermixed with floeci, or contained in proper receptacles (sporangia).

17. Elaphomyces granulatus, Fris.—Granulated Elaphomyces.

Lycoperdon cervinum, Linn.; Cervi Boletus, I. Bnh.; Elaphomyces officinalis, Nees; Tuber cervinum, Nees; Boletus cervinus; Hart's Truffles; Deer Balls. Sold at Covent Garden Market, as Lycoperdon nuts. (Elaphomyces, from Λικόφος, a stag; and μύκης, a fungus.) Rounded or oblong, from half an inch to two inches in diameter, brown, papillose verrucose, hard. Peridium internally white. Sporidia abundant, globular, black.—Indigenous. Grows underground.

A very complete analysis has been made by Biltz. The sporidia consisted of a disagreeable odorous volatile substance, soft resin, 0.325; hard resin, 0.052; red colouring matter, uncrystallizable sugar, with fungic ozmazone, 2.708; gum, 2.083; inulin, 8.333; soluble albumen, a trace; fungin, red colouring and albuminous matter, soluble in potash; free vegetable acid, vegetable salts of ammonia, potash, and lime, sulphate and phosphate of lime, chloride of sodium, silica, manganese, and iron. The ashes amount to 1.25. The peridium deprived of its warty coat consisted of yellow rancid, soft fat, 0.33; fungic ozmazone, with crystalline sugar, 15,000; gum, 10.40; albumen, fungin, gummy and albuminous matter, soluble in potash; free vegetable acid, vegetable salts of ammonia and lime, phosphate and sulphate of lime. The ashes amount to 1.1. The warty coat contains yellow, bitter fat, colouring matter, soluble in water and alkalies, but not in alcohol or ether; bitter and other substances, but neither sugar nor inulin. The capillitium contains sugar, but no inulin.

Though still remained in some of the best modern works on medical botany published on the continent, I have met with it in the stock of a London herbalist. I presume at no very long period since it must have been in use. "It was formerly used by apothecaries for the preparation of the bal-

samus apoplecticus; and great power was ascribed to it in promoting parturition and the secretion of milk. Even now the country people in some places esteem it as an aphrodisiac, and prepare from it a spirituous tincture. Parkinson\(^3\) says the dose of it is one drachm and a half in powder, taken with sweet wine, or with such other things as provoke venery.

18. *Lycoperdon giganteum*, Batsch.—**Giant Puffball.**

*Lycoperdon Boivista* (Giganteum), Fries; *Boivista gigantea*, Nees.—Sold in the London herb shops as the Common Puffball or simply as Puffball.—They are the *Fusseballs* of Parkinson.—In somewhat globular or obconical masses of variable size, sometimes one or two feet in diameter, and usually of a more or less yellow colour. *Peridium* very brittle, bursting in areola, evanescent, at length broadly open. *Capillitium* rare, evanescent together with the olive dingy-brown *sporidia*. This species, as well as *Lycoperdon celatum* of Bulliard, has been used in medicine under the name of *boivista*, *fungus chirurgorum*, and *crepitus lupi*. The spongy capillitium with the sporidia has been employed for staunching blood: thus it has been used as a plug in epistaxis, hemorrhage from the teeth, rectum, &c. The spongy base is employed as tinder. The fumes of this fungus, when burnt, are said to possess a narcotic quality, and have been employed to stupefy bees.

19. Tuber cibarium, Sibth.—**Common Truffle.**

*Lycoperdon Tuber*, Linn.; *Tuber*, Tourne.; *Tubera sincera*, Pliny, lib. xii. cap. 11. Dr. Sibthorp (Flora Gr. Prodr. ii. 332) considers it to be the *rubra* of Diosc. lib. ii. cap. 175: its modern Greek name being *ερυθρά* 

The truffle of the markets occurs in rough, rounded nodules, varying in size from a filbert to the fist, cracked into small subpyramidal warbs. Internally, it is marbled or veined. The white portions are filamentous, and are regarded by the Rev. M. J. Berkeley as constituting a sort of mycelium to the darker portions, which he calls the veins: the latter are cellular, and contain many subovate, shortly pedicellated *sporangia*, at first filled with a granular mass, which is ultimately collected into one or two globular, yellowish echinulate *sporidia*.

Fig. 186.

A truffle (natural size) from which a slice has been cut to expose the internal structure.

A section of a truffle (magnified).

a a. Cells.

b b c. Pedicellated peridiola or sporangia containing sporidia.

d. A sporidium (or spore) more highly magnified.

In France, three varieties of truffle are known:\(^4\) the *truffle de Perigord* with black flesh; the *truffle de Bourgogne* with white flesh; and a third sort with violet flesh. The first is the most esteemed, on account of its odour and tenderness. This fungus grows several inches below the surface of the ground in several parts of England. Covent Garden market is chiefly supplied from the downs of Wiltshire, Hampshire, and Kent. its odour is peculiar and penetrating, by which its presence is detected. In this country it is usually hunted by dogs trained for the purpose: in Italy, by pigs.

Rieger\(^5\) analyzed the dried Perigord truffles, and found them to consist of a brown *fat oil* (olein) with traces of *volatile oil*, an acrid *resin*, osmazone, *mushroom sugar*, *nitrogenous matter* insoluble

\(^4\) Merat and De Lenc, Dict. Univ. de Mat. Méd. t. vi. 783.

VEGETABLES.—NAT. ORD. FUNGI.

in alcohol, fungic acid, botelic acid, phosphoric acid, potash, ammonia, vegetable mucus, vegetable albumen, pectine, and fungine (fungic skeleton).

Truffles are a highly esteemed luxury at the table, being used as a seasoning or flavoring ingredient for ragouts, sauces, stuffings, &c. They are considered to possess aphrodisiac properties; and an Italian physician essayed to prove that births were more numerous in those years which correspond to the more abundant production of truffles!

Sub-order IV. PYRENOMYCETES.

CHARACTERS.—Peritheciun indurated, at first closed up, then perforated by a pore or irregular laceration, inclosing a softer nucleus. Sporidia immersed in mucus, or inclosed in ascu, which are attached by their base.

20. Sphaeria Sinensis, Berk.

This remarkable production is a highly esteemed article of the Chinese Materia Medica. It consists of a caterpillar or larva of a lepidopterous insect (probably a species of Agrotis), from whose neck projects the fungus, called by the Rev. M. J. Berkeley, Sphaeria Sinensis.

Sphaeria, Fries. Peritheciun rounded entire, furnished at the apex with a minute orifice. Ascu converging, at length dissolving.

S Sinensis, Berkeley. Brown; stem cylindrical, somewhat thicker downwards; head cylindrical, confluent with the stem, pointleted.

Du Halde says that it is produced in Thibet, and also on the frontiers of the province of Szechuen, which borders on Thibet, or Laza. It is brought to Canton in bundles tied up in silk (see Fig. 188); each bundle containing about one dozen individuals.

Each individual (see Fig. 187) is about three inches long, half being the caterpillar; the other half projecting from the back of the neck is the club-shaped fungus, attached by slender filaments, which spread over the surface of the larva. The substance of the caterpillar is replaced by a mass of fine branched threads, mixed with globules of oil. In none of the specimens examined by Mr. Berkeley were the perithecin developed.

In China, it is reputed as a strengthening and renovating substance, and is supposed to possess properties similar to those ascribed to ginseng. It is recommended in cases where the powers of the system have been reduced by over-exertion or sickness. But on account of its scarcity it is only used in the palace of the Emperor.
The mode of employing it is curious. The belly of a duck is to be stuffed with five drachms of this fungus, and the animal roasted by a slow fire. The virtue of the fungus is supposed to pass into the flesh of the animal, which is to be eaten twice daily for eight or ten days!

Sub-order V. Hymenomycetes.

Character.—Spores generally quaternate on distinct sporophores (basidia). Hymenium, naked.

Tremella Auricula Judae, Linn.; Peziza Auricula, Linn. This fungus grows on living trees, especially the elder; whence its name fungus sambuci, vel sambucinus. It is still professed to be kept in the London herb-shops; but in its place, I find that Polyporus versicolor, Fries, is usually sold for it. Dr. Martiny states that other species—namely, Polyporus adustus, Fries, Polyporus zonatus, Fries (especially when this is strongly dried and half charred), and Davadela unicolor, Fries, are substituted for the genuine plant. All these adulterations or substitutions may be readily detected by immersing the dried fungi in water: the genuine Exidia Auricula Judae softens and swells up so as to resume its natural gelatinous condition, whereas the others do not soften in water. It was formerly in repute as a topical astringent and diuretic, and was employed in the form of decoction or infusion (made with water, rose-water, vinegar, or milk), and castamplasm made with milk and water. It has been used in sore-throat, sore-eyes, and deafness. On account of its absorbing and retaining liquids, it has been soaked in collyria and applied to the eyes, as a substitute for sponge.

Phallus esculentus, Linn.; Helvella esculenta, Sowerby; Fungus faginosus, Lobel, Gerarde, Parkinson; Merulitus, J. Bauh. Hist. Pl.

This fungus is sold at the Italian warehouses, and at Covent Garden Market, in the dried and shrivelled state; and though a native of this country, is usually imported from the Continent. In the fresh state it is from 2 to 5 inches high, and hollow (see Fig. 189). The stem is white, from 1 to 3 inches long, and 1 inch in diameter. The pileus, which is confluent with the stem, varies in size from that of a pigeon's egg to that of a swan's egg; is deeply pitted or formed in irregular areoles, divided by anastomosing ribs, and varies in colour from a pale yellowish brown to olivaceous and smoke gray. The hymenium covers the whole pileus. The theca usually contain five globuliferous spores.

The Morell is a highly-esteem'd luxury at table. It usually enters into ragouts or other dishes; but is sometimes cooked by itself, being either stewed, or stuffed and dressed between thin slices of bacon. Though considered to possess nutritive qualities, it is employed at the table as a flavouring ingredient. Virey enumerates it among aphrodisiacs.

23. Polyporus officinalis, Fries.—Larch Agaric.

History.—This fungus was used by the ancients. It is described by Dioscorides under the name of Αγαρικός. In the modern Greek Pharmacopoeia, it is termed Ἀγαρίκος τολμικός, its Turkish name being Κατράν μαρμάρι.

Botany. Gen. Char.—Hymenium concretum, with the substance of the pileus, consisting of subrotund pores with their simple dissepiments. (Berkeley.)

Sp. Char.—Pileus corky-fleshy, ungulate, zoned, smooth. Pores yellowish (Fries).

Hab.—South of Europe and Asia, on the Larch.

Commerce.—The best agaric is brought from Asia and Carithia. A small and inferior kind is collected in Dauphiné. I was informed by the late Mr. Butler, of Covent Garden Market, that the London shops were supplied from Germany.

3 Bull. de Pharm. t. v. p. 303, 1813.

4 Lib. iii. cap. 1.
Levant Agaric (an inferior sort of which is known at Marseilles by the name of cucumule) is exported from Smyrna. The Russian larch agaric, exported from Archangel, is the product of Larix sibirica.⁴

Fig. 189. Fig. 190.

Morchella esculenta.
1. Morchella esculenta (nat. size).
2. A section of ditto.
3. Thecae and sporules magnified.

Polyporus officinalis.
(Represented as growing on the stem of a tree.)

Collection.—It is collected in the months of August and September, decorticated, dried, and bleached in the sun. Martiny states that it is beaten with wooden hammers to make it soft. But that which I have found in English commerce has neither been decorticated nor beaten.

Description.—This fungus is still kept in the herb-shops, being sold under the name of agaric, white agaric (agaricus albus), or larch or female agaric (fungus laricis). It occurs in masses, varying in size from that of the fist to that of a child's head. The most usual shape which I have found is that of a horse's hoof, or of half a cone (divided by a plane passing through both the apex and the base).⁵ Externally, it is yellowish or reddish gray; internally, it is white. It has a very feeble odour, and a bitter acrid taste. It is liable to be attacked by a beetle, the Anobium festivum, Panz.

Composition.—It has been analyzed by Bouillon-La-Grange;⁶ by Bucholz;⁷ by Braconnot;⁸ and by Bley.⁹

The constituents, according to Bley, are resin, 33.1; extractive, 2; gum and bitter extractive, 8.3; vegetable albumen, 0.7; wax, 0.2; fungic acids, 0.18; boletic acid, 0.06; tartaric and phosphoric acids, 1.354; potash, 0.329; lime, 0.16; ammonia and sulphur, traces. The following substances were obtained by the action of caustic potash and hydrochloric acid: coagulated albumen, 0.4; artificial gum, 15.5;

⁴ Martius, in Buchner's Repertorium, N. S. Bd. xli. S. 92, 1846.
⁵ The specimen from which Fig. 190 was taken was kindly lent me by the Rev. M. J. Berkeley. I have had it represented as growing on the stem of a tree.
⁷ Berlin, Jahrbuch fur 1806, p. 111.
⁸ Bull. de Pharm. t. iv. p. 304, 1812.
artificial resin, soluble in ether; 9.5; residual fibre called fungine (cellulose), 15;
mobility, 11, and loss, 2.367 = 100.000.

The active principle of agaric has been usually said to reside in the resin; but
Martius¹ states that it is a peculiar substance, which he proposes to call laricin.
This is a white amorphous powder, possessing a bitter taste, soluble in alcohol and
oil of turpentine, and forming with boiling water a paste. It has been analyzed by
Dr. Will, who found that its formula was C₄₄H₅₉O₄.

The resin of agaric possesses purgative qualities, and was formerly employed for
the adulteration of jalap resin.² It probably contains laricin.

Effects.—Larch agaric is an acrid substance. Its dust irritates the eyes, and
causes sneezing, cough, and nausea. When swallowed in the dose of a drachm or
two, this fungus excites nausea, vomiting, griping, and purging, and is said to check
sweating.

Uses.—It has been employed internally as an emetic, cathartic, discutient, and
to check colliquative sweating; externally, as an astringent. De Haen reported
favourably of it as an anti-sudorific in phthisis, and Barbut confirms his statements.
Favourable reports of it were also made by Toel, Neumann, Kopp, Burdach, Andral, and
others. Subsequently, however, Andral has expressed an opinion that little
benefit is to be derived from it.

Administration.—The dose of it is from 5 to 15 as a purgative; and from
grs. iiij to grs. viii, taken before going to sleep, to check sweating.³

Boletus igniarus, Linn.—An indigenous fungus found on willow, cherry, plum, and other trees,
and commonly known by the names of Agaric of the Oak (Agaricus seu Fungus Quercus; Aga-
ricus Quernus), or Surgeon’s Agaric (Agaricus Chirurgorum); Spunk; Touchwood. Formerly used
in surgery as a mechanical styptic, and still retained in some foreign pharmacopœias (e.g.
Pharm. Caesaris Rutheicus, 1840). It is prepared by decorticating it, cutting it into thin slices,
and beating it with a mallet until it has become sufficiently soft. Its action in restraining
hemorrhages is mechanical, like lint.⁴ In some places, both it and the following species are em-
ployed in the preparation of Amadou or tinder.

25. Polyporus fomentarius, Fries.—Real Amadou.

Boletus fomentarius, Linn.—Another indigenous fungus, found on the oak, birch, and other
trees. Its uses are similar to the preceding, and it might, with more propriety, be called Agaric
of the Oak, or Surgeon’s Agaric. The substance sold in the shops as Amadou, or German tinder,
is prepared from this, as well as the preceding species, by cutting the fungus in slices, beating
it, and then soaking it in a solution of nitre, and afterwards drying it. When impregnated with
gumpowder it is called black amadou. Amadou, or German tinder, has been recommended by
Mr. Wetherfield⁵ as an elastic medium for applying support and pressure, and as a defence
to tender and delicate parts; as in the form of a graduated compress, in umbilical hernia of new-
born infants, and as a compress over fistulous ulcers of the groin. It does not lose its elasticity,
like lint.

Agaricus duhls, Roques.—Fries⁶ considers this species to be the µπυς: λες: of Dioscorides
(lib. i. cap. 109); the Fungi qui rubent callo of Pliny (Hist. Nat. lib. xxii. cap. 47). Μαυτράπ
hodit Gt. Sibh.

Agaricus. Linn. Hymenium consisting of plates radiating from a common centre, with shorter
ones in the interstices, composed of a double closely connected membrane, more or less distinct
from the pileus. Vide various or absent.—Named from Agaricus, a region of Sarmatia (Berkeley).

¹ Buchner’s Repertorium, Bd. xii. s. 93, 1846.
² Jaquin, Diss. de Agarico OSt., Vind. 1778 (Richter’s Arzneimittelbuch, Bd. ii. S. 275).
³ For further details respecting its medical uses, see Murray, App. Med. vol. v. p. 573; Riecke, die
de neuer Arzneimitt. and Dunglison, New Remedies; and, for formulae for its preparation, see Jourdan’s
Pharmacopœia Universelle.
⁶ Systema Mycologicum, vol. i. p. 251, 1821.
A. campestris, Linn.; pleures fleshy, dry, subquamosse or silky, gills pink free ventricose, at length brown, stem stuffed, furnished with a ring white (Berkeley).

Pileus or caps 2-5 inches broad, at first convex, then plano-convex, white or light brown, silky or clothed with reddish brown adpressed fibrillae collected into little fascicles; epidermis easily peeled off, projecting beyond the gills, and often curled back, fleshy; flesh firm, thick, white, more or less stained with reddish brown, especially when bruised. Gills very unequal, at first of a beautiful pink, free, obtuse, and sometimes forked behind, broad in the middle; at length dark, mottled with brownish purple; the edge white, and minutely denticulate. Spores minute, elliptical, purplish brown immediately supported on spicules (sterigmatum) which surmount the sporophores (basidia).

Root consisting of branched fibres (mycelia). When quite young, there is a fine silky universal veil (Berkeley, with additions).

If the pleures be cut through, the fleshy part soon turns pink, and drops of pink juice may be squeezed out of it if young; but if old, the cut part, as well as the juice, is rather inclining to brown, but the Agaricus Georgii turns yellow. The whole plant is rather brittle, and has a fine scent peculiar to itself (J. Sowerby, Jun.).

The mushroom is artificially produced either with or without spawn. Mushroom spawn is the name given by gardeners to the white, branching, cottony fibres (mycelia), which form the so-called root of the mushroom, and upon which, at short intervals, are many very small round buds (the infant state of the plant). This spawn is collected and saved by gardeners, and at the commencement of autumn is planted on beds of dung, and covered with straw; in about two months the mushrooms come up, and rapidly increase. Mixed with dung, and made up into rectangular cakes, it forms what are called spawn cakes or spawn-bricks. These are sold at Covent Garden Market, and are planted in beds.

Mushrooms are also propagated without spawn. The principal ingredient employed in preparing the compost used for this purpose is horse-droppings. 2 "The artificial production of this species without the aid of spawn," says the Rev. M. J. Berkeley, 3 "has been frequently brought

---

1 Icones Selectae Anatomica-Botanica, Fasc. iii. Berlin, 1841.
2 See Loudon's Encyclopaedia of Gardening.
Mushroom; Champignon.

forward as an argument for the equivocal generation of fungi. But when it is considered how many millions of these sporules must be devoured together with the herbage by the animal, whose dung is a principal material in the compost, much of the force of this argument vanishes."

The young mushroom is gathered while the margin of the pileus is connected with the stalk by the veil, and at this period it is commonly called the button mushroom (Fig. 192, A a). The mature mushrooms are collected and sold as full grown or flap mushrooms (Fig. 192, B). Dr. Badham mentions a very large variety commonly called by peasants the ox-mushroom.

The mushroom was analyzed by Vaquelin, who found in it a brown-red fat, a spermaceti-like fat, mushroom sugar, peculiar animal matter, oznumose, albumen, fungine [cellulese], acetate of potash, and other salts.

This species is esculent, and in general wholesome; but it is employed at table for its savoury, rather than for its nutritive qualities. At times it proves indigestible and unwholesome; occasionally, perhaps, from some peculiarity in the quality of the mushroom, or from the mode of cooking it; but frequently from idiosyncrasy on the part of the sufferer. The particular circumstances, however, which render it unwholesome, are very obscure. Its use should be avoided by dyspeptics, by persons liable to pruriginous, exanthematos, and scaly diseases of the skin, and by those who have a highly susceptible nervous system.

The juice of the mushroom, flavoured with salt and aromatics, constitutes the sauce called ketchup (a word said to be derived from the Japanese kit-jap), which, though in common use at table, rarely produces any unpleasant effects when used in small quantities.

Agaricus Georgii, Withering.—This species, called St. George's Mushroom, because it grows up about St. George's day (April 23d), is said by the Rev. Mr. Berkeley to be frequently sold in London under the name of White Caps. But I have inquired for it by this name among the dealers in Covent Garden Market, but cannot meet with any one acquainted with it (Fig. 192, C).

It is larger than the common mushroom (A. campestris), which it resembles in shape. When bruised it soon turns yellow, and by this character may be readily distinguished from the common mushroom, which turns pink when cut. Its smell is strong and unpleasant. It contains but little juice, and that of a yellow colour, and is, therefore, not adapted for making ketchup.

Though not poisonous, it is less wholesome than the preceding species, and is usually rejected by housekeepers. It is very tough, and difficult of digestion.

27. Agaricus oreades, Bolton.—Champignon.

Agaricus oreades, Withering, Brit. Pl., vol. iv.; A. pratensis, J. Sowerby, Eng. Fungi; J. Sowerby, Jun. The Mushroom and Champignon illustrated; A. Pseudo-Mousseron, Bulliard; Fairy Ring Agaric; Scotch Bonnets.—This indigenous plant occurs in pastures, and is one of several fungi which grow in circles forming what have been termed Fairy-rings. It is commonly sold in the shops for use at table, and is liable to be mistaken for several other species of Agaricus, viz.: A. dealbatus, dryophilus, semiglobatus, and funiacei. Of these, A. dealbatus is the only one which, like the true champignon, forms "fairy-rings."

Fig. 193.

---

1 Treatise on Esculent Funguses, p. 85, 1847.
2 In the above cut, the figures marked a and b are from Mr. J. Sowerby, Jr.'s "Mushroom and Champignon Illustrated," the others, from Mrs. Hussey's Illustrations of British Mycology, part xiii. pl. xxxix. 1848.
The fungus varies in colour from a pale to a deep buff or mankeen colour. The stem is 1 or 2 inches high, and 2 or 3 lines thick, round, solid, often slightly twisted, readily splitting longitudinally into silky fibres, and is of the same colour as the gills. The pileus or cap is from \( \frac{3}{4} \) to 1 inch in diameter, irregularly round, convex, most elevated in the centre, tough and coriaceous. The gills free, distant, waved at the edges, often lacerated, paler than the pileus. If the pileus be cut through (Fig. 193, b) the gills will not be found to separate from it, but the fleshly part runs down the middle of each gill, which is covered by the continuation of the same buff-coloured coat that lines the under surface of the pileus between the gills—a structure widely different from the poisonous one \( [Ae. semi globatus] \). Taste and odour agreeable.

A. realbatus, Sowerby (Fig. 193, c d) is distinguished from the champignon by the margin of the pileus being at first rolled inwards, by its very fine dingy whitish gills, by its becoming grey-brown in zones when soaked in water, and by its disagreeable odour. This species, according to Mrs. Hussey, resembles the champignon more than any other; and like it also grows in fairy-rings.

A. semi-globatus, Batsch. (Fig. 193, i k); the \( A. virous \) of Sowerby is distinguished from the champignon by its dark-coloured gills, its hollow stem, and shining glutinous pileus. When young, this species has an annulus or ring, but this commonly disappears when the plant has attained its full size.

A. Fenisceti, Persoon (Fig. 193, l m), is distinguished from the champignon by its dark-coloured gills, its hollow stem, and its under-purple spores.

A. Brumiferus, Bulliard (Fig. 193, f g h), is distinguished from the champignon by its fine close gills, its hollow stem, and its reddened swollen base.

Like the Agaricus campestris, or mushroom, the \( A. oreades \), or Champignon, is used at table on account of its savoury qualities, and not for its nutritive power, which is probably very slight.

28. Fungi venenati.—Poisonous Fungi; Toadstools.

Many fungi are poisonous, and a still larger number frequently prove indigestible and unwholesome. The same species which may be taken with impunity by one individual will excite in another various inconveniences, such as nausea, vomiting, griping, diarrhoea, &c. Dyspepsia, and a highly susceptible condition of the nervous system, such as that called the hysterical constitution, dispose to those ill effects, which, in other cases, are ascribed to idiosyncrasy of constitution.

It must be obvious from these remarks that there can be no absolute anatomical characters by which the unwholesome can be distinguished from the wholesome species; the effects greatly depending on the constitution of the eater, or on some other insufficiently determined circumstances.

An illustrative fact of the truth of this statement has been adduced in the case of a French officer and his wife, who died in consequence of breakfasting off some poisonous Agaries, which were nevertheless eaten by other persons in the house with impunity. These, and other circumstances, have led to a general distrust of all fungi, except the cultivated ones; and so strongly was the late accomplished botanist, Professor L. C. Richard, impressed with this feeling, that, though no one was better acquainted with the distinctions of Fungi than he was, yet he would never eat any except such as had been raised in gardens in mushroom beds.

Of the genus Agaricus, all those species which belong to the subgenus \( Amanita \) are either actually poisonous or highly suspicious. The characters of this subgenus are thus laid down by the Rev. M. J. Berkeley:

\( Amanita \) (a name given to some esculent Fungus by Galen). \( Veil \) double: one universal, covering the whole plant in a young state, distinct from the epidermis, at length burst by the protrusion of the pileus, part remaining at the base of the stem, part either falling off, or forming worn on the pileus; the other partial, at first covering the gills, and afterwards forming a reflected subpersistent ring on the top of the stipes. \( Stem \) puffed, at length hollow, squamose fibrillosse, thickened at the base. \( Pileus \) with the disk fleshy, the margin thin, campanulate, then plane; viscid, when saturated with moisture. \( Gills \) attenuated behind, free, broader in front, ventricose, close, but little unequil; when full-grown, denticulated.

One of the most remarkable species of this subgenus is the \( Agaricus muscarius \), Linn. (\( Amanita muscaria \), Greville), the remarkable effects and uses of which have been already noticed (see ante, vol. i. p. 152).

\(^{1}\) Sowerby, Jr., The Mushroom and Champignon Illustrated.
The Russians, who eat no less than sixteen species of agaricus, never employ any belonging to the subgenus Amanita.  

Besides the species of the subgenus Amanita, many other Agarici are poisonous or suspicious. The symptoms produced by poisonous fungi are those indicating gastro-intestinal irritation (nausea, vomiting, purging and abdominal pain), and a disordered condition of the nervous system (delirium, stupor, blindness, convulsions, muscular debility, paralysis, and drowsiness). In some cases, the power of the vascular system is remarkably depressed, the pulse being small and feeble, the extremities cold, and the body covered with a cold sweat. At one time, local irritation only; at another, narcotism alone is produced.

In some cases the active principle of poisonous fungi seems to be a volatile acid principle; in other instances it is a brown, uncrystallizable solid, called by Letellier amanitin.

No specific antidote is known. The first object, therefore, is to expel the poison from the stomach and bowels. The subsequent treatment will depend on the nature of the symptoms which manifest themselves, and must be conducted on general principles.

Class II. Acrogenae, Ad. Brogniart.—Acrogenae

Pseudocottyledonae, Agardi; Heteronemae, Fries; Acrobrita, Mohl, Endlicher.

Character.—Substance of the plant composed of cellular tissue chiefly, and, in the higher forms, of vessels. Cuticle bearing stomata or breathing pores. Stem and leaves distinguishable. Oppression of stem and root. Stem growing at the point only.

This order includes a number of Orders, of which two only (viz. Lycopodium and Filices) need be here noticed as yielding anything useful in medicine.

Order IV. Filices, Juss.—Ferns.

Filicales, Lindley.

Character.—Herbaceous plants with a perennial rhizome, more rarely having an erect arborescent trunk [when they are called tree ferns, filices arboresae; Fig. 195); trunk coated, of a prosenchnymatous structure, with the entire cylinder of woody fasciculi divided into two concentric parts, the one narrow, placed between the bark and the wood; the other larger, central, medullary, sending fasciculi of vessels towards the petioles, and communicating with the exterior by means of chinks in the woody cylinder. Leaves [frondes] scattered upon the rhizome or rosaceo-fasciculate on the apex of the caudex, with circinate vernation, annual or perennial, the base of the petioles persistent, growing to the caudex; simple or pinnate, entire or pinnatifid, [equal] veined (the veins composed of elongated cells), frequently having cuticular stomata. Sporangia [here], placed on the veins of the back or margin of the leaves, collected in little naked heaps [sort], or covered with a membranous scale [indusium], or transmuted margin of the leaf, pedicellate [with the stalk (seta), passing round them in the form of an elastic ring (annulus)], or sessile, unilocular, indefinitely deliquescent. Spores [sporules] numerous, free, globose, or angular, in germination at first.

1 For some remarks on the Fungi used as food by the Russians, see Lyall's Character of the Russians, and a detached History of Moscow, p. 556, Lond. 1833.
2 Dr. Lelievre, Lond. Med. Gaz. xxiii. 414.
3 For illustrations of the effects of particular species, consult Pherebus, Deutschl. kryptog. Gifgewächse, 1838; and Letellier, Journ. de Pharm. Anét. 1837.
4 For further information respecting poisonous fungi, consult Christison's Treatise on Poisons.
VEGETABLES.—NAT. ORD. FILICES.

elongated in every direction, throwing out radicles downwards, and the culiculus upward (Endlicher).

Properties.—The leaves are mucilaginous, and frequently slightly astringent and aromatic. The rhizomes contain sugar, succharine matter and gum, usually tannic and gallic acids, with more or less bitter matter, and sometimes both fixed and volatile oils, resin. They are considered to possess astringent and tonic properties, and in some cases act as vermifuges.

From the tuberous rhizomes of fern is obtained, in some of the Polynesian islands, as well as in other parts of the world, a farinaceous or ligneous matter, which is employed by the natives as a nutritive substance. The rhizomes are cooked by baking or roasting. In general, however, they are only resorted to in times of scarcity, when other and more palatable food cannot be obtained.

Several ferns have been used in medicine. Those which I shall particularly notice are Nephrodium Filix mas, still retained in the British pharmacopoeias, and used as a vermifuge, and Adiantum or Maidenhair, a syrup of which, or a substitute for it, is still found in the shops under the name of capillaire.

Ruiz has written a memoir on three fern roots sent from Peru, in South America, to Spain, under the name of Calaguala (more correctly Cylindrohualia, from cullua, a button or trowel, and huau, a boy, i. e. a boy's button). The first, or the genuine Calaguala, or Cylindrohualia, or slender Calaguala, is the rhizome of Polypodium Calaguala, Ruiz; the second, called thick Calaguala, Puntuwantsi, and sometimes Deer's tongue (Lengua de Ciervo), is the rhizome of Polypodium crassifolium, Linn.; and the third, termed middling Calaguala, the little cord (Cor- doncillo), or Huacsaro, is the rhizome of Acrostichum Huascaro, Ruiz. The first is the species which should be used in medicine: as, however, it is unknown in English commerce, I need not describe it. Professor Guibourt has figured three sorts of the rhizome, but states that, judging from Ruiz's description, he has not seen the true Calaguala. He once found the Malese fungus (Cymonomorium coccineum) in some Calaguala which he received from Marseilles. Calaguala has been analyzed by Vaquelin. This rhizome is regarded in Peru as possessing deburstment, sudorific, diuretic, anti-venereal, and febrifugus virtues; and it is frequently used to thin the blood, to promote perspiration, and to mitigate rheumatic and venereal pains. It is commonly administered in the form of decoction, prepared by boiling one ounce of the fresh root in six pints of water to three pints. This decoction is taken ad libitum as a kind of diet drink.

29. NERIODIUM FILIX MAS, Richard.—MALE SHIELD FERN.

Sex. Syst. Cryptogamia, Filices. (Rhizoma.)

Synonymies.—Polypodium Filiz mas, Linn.; Aspidium Filiz mas, Swartz.

History.—Fern-root was employed by the ancients in medicine. Theophrastus

MALE SHIELD FERN:—BOTANY; DESCRIPTION.

notices two kinds of fern; the male, which he calls πτερίς, and the female, termed οφρυντιτις. Dioscorides\(^1\) also mentions these two ferns, and states that the πτερίς is by some persons called βαλσακιον, by others παλτροποιον. Pliny\(^2\) notices both ferns, and says the πτερίς is supposed to be the male fern (filix mas).

**Botany. Gen. Char.—**

*Sori* roundish, scattered. *Inclusium* orbiculareiform, fixed by the sinus.

**Sp. Char.—** Fronds bipinnate, pinnules oblong, obtuse serrated, their stalk and midrib chaffy. *Sori* near the central nerve (Hooker).

The rhizome is large, tufted, and scaly. The leaves grow in a circle to a height of 3 or 4 feet.

**Hab.—** It is an indigenous plant, frequent in woods and in shady banks. It is a native of other parts of Europe, of Asia, of the North of Africa, and of the United States of America.

**Description.—** The subterraneous stem (rhizoma; caudex; fern root, radix filicis, officin.) lies obliquely in the ground. It varies in length and breadth, according to its age. For medical purposes it should be from three to six or more inches long, and half an inch to an inch or more broad. It is almost completely enveloped by the thickened bases of the footstalks of the fallen leaves. These bases (phyllopodia) are arranged closely around the rhizome in an oblique direction, overlapping each other. They are one or two inches long, from three to five lines thick, curved, angular, brown, surrounded near their origin from the rhizome by two or more shining, reddish yellow, thin, silky scales (ramentum). The radicle fibres (root, properly so called) arise from the rhizome between these footstalks.

The fern root of the shops consists of fragments of the dried thickened bases of the footstalks (phyllopodia), to which small portions of the rhizome are found adhering, and of the root fibres.

Internally, the rhizome and footstalks are, in the recent state, fleshy, of a light yellowish-green colour; but in the dried state, yellowish or reddish-white. Iodine colours the fresh rhizome bluish black, indicating the presence of starch; particles of which may be recognized by the microscope. In a transverse section of the

---

rhizome, we observe five or six, or more, bundles of woody fibres and scalariform ducts. These bundles are arranged in a circle, are of a reddish-white colour in the recent rhizome, but yellow in the dried one.

The dried root has a feeble, earthy, somewhat disagreeable odour. Its taste is at first sweetish, then bitter astringent, and subsequently nauseous, like rancid fat.

**Collection.**—The rhizome should be collected in the month of July, August, or September. The black portions, fibres, and scales, are to be removed, and the sound parts carefully dried and reduced to powder: this is of a yellowish colour, and is to be preserved in well-stoppered bottles. Both the whole rhizome and powder deteriorate by keeping.

Fern buds (gemmae filicis maris) which are sometimes employed in medicine, are to be collected in the spring.

**Composition.**—Fern rhizome was analyzed in 1805 by Vaquelin, in 1821 by Gebhard, in 1824 by Morin, in 1826 by Wackenroder, and by Geiger. Subjoined are the results of the analyses of Geiger and Morin:

The anthelmintic property of the rhizome resides in the oil (oleum filicis maris). Luck obtained from the granular sediment which forms in oil of fern, tabular rhombic plates, whose formula was (H\textsubscript{2}O\textsubscript{2})(H\textsubscript{2}O\textsubscript{2}O\textsubscript{2}), a brown substance soluble in alcohol and alkaline liquids, and whose formula was C\textsubscript{8}H\textsubscript{4}NO\textsubscript{2}, and a gray body, insoluble in all solvents, except caustic alkalies, and whose formula was C\textsubscript{8}H\textsubscript{4}NO\textsubscript{2}.

Batsch found a peculiar acid (acidum filicum) and an alkali (filicina) in the rhizome.

Fern buds contain, according to Peschier, a volatile oil, brown resin, fatty matter, green-colouring principle, a reddish-brown principle, and extractive.

**Characteristics.**—The presence of tannic acid in the aqueous decoction of fern rhizome is shown by the sesquisalts of iron producing a dark green colour (tannate of iron), and by a solution of gelatin causing a yellowish precipitate (tannate of gelatin). No indication of the presence of a vegetable alkali in the decoction can be obtained by tincture of nutgalls. If the rhizome be digested in alcohol, and afterwards boiled in water, the decoction when cold forms, with a solution of iodine, a dingy blue precipitate (iodide of starch).

**Physiological Effects.**—These are not very obvious; but they are probably similar to those caused by other astringents. Large doses excite nausea and vomiting.

**Uses.**—It is only employed as an anthelmintic. Theophrastus, Dioscorides, Pliny, and Galen, used it as such. The attention of modern practitioners has been directed to it principally from the circumstance of its being one of the remedies employed by Madame Nouffer, the widow of a Swiss surgeon, who sold her secret method of expelling tape-worm to Louis XVI. for 18,000 francs. At the present time fern rhizome is but seldom employed in this country, partly because the efficacy of Madame Nouffer's treatment is referred to the drugs used, and partly because

8. Quoted by Soubeiran, Noue. Traité de Pharm. t. ii. p. 139, 2nd Ed.
OIL OF MALE FERN:—MAIDENHAIR; HISTORY; DESCRIPTION. 101

other agents (especially oil of turpentine) have been found more effectual. "It is an excellent remedy," says Bremser; "against Bothrioceros lotus [the tape-worm of the Swiss], but not against Tantia Solium [the tape-worm of this country]; for though it evacuates some pieces of the latter, it does not all of it."

ADMINISTRATION.—It may be administered in the form of powder, of oil or ethereal extract, or of aqueous decoction. The dose of the recently prepared powder is from one to three drachms. Madame Nourier's specific was two or three drachms of the powder taken in from four to six ounces of water in the morning fasting, and two hours afterwards a purgative bolus, composed of calomel ten grains, scammmony ten grains, and gamboge six or seven grains. The bolus was exhibited to expel the worm which the fern rhizome was supposed to have destroyed.

The Ethereal Tincture of Male Fern Buds (prepared by digesting 1 part of the buds in 8 parts of ether) has been used with success by Dr. Peschier (brother of the chemist of that name), and by Dr. Fosbrooke as a vermicule.

OLEUM FILICIS MARIS; Oil of Male Fern.—The impure oil of fern (called olium filicis Peschieri, extractum filicis whereum, seu balsamum filicis), recommended by Peschier, is an ethereal extract, and is composed, according to its proposer, of fatty matter, resin, volatile oil, colouring matter, extractive, chloride of potassium, and acetic acid. A pound of the rhizome yielded Soubeiran an ounce and a half of thick black oil, having the odour of fern. It may also be prepared from the buds as above stated. The dose is from half a drachm to a drachm, in the form of electuary, emulsion, or pills: an hour afterwards, an ounce or an ounce and a half of castor oil should be exhibited. Numerous testimonies of its efficacy have been published. I have tried it in several cases of tape-worm, but without success. By substituting alcohol for ether, twelve or thirteen drachms of oil can be obtained from 23 lbs. of the rhizome.

30. Adiantum, Linn.—Maidenhair.

HISTORY.—The term Maidenhair or Capillary (Capillaris, Apuleius; Capillaire, Fr.) has been applied to several species of fern which have been used in medicine. Dioscorides (lib. iv. cap. 136 and 137) and Pliny (lib. xxii. cap. 30) notice two kinds, one termed Adiantum, Polytrichon, or Callithrix (Διάιαντος, πολυτρίχον, καλλιθρίχον), the other called Trichomanes (τριχομανής). The former is supposed by Slithorpe to be the Adiantum Capillus Veneris, Linn., or True Maidenhair, the latter the Asplenium Trichomanes, Linn. Common Maidenhair Spilemore of modern botanists. In later times, other ferns have been also employed under the name of Maidenhair; especially Asplenium Adiantum nigrum, Linn. or Black Maidenhair Spilemore; Asplenium Ruta muraria, Linn. Well-rue or White Maidenhair, formerly called Selica Vitis; Ceratich officinarum, DC., or Rough Spilemore, and Selopendrium vulgar, Smith, or Common Hart's-tongue. To these must be added, Adiantum pedatum, Linn. or Canadian Maidenhair, and Adiantum trapeziforme, Linn. or Mexican Maidenhair.

The only species which it will be necessary here to notice are, Adiantum Capillus Veneris and A. pedatum.

BOTANY. Gen. Char.—Sporangia placed on the distinct points of the veins in a linear or point-like receptacle, arranged in marginal sori. Indusia continuous with the edge of the frond, united to the receptacle, opening inward (Endlicher).

2. A. pedatum, Linn. Frond pedate, divisions pinnate, pinnae halved, oblong lanceate, incised at the upper edge, the sterile segments toothed; sori linear; petiole smooth.—North America.

DESCRIPTION.—The official part of Maidenhair is the frond, or rather the whole plant without the root.

The herb of True Maidenhair (herba capillorum veneris) is sold at herb-shops in the dried state. When rubbed, it has a feeble odour, and its taste is sweetish and bitterish.

The herb of Canadian Maidenhair (herba capillorum veneris canadensis vel adianthi pedati) is more aromatic than the preceding.

2 Journ. génér. de Med. 1835, p. 375.
6 Nouv. Traité de Pharm. li. 101, 2nde éd.
COMPOSITION.—No analysis has been made of these species of Adiantum. The most important constituents appear to be tannic or gallic acid, bitter extractive, and a volatile oil.

EFFECTS AND USES.—None of the sorts of Maidenhair appear to be endowed with any active powers; though a great variety of imaginary properties have been ascribed to them. They are mucilaginous, bitterish, somewhat astringent, and aromatic substances; and in modern times have been used as pectorals in chronic catarrhs. The Canadian Maidenhair (Adiantum pedatum, Linn.) is the most esteemed sort, on account of its stronger and more agreeably aromatic qualities.

A Syrup of Maidenhair (Syropus Adianthii; Syropus Capillus Veneris; Sirup de Capillaire), prepared by adding sugar and orange-flower water to an infusion of Maidenhair, has long been popular. Both Baumé and the French Codeix direct it to be prepared with the Canadian Maidenhair. When diluted with water, it forms a very refreshing beverage. But as the Maidenhair serves no essential purpose in this drink, it is usually omitted, and the syrup sold in the shops under the name of capillaire is nothing but clarified syrup flavoured with orange-flower water. The Prussian and Hamburg Pharmacopoeias authorize this substitution by giving formulae for a syrupus florum aurantium to be used in “loco syrump capillorum veneris.”

ORDER V. Lycopodiaceae, DC.—CLUB-MOSSES.

CHARACTERS.—Herbaceous or shrubby vascular terrestrial plants. Stem terete, branched, leafy. Leaves inserted spirally on the stem, imbricated, simple, sessile or decurrent, never articulated. Spore cases (eporcarpia; therz; sporangia) axillary, mostly uniform, sometimes, on the same individuals biform; some bivalved, containing a farinaceous powder, composed of polygonal smooth or papillose-spinulose granules (sporules; pollen); others 3-4-coccos, 3-4-valved, containing a few (usually 3 or 4) somewhat globular corpuscles (spores?emme or buds?) marked at the vertex with a three-legged rapha.

PROPERTIES.—These are but little known.

An acrid principle resides in several species. Both Lycopodium clavatum and L. Selago act as emetics. The latter species, called muscus catharticus seu erectus, and supposed to be the Selago1 of the Druids, has also been employed as a cathartic emmenagogue, and to produce abortion. In large doses it operates as a narcotic-acid poison. A decoction of it is sometimes employed by the peasants of Sweden, and other places, as a lotion to destroy pediculi on the skin of horses, cows, pigs, &c. Dr. Buchner2 has recorded some cases of accidental poisoning by it, in which it caused staggering and sickness. Lycopodium catharticum, Hooker (L. rubrum, Chamisso) is also a violent purgative. Some species, e. g. Lycopodium Phlegmaria, Linn., and Selaginella convoluta, Spring (L. hygrometricum, Matt.) are reputed aphrodisiacs.

(Herba; Sporule.)

HISTORY.—The earliest writers by whom the medicinal qualities of this plant are distinctly referred to, are the herbalists (Brunsfels, Tragus, Cordus, &c.) of the 16th century.

BOTANY. Gen. Char.—Spore-cases unilocular, uniform or biform; the fariniferous ones subreniform, and bivalved; the globuliferous ones somewhat globose, 3-4-lobed, 3-4-valved. (Endlicher, Gen. Pl.)

Sp. Char.—Stem creeping; branches ascending; leaves linear-lanceolate, nerveless, terminating at the point in a bristle; spikes in pairs, stalked, cylindrical; bracts ovate, acuminate, premorse, toothed (Endl. Med. Planzen).

Roots of several strong scattered fibres. Stems procumbent, trailing, branching, leafy, several feet in length. Leaves crowded, curved upwards, linear-lanceolate, flat, ribless, smooth, deep green, partly serrated, tipped with a capillary point; those of the branches erect; the upper ones loosely dispersed. Spikes terminal, usually in pairs, rarely one, or three, densely beset with shortened, dilated, ovate, entire, long-pointed leaves or scales, in whose bosoms the small, sulphur-coloured capsules [thece] are situated (Smith).

1 Pliny, Hist. Nat. lib. xxiv. cap. 65.
3 Repert. für d. Pharmacie, Bd. xiv. s. 311, 1823.
COMMON CLUB-moss:—Description.

Fig. 198.

Lycopodium clavatum.
a. Scale of a spike with a capsule (magnified).

DESCRIPTION.—1. Sporulae Lycopodii. The powder sold in the shops under the name of lycopodium (pulvis, farina, pollen, seu semina lycopodii), witch-meal, or vegetable sulphur (sulphur vegetable), consists of granules, usually regarded as sporules, but by some considered to be grains of pollen. In both their physical and chemical properties they resemble the latter. They are gathered towards the end of the summer, and are separated from the capsules, &c., by sifting.

Lycopodium is a very fine, odourless, tasteless, and very mobile powder, of a pale-yellow colour. It adheres to the fingers, but exhibits a repulsive force for water, and hence is with difficulty mixed with it. If strewn on this liquid it floats, and the hand may be dipped to the bottom without being moistened. If shaken up with water a portion of it sinks, but the greater part floats. With spirit of wine it is readily miscible. It is tinged brown by iodine. When thrown into the flame of a candle it burns with great rapidity, producing an instantaneous flash of yellowish-white light.

When moistened by spirit of wine, or, still better, by oil of vitriol, and examined by the microscope, the granules are found to have the shape of tetrahedrons, with a convex base; or they may be described as spheroids, on a portion of whose surface there are three faces, or planes, uniting to form a three-sided pyramid. The faces appear to have been produced by the mutual pressure of the granules on each other, while in the spore-cases. The external membrane forms reticulated elevations, with intervening depressions or pits, giving a cellular appearance to the surface of the granules. The three-legged mark, at the union of the three planes, appears to be formed by a cleft in the membrane.

Fig. 199.
2. *Herba Lycopodiit (Herba musci clavati terrestris).* This is odourless; at first sweetish, and then bitterish. Digested in water it yields a yellowish infusion, whose colour is deepened by sesquichloride of iron.

**Composition.**—Lycopodium sporules have been analyzed by Bucholz\(^1\) and by Cadet.\(^2\) The former chemist obtained the following results:\(^3\) Fat oil, 6.0; sugar, 3.0; mucilaginous extract, 1.5; and pollenin, 80.5. The substance called pollenin is, however, a complex organized body, and cannot be regarded as a proximate principle. By the action of caustic potash on lycopodium, Muspratt\(^4\) has shown that acetic acid is obtained.

The herb has not been analyzed. It appears to contain some acrid principle.

**Adulteration.**—As met with in the London shops, I have never found lycopodium (the sporules) adulterated.

The sporules of other species of *Lycopodium* are said to be sometimes substituted for those of *L. clavatum*: the microscope alone can detect the difference.

The pollen of some plants, as of *Typha latifolia*, and of some coniferous plants, is said to be sometimes substituted for the lycopodium sporules. The microscope readily distinguishes the substitution. The shape, the size, the character of the surface, and the cohesion or isolation of the grains, must be attended to in distinguishing them. The pollen of coniferous plants is also sometimes recognizable by its terebinthinate odour when rubbed in the hand: that of *Typha latifolia* is not so inflammable as genuine lycopodium meal.

*Starch, talc, gypsum, chalk, boxwood powder, &c. &c.*, have been reported as adulterating substances. By throwing the suspected lycopodium on water, the mineral substances present would readily fall to the bottom, and might be detected by their appropriate chemical tests. Iodine and the microscope will detect starch. Boxwood powder has been separated from lycopodium by a fine sieve, which let the genuine sporules through, but retained the wooden particles.

Once I have seen lycopodium infected by a fungus, the matted mycelium of which had a slate colour, and a membranous or papery appearance.

**Effects.**—1. Of the sporules.—Applied externally, lycopodium acts as an absorbent and desiccant. Taken internally, it is reputed to possess demulcent, sedative, and diuretic properties; but these qualities are of doubtful existence.

2. Of the herb.—The herb appears to be endowed with some active properties. It acts as an emetic and cathartic, and is reputed to possess diuretic and emmenagogue qualities.

**Uses.**—1. Of the sporules.—Lycopodium is used both medicinally and pharmaceutically, as well as in the arts.

It is applied as a dusting powder to excoriated surfaces, especially the intertrigo of infants, and to parts affected with erysipelas, herpetic ulceration, eczema, &c. It is sometimes used in the form of ointment. In Poland, it is popularly employed as an external application in plica polonica. As an internal remedy, its powers are very doubtful. It has, however, been used by Wedelius and others,\(^5\) and, in later times, by Hufeland, Jawandt, Rademacher, and Busser,\(^6\) in the retention of urine, and flatulent colic of infants; and in calculated complaints, hemorrhoids, gout, &c., of adults.

In pharmacy, it is used for enveloping pills and boluses. It serves both to isolate the pills and cover their taste.

But its principal use is at theatres, where it is employed for filling flash-boxes, and for producing artificial lightning. It is also used in pyrotechny. Gray says that females employed in delicate works use it to keep their hands free from sweat.

2. Of the herb.—This is rarely employed. It has been celebrated in the treatment of plica polonica, and, in consequence, has been called *plicaria*. It was employed in the form of decoction, both externally, as lotion and liniment, and

Phanerogams or Flowering Plants:—Endogens.

1. More recently it has been recommended by Dr. Rodewald in retention of urine, from gravel, or pus [1], in atony of the muscular coat of the bladder, in weakness and relaxation of the inner membrane of the bladder, and as a diuretic. He states that he has used it for many years with great success.

Administration.—The spores are administered internally in doses of from ten grains to a scruple, in the form of a mixture, or emulsion, made with syrup, mucilage, or yolk of egg. Externally, they are sometimes used in the form of ointment, composed of one drachm of lycopodium to an ounce of lard. The herb is administered in the form of decoction or infusion. Two up-heaped tablespoonfuls, with a pint of water, are to be boiled to one-half; and of this decoction a teacupful may be taken every ten minutes, or at longer intervals. In a more dilute state it may be drank as a tea.

II. Phanerogamia, Auct.—Phanerogams or Flowering Plants.

Cotyledoneae, Juss.—Embryonate, Rich.—Vascularae, De Cand.

Characters.—Substance of the plant composed of cellular tissue, woody fibre, ducts, and spiral vessels. Leaves usually present; cuticle with stomata. Flowers with perceptible stamens and pistils. Seeds with an embryo enclosed within a spermoderm, furnished with one or more cotyledons.

Class III. Endogenae, DC.—Endogens.

Monocotyledones, Juss.

Characters.—Trunk usually cylindrical, when a terminal bud only is developed, becoming conical and branched when several develop. Consisting of cellular tissue, among which the vascular tissue is mixed in bundles, usually without any distinction of bark, wood, and pith, and destitute of medullary rays; increasing in diameter by the addition of new matter to the centre. Leaves frequently sheathing at the base, and not readily separating from the stem by an articulation, mostly alternate, generally parallel-veined, rarely netted. Flowers usually having a ternary division; the calyx and corolla either distinct or undistinguishable in colour and size, or absent. Embryo with but one cotyledon; if with two, then the accessory one is imperfect, and alternate with the other; radicle usually enclosed within the substance of this embryo, through which it bursts when germinating (Lindley, chiefly).

This class includes two subclasses: 1. Glumaceae, or glumaceous endogens. 2. Poaleside, or endogens, whose floral envelopes, if present, are whorled.

Sub-class I. Glumaceae, Endl.

Characters.—Flowers disposed in spikelets, and enclosed within imbricated bracts. Ovary free, unilocular, containing one erect ovule. Fruit a carpyopsis. Embryo at the base of the fruitaceous albumen.

This class includes two orders: 1. Gramineae, or glumaceous endogens with round stems, leaves having split sheaths, and embryo lying on the outside of the albumen. 2. Cyperaceae, or glumaceous endogens with angular stems, leaves with entire sheaths, and embryo included within the albumen.

1. Viau, Mémoire sur la Plante Polonoise (Murray, App. Med.),
ORDER VI. GRAMINEÆ, R. Brown.—GRASSES.

Gramina, Juss.—Graminaceæ, Lind.

CHARACTERS.—Flowers usually hermaphrodite, sometimes monoecious or polygamous; consisting of imbricated bracts, of which the most exterior are called glumes, the interior immediately enclosing the stamens palææ, and the innermost at the base of the ovary scales. Glumes usually 2, alternate; sometimes single; most commonly unequal. Palææ two, alternate; the lower or exterior simple; the upper or interior composed of 2, united by their contiguous margins, and usually with 2 keels, together forming a kind of dislocated calyx. Scales 2 or 3, sometimes wanting; if 2, collateral, alternate with the palææ, and next the lower of them, either distinct or united. Stamens hypogynous, 1, 2, 3, 4, 6, or more, 1 of which alternates with the 2 hypogynous scales, and is, therefore, next the lower palææ; anders versatile. Ovary simple: styles 2 or 3, very rarely combined into 1; stigmas feathery and hairy; ovules ascending by a broad base, anatropal. Pericarp usually undistinguishable from the seed, membranous. Albumen farinaceous; embryo lying on one side of the albumen at the base, lenticular, with a broad cotyledon and a developed plumule; and occasionally, but very rarely, with a second cotyledon on the outside of the plumule, and alternate with the usual cotyledon.—Evergreen herbs. Rhizoma fibrous or bulbous. Stems cylindrical, usually fistular, closed at the joints, covered with a coat of silicæ, sometimes solid. Leaves narrow and undivided, alternate, with a split sheath, and a membranous expansion (ligula) at the junction of stalk and blade. Flowers in little spikes, called locustæ, arranged in a spiked, racemized, or panicked manner (Lindley).

PROPERTIES.—Considered with reference to their ultimate or mineral constituents, the grasses are remarkable for the large proportion of silica, potash, and phosphoric acid, and for the small proportion of chlorine which they contain. The silica predominates in the leaves and stems, the phosphoric acid in the seeds. The following table represents the mean composition of the ashes of the most important cereal grains.

1 Drawn up from the calculated means contained in Johnston's Lectures on Agricultural Chemistry and Geology, 3d edit. 1847.
3 The proportions of azotized substances have been deduced from the elementary analysis by multiplying by 0.5 the weight of azote obtained.
GRASSES:—COMMON RICE.

Of the proximate or organic constituents of grasses, starch and sugar are found in large proportion, the former in the seed, the latter in the stem. These constituents, with proteinaceous matter (gluten, albumen), to which may be added gum, confer on corn its valuable nutritive properties. (For the per centage proportion of starch and proteinaceous matter in corn, see ante, p. 106, and vol. i. p. 119.)

Fragrant volatile oils are obtained from herbaceous parts of some grasses. Several of these are employed in perfume and in medicine (see the genus Andropogon).

The grasses are remarkable for their deficiency of pectin, as well as of pectic, tartaric, citric, and other vegetable acids commonly found in plants.

Considered with regard to their dietetical uses, the grasses are most important and valuable to man. They contain nitrogenized principles fitted for the production of the essential constituents of the blood and of the organized tissues, and also non-nitrogenized principles for the production of fatty matters, lactic acid, and, by combustion, of heat. The following table gives a general view of the uses which several constituents of grains of corn serve in the animal economy:—

Almost every species of grass is wholesome. Some supposed exceptions to this statement have been already noticed (see vol. i. pp. 134 and 135). Of these, the best established is Lolium temulentum, which will be presently noticed. In a state of disease, corn sometimes acquires most important and valuable medicinal properties. (See Ergot.)

TRIBE I. ORYZEE, Endl.

32. Oryza sativa, Linn.—Common Rice.

Sex. Syst. Hexandria, Digynia.

(Semina.)

BOTANT.—Stems numerous, 2 to 8 or 10 feet long. Leaves long and slender. Panicle diffuse thin, bowing when the seed is weighty. Spikdelet hermaphrodite, 1-flowered; glumes 2, small; palea 2; scales 2, smooth; stamens 6; ovary sessile; styles 2; stigma fethery. Caryopsis compressed, enclosed by the paleae.—Originally a native of Asia. Extensively cultivated in India, China, the Indian Archipelago, and most other Eastern countries; in the West Indies, Central America, and the United States; and in some of the Southern countries of Europe. Forty or fifty varieties are known to and cultivated by the Indian farmers; of these some are awned—others are awnless. The kinds most esteemed in this country are the Carolina and Patna rice. Patna rice is imported in bags holding 14 cwt. each. It has usually been mixed with lime, to prevent the attacks of insects. The grain, whilst enclosed in the palea or husk, is called paddie (padi or paddie) by the Malays, bra when deprived of the husk, and nasi after it has been boiled.

COMPOSITION.—Rice has been analyzed by Vaquelin, by Braconnot, by Vogel, and by d’Arce and Payen (see ante, p. 106). The composition of Carolina and Piedmont rice is, according to Braconnot, as follows:—

5 Journ. de chimie Méd. t. ix. p. 201, 1833.
The inorganic constituents of rice have been before stated (see ante, p. 106).

1. *Rice starch* is manufactured, under Mr. Orlando Jones's patent, as follows: Patna rice is first freed from stones, dust, &c., by a process analogous to winnowing, and is then digested whole in a solution of caustic soda containing 200 grains of soda to the gallon. The solution being poured off, the grain, which has thus been deprived of part of its gluten, is ground in a mill, and the ground rice mixed with a solution of the same strength, so as to form a mixture having the consistence of thick cream. More lye is then added, and the mixture stirred up for a few hours, and then left to deposit: a heavy matter, called *fibre* (heavy starch), deposits, while the starch (lighter starch) remains suspended.

The liquor is then run off into shallow vessels, where the starch deposits: the alkaline solution of gluten is then drawn off, and the starch repeatedly washed with water and then allowed to deposit. The starch mass is now obtained of the consistence of clay. It is then usually mixed with blue colouring matter (small), to fit it for the use of the laundress, and removed to draining-boxes, which are lined with cloth. These consist each of two cells, whose size is 3 feet long, 6 inches deep, and 6 inches broad. Here the starch forms a lump or mass of the shape and size of the cell, and is afterwards cut into 6 cubical blocks, which are placed on chalk-stones to drain, and are then partially dried in a stove, to produce what is called *crusting*. The crust is scraped off, the block wrapped in paper and returned to the stove to dry, when it splits into the columnar masses commonly known as the *race* of the starch. If, instead of crusting the lumps, the starch were slowly dried, decomposition is apt to take place; and, if rapidly dried, the races are apt to be small and needle-like. 100 lbs. of Patna rice, as it occurs in the market, yield from 80 to 85 lbs. of *good marketable starch*, 7.5 lbs. of fibre, the remainder being gluten, gruff or bran, and a small quantity of light starch, carried off in suspension in the alkaline liquor.

Vogel states that, from dried rice, he obtained 96 per cent. of starch.

When examined by the microscope, the granules are observed to be polygonal, and very minute; their average diameter being about $\frac{1}{4}$ of an inch. They are the smallest granules of all the commercial starches. According to Vauquelin, rice starch begins to dissolve in water at from 122° to 132° F.

Two kinds of rice starch are found in the shops: one, prepared under Orlando Jones's patent; the other, called *Mecllin glaze starch*, manufactured by Mottram, Relè & Co.

2. *Proteine matters*.—Rice contains a much smaller proportion of the so-called *gluten* than wheat does. According to Horsford and Payen (see ante, p. 106, and vol. i. p. 119), the quantity is about 7 per cent.

The substance which the rice starch-makers term *gluten* is analogous to what Mulder calls proteine, being obtained by carefully neutralizing the alkaline solution in which rice has been digested with an acid, by which a precipitate forms, which, when separated from the supernatant liquor, has a creamy consistence, an agreeable smell, and a bland taste, like pap. By

Most of the particles are angular; but the measurements were taken on those which most nearly approached the globular form.

evaporation, it forms a dark-coloured hard mass. If kept for some time in the moist state, it undergoes decomposition, and evolves an odour somewhat like sour yeast. Mixed with eggs, I have employed it, in the form of a baked pudding, in diabetes.

3. Fatty matters.—The quantity of fatty matter contained in rice is smaller than in other varieties of corn. The outer part of the grain appears to contain more than the inner part.

Effects.—Rice, though nutritious, is less than wheat: this is proved by chemical analysis, which shows the much smaller proportion of glutinous or nitrogenous matter found in the former than in the latter grain (see ante, p. 106, and vol. i. p. 119). "Rice," says Boussingault, 1 is held up as a most nutritious food; but though I have lived long in countries which produce it, I am far from considering it as a substantial nourishment. I have always seen it, in ordinary use, replace bread; and when it has not been associated with meat, it has been employed with milk. 2

The solid or dry part of rice does not materially differ from the solid or dry part of potatoes in the proportion of starch and gluten which it contains; and, therefore, as far as regards these two principles, the nutritious values of anhydrous rice and anhydrous potatoes are about equal. But, in some Union poor-houses, the substitution of an equal weight of boiled rice for potatoes was followed in a few months by scurvy. 3

Rice, when swallowed in the raw state, swells up in the alimentary canal, and acts injuriously by the mechanical distension it gives rise to. Mr. Hovel 4 has reported a case in which great pain, peritoneal inflammation, and death, arose from the ingestion of a tumblerful of raw rice.

"Rice," says Marsden, 5 "is the grand material of food, on which a hundred million of the inhabitants of the earth subsist, and although chiefly confined by nature to the regions included between, and bordering on the tropics, its cultivation is probably more extensive than that of wheat, which the Europeans are wont to consider as the universal staff of life." 6

Rice is less laxative than the other cereal grains. Indeed, it is generally believed to possess a binding or constipating quality; and, in consequence, is frequently prescribed by medical men as a light, digestible, unirritating article of food in diarrhoea and dysentery.

Various ill effects, such as disordered vision, &c., have been ascribed to its use; 7 but, as I believe, unjustly so. Neither does there appear to me to be any real foundation for the assertions of Dr. Tyler, 8 that malignant cholera (which he calls the morbus oryzus, or rice disease) is induced by it.

Uses.—Rice is employed as a nutriment in a variety of forms; e.g., boiled rice, rice milk, rice pudding, rice cakes, &c. In Chinn, rice vernicelli is prepared from it. This is sold in flat bundles (of about £ inches long, and 1½ inch broad), composed of a folded thread or filamente made of rice paste. Medicinally, rice is employed as a demulcent, somewhat binding, nutritious substance in diarrhoea, &c. Gardiner's alimentary preparation is very finely ground rice meal.

TRIBE II. PHALARIDEE.

33. Zea Mays, Linn.—Indian Corn; Maize.

Sex. Syst. Monoeilia, Trinandra.

(Semina.)

History.—Frumentum Indicum Mayis dictum, Cap. Banlin, Pinax; Frumentum vol Tricium Turricum; Turkish Corn or Wheat.—The first undoubted notice of this plant occurs in the works of Traugus, 9 who died in 1554; though by some writers it is thought to be referred to both in the Bible 10 and in the works of Greek and Roman authors. 11

Botany.—Stem 2 to 10 feet high. Leaves broad, flat, entire with a short ligula. Flowers monocious; males terminal, racemose; females axillary, densely spiked. Stamens 3. Ovary sessile ovate. Style 1, long, capillary. Stigmas ciliated. Carpopsides roundish or reniform, ar-

1 Ann. Chim. et Phys. lxvii. p. 413
2 Provincial Medical and Surgical Journal, June, 1847. Dr. Garrod (Monthly Journal of Medical Science, January, 1838) calculates that, prior to the substitution, the usual weekly food of the men in the Crediton Union contained 180 grains, and of the women 181 grains of potash; but, after the substitution, the weekly amount of potash taken by the men was about 61 grains, and by the women 66 grains, or a reduction of more than two-thirds, and he ascribes the occurrence of scurvy after the use of rice to the inferior proportion of potash which this grain contains in comparison with potatoes. We ought, however, also to take into consideration the fact that rice is deficient in certain vegetable acids found in the potato (see ante, p. 167).

4 Lancet, 1853-34, vol. l.
5 De Strupium Historia, p. 651, 1592. (Sprengel, Hist. Rer. Herb, t. i. p. 220, 1807.)
6 Genesis, ch. xii. ver. 5; Leviticus, ch. ii. ver. 14, ch. xxiii. ver. 14; Matthew, ch. xii. ver. 1, &c. See Gribbon's Treatise on Cobbett's Corn, ch. ii. 12, 1828.
7 Both Theophrastus (Hist. Plant, lib. viii. cap. iv.) and Pliny (lib. xiv. cap. xiii.) mention a Bactrian corn of remarkably large size. Theophrastus says the grains were as large as olive stones; and Pliny states that they were remarkable large as the ears of our corn. Franks (Synopsis Plant. Flora Class. p. 312, 1815) suggests that the Zizyphus of Strabo (lib. xv.) may be our maize.

ranged on a large cylindrical receptacle or rachis, popularly called the cob.—An annual plant, indigenous in tropical America, but cultivated in various parts of the world.

The ordinary colour of the ripe grains or carxopoides is yellow; but they are frequently met with white, party-coloured, red, purple, or even black.

Maize meal is sold in the shops under the name of polenta.

Composition.—Maize has been analyzed by Dr. Gorham,1 by Bizio,2 and more recently by Payen, whose analysis may be considered to have superseded his predecessors (see ante, p. 106).

1. Maize starch is not at present an article of commerce3 though a patent4 has been taken out for its manufacture by fermentation as well as by the action of enzistic and carbonated alkalies. The quantity of starch contained in dried maize is, in round numbers, about 67 per cent. (see ante, p. 106, and vol. i. p. 119).

When examined by the microscope, the particles of maize starch are seen to be more or less rounded or ovoid, with a very distinct either circular or slit hilum; but with no visible rings or laminae. Their shape is mostly somewhat irregular and knobby; some mulliar shaped. Owing to their mutual compression, many of the particles are angular or polyhedric: this is especially the case with those contained in the outer or horny portion of the albumen; while those found in the interior or flarianeous portion are more rounded. Occasionally, particles are seen with a projection like a stalk. The particles of maize starch are mostly of the medium size5 (.0005 to .0007 of an inch). By polarized light they show very distinct cresses.

2. Proteinaceous matters.—The quantity of gluten and other azotized constituents in maize is smaller than in wheat. Hornford6 obtained 13.65 per cent. from maize meal, and 14.65 per cent. from maize grains. But Payen (see ante, p. 106) found only 12.5 per cent. Partly in consequence of this smaller proportion of gluten, and partly from some difference in the quality of this substance,7 maize is less adapted for making bread than wheat.

3. Fatty matters.—Of all the cereal grains, maize appears to be richest in fatty matter. M.M. Dumas and Payen procured 9 per cent. of yellow oil from maize;8 but Liebig9 was able to obtain only 4.25 per cent. This oil consists, according to Fresenius, of carbon 79.68, hydrogen 11.53, and oxygen 8.79.

More recently, Payen10 has given 8.80 per cent. as the proportion of oil found in maize.

Effects.—Maize agrees generally with the other cereal grains in its nutritive properties (see ante, p. 107). It is remarkable for its softening quality, and which probably depends on the larger amount of fatty matter contained in it than in other cereal grains. In those unaccustomed to its use, it is considered apt to excite or keep up a tendency to diarrhoea.

Uses.—It is exclusively employed as an article of food.

---

3 The substance usually sold in the shops as Indian corn starch is potato starch.
5 The following measurements of seven (including the largest and smallest) grains of maize starch were made by Mr. George Jackson:—

1. .0010 of an English inch.
2. .0009 " " "
3. .0005 " " "
4. .0004 " " "
5. .0003 " " "
6. .0002 " " "
7. .0001 " " "

7 M. Guibourt (Hist. Nat. des Drogs. simpl. t. ii. p. 129, 4me éd. 1816) says that the gluten of maize contains less nitrogen than that of other grasses.
8 Comptes rendus, Oct. 24, 1842.
9 Annalen der Chemie und Pharmacie, Bd. xiv. S. 120, 1843.
TRIBE III. AVENACEÆ.

34. AVENA SATIVA, Linn.—THE COMMON OAT.

Sect. Syst. Triandria, Digynia.

(Semen tuniciis nudatum, L.—The seeds, E. D.)

HISTORY.—The oat is not mentioned in the Old Testament; but it is noticed by the ancient Greek¹ and Roman² writers, the former of whom called it βρυχος, the latter avea.

BOTANY. Gen. Char.—Spikelots three, many-flowered; flowers remote; the upper one withered. Glumes two, thin, membranous, awnless. Paleæ two, herbaceous; the lower one awned on the back, above the base, at the point almost bicuspitate; the upper one bicornate, awnless; awn twisted. Stamina three. Ovarium somewhat pyriform, hairy at the point. Stig mata two, sessile, distant, villose-plumose; with simple hairs. Scales two, smooth, usually two-cleft, large. Caryopsis long, slightly terete, internally marked by a longitudinal furrow, hairy at the point, covered by the paleæ, adherent to the upper one (?) (Kunth).

Hab.—Cultivated in Europe.

A considerable number of varieties of this species are cultivated; these may be arranged under the two heads of white oats and the red, dun, or black oats.

The white oats have the paleæ of a whitish or straw colour. To this division belong the potato oat, the Georgian oat, the Poland oat, and the Friesland or Dutch oat.

The red, dun, or black oats, are so called on account of their colour.

Besides the Avena sativa, several other species of Avena are cultivated as oats. The following are the chief:—

Avena orientalis, Kunth.—Tartarian, Hungarian, or one-seeded oat. Cultivated in Europe.

Avena brevis, Kunth.—Short oat. Germany, Austria, and Hungary. Cultivated in France and Spain.

Avena nudica, Kunth.—Naked oat. Cultivated in Europe.

DESCRIPTION.—Oats (caryopsis vel semina avenæ cruda) are too well known to need description. As found in commerce, they are usually enclosed in the paleæ or husk. When deprived of their integuments, they are called groats (semina integumentis nudata, L.; avena excerpta seu grutum): these, when crushed, are denominated Ember groats. Oatmeal (farina ex seminibus, D.) is prepared by grinding the grains. It is not so white as wheaten flour, and has a somewhat bitterish taste.

COMPOSITION.—Oats have been analyzed by Vogel,¹ by Payen,² and, more re-

² Pliny, Hist. Nat. lib. xviii. cap. 44.

³ For an account of the different sorts of cultivated oats, see The Agriculturist's Manual, by Peter Lawson and Son, 1836; and Supplement, 1842. Also, Loudon's Encyclopædia of Agriculture.

⁵ Précis de Chimie Industrielle, 1849.
VEGETABLES.—NAT. ORD. GRAMINEÆ.

cently, by Messrs. Norton and Fromberg; and oatmeal by Dr. Christison.¹ The results of Payen's analysis have been already stated (see ante, p. 106).

Four varieties of Scotch oats were analyzed by Messrs. Norton and Fromberg² with the following results:—

<table>

Oats consist of from 22 to 28 per cent. of husks; and of from 72 to 78 per cent. of grain.

The composition of the husk of the oat, according to Professor Norton, is as follows:—

<table>

The husk of the oat, therefore, though nutritive, is less so than the bran of wheat.

1. OAT STARCH, when examined by the microscope, is perceived to consist of small particles, whose normal shape is round; but which is modified by the mutual compression of the particles—some being mullar-shaped, from the mutual pressure of two particles—some being rounded at one end and dihedral at the other, from the mutual pressure of three particles—and others being polyhedral or many-angled, from the mutual pressure of many particles. The hilum is tolerably distinct in the rounded granules, but rings or laminae are not visible. The great bulk of the granules are of the medium size³ and polyhedral, frequently presenting a pentagonal outline. Unlike most other starches, little or no variation is observed in their appearance when they are viewed by polarized light; no crosses are visible.

2. AVENIN.—This is a proteine compound analogous to casein or curd of milk, and on it much of the nutritive value of oats depends. If oatmeal be washed on a sieve, and the milky liquid which runs through be left till the starch is deposited, then heated to 200° F. to coagulate the albumen, and to it, when cooled, acetic acid added, a white powder falls, which is avenin.

CHEMICAL CHARACTERISTICS.—Iodine forms, when added to the cold decoction of oats, the blue iodide of starch. Oatmeal, when mixed with water, does not form a dough as wheaten flour does; but by washing it with water on a sieve, the whole of the meal, with the exception of the coarse parts, will be washed through.

PHYSIOLOGICAL EFFECTS.—Oatmeal is an important and valuable article of food. With the exception of maize or Indian corn, it is richer in oily or fatty matter than any other of the cultivated cereal grains; and its proportion of protein compounds exceeds that of the finest English wheaten flour. So that both with respect to its heat- and fat-making, and its flesh- and blood-making principles, it holds a high rank.

A diet of unfermented oat-bread is apt to occasion dyspepsia in those unaccustomed to its use; and it was formerly suspected of producing or aggravating chronic

¹ Dispensatory
³ The following measurements of six (including large and small) grains of oat starch were made by Mr. George Jackson:—

| 1. | 0.0010 of an English inch. | 4. | 0.0003 of an English inch. |
| 2. | 0.0006 | 5. | 0.0002 |
| 3. | 0.0004 | 6. | 0.0001 |
skin diseases, but without just grounds. Oatmeal porridge, taken at breakfast, sometimes relieves habitual constipation.

Intestinal concretions, composed of phosphate of lime, agglutinating animal matter, and the small, stiff, silky bristles seen at one end of the inner integument of the oat, are sometimes formed in those who habitually employ oats as food: forty-one specimens, collected by Dr. Monro secundus, are still in the Anatomical Museum of the University of Edinburgh. These formations are now comparatively rare, probably because the oats are more perfectly deprived of their investing membranes before being ground (Christison).

USES.—The oat is employed dietetically and medicinally.

As a dietetical agent, it is employed in the form of oat-cake or unfermented oat-bread, oatmeal porridge or stir-about, and gruel. The latter is sometimes given to infants as a substitute for the mother's milk. When there is a tendency to diarrhoea, either in adults or infants, it is advisable to substitute wheatmeal for oatmeal.

In medicine we employ gruel, prepared from groats or oatmeal, as a mild, nutritive, and, in most cases, easily-digested article of food in fevers and inflammatory affections. It is also in general use after parturition; and is the basis of curd. In poisoning by acrid substances, it is employed as an emollient and demulcent. It is given, after the use of purgatives, to render them more efficient and less injurious. It is frequently used, either alone or in conjunction with other agents, as a clyster. Oatmeal is used for making poultices.

Oats are also employed by distillers for the production of spirit (see Alcohol).

DECOCTUM AVENAE; Oatmeal Gruel; Water Gruel.—This is usually prepared by boiling oatmeal or groats in water for about half an hour, and then straining. Dr. Cullen directs it to be prepared by boiling an ounce of oatmeal with three quarts of water to a quart, constantly stirring; strain, and when cold decant the clear liquid from the sediment. Sugar, acids, or aromatics may be employed for flavouring.

TRIBE IV. HORDEACEAE.

35. Lolium temulentum, Linn.—Bearded Darnel.

Sex, Syst. Triandria, Digynia.

(Semina.)

SYNONYMS.—Alfæus, Dios. lib. ii. cap. 122; Galeae, de simp! med. fac. lib. vi. § 10, and de aliment. facult. lib. i. cap. 37; Paulus. Æg. lib. vii. sect. iii.; Lolium, Pliny, Hist. Nat. lib. xxii. cap. 79; Lolium infelix, Virgil, Georg. i. 153.

HISTORY.—This grass was used medicinally by the ancient Greeks and Romans, though it is somewhat remarkable that it is mentioned neither by Hippocrates nor Celsius.

BOTANY. Gen. Char.—Spikes many-flowered, distichous, sessile, contrary to the rachis. Flowers beardless at the base. Glumes 2, nearly equal, herbaceous, lanceolate, channelled, awnless; the lower or inner ones very often deficient in the lateral spikelets. Palea 2, herbaceous; the lower concave, awnless, or awned below the point; the upper bicarinate. Stamens 3. Ovary smooth; styles 2, very short, inserted below the point; stigmas feathery, with long, simple, finely-toothed, transparent hairs; scales 2, fleshy, smooth, acute, entire or two-lobed. Caryopsis smooth, adhering to the upper palea (Kunth).

Sp. Char.—Spikelets about 6-flowered, equalizing or shorter than the glume. Outer palea as long as its awn. Root without barren shoots. Stem erect, 2 feet high, smooth and shining below, rough upwards. Ligule short. Inner glume usually present, often bifid.

Lolium temulentum, B. arvense, (Babington, Brit. Bot.) is a variety of the above. It is usually smaller and smoother; its spikelets 4- or 5-flowered; its awns either absent or at most short, lax, and weak.

Europe (indigenous), Japan, New Holland, Chili, Monte Video.—Annual.—Fl. July.

DESCRIPTION.—The grain (caryopsis) enclosed in the husk is ovato-oblong, on one side flattened and furrowed—on the other convex, greyish-brown; odourless, with a sweetish-bitterish, not disagreeable, taste. It yields a darkish meal or farina (called arina by Pliny).²

¹ Treatise of the Materia Medica, p. 290.
² Hist. Nat. lib. xxii. cap. 58.
Lolium temulentum, or Bearded Darnel.

**Composition.**—In 1827, Bizio\(^1\) examined darnel, and discovered in the seeds two peculiar substances, which he called respectively *gloyalico* and *lalico*; the latter he stated possessed a narcotic power similar to that of opium. In 1837, Marn-tori\(^2\) analyzed darnel seeds, and ascribed their poisonous properties to a peculiar acid. In 1834, Bley\(^3\) examined them, and obtained the following substances: Traces of volatile oil, chlorophyll 7.5, soft resin 3.6, bitter extractive with chlorides and sulphates 0.0, gum with chloride of calcium 6.0, sugar 0.7, albumen 0.65, extractive with malate of lime 1.55, gum with sulphate and muriate of potash 2.5, gum with malate of potash 3.0, starch 29.9, artificial gum and coagulated albumen 2.9, gluten 0.8, vegetable fibre 11.0, moisture 20.0 [loss 0.4\(^1\)]. Bley concluded that the poisonous principle of darnel was extractable from the seeds by water. Subsequently,\(^4\) he procured from the watery extract of darnel seeds a peculiar substance, which he called *lolin*. 1000 grains of the seeds yielded him 294 grains of starch.

*Lolium* is a foliated or pulvulent dirty white substance, soluble in hot and cold water, and in hot alcohol. Its aqueous solution reddened litmus paper feebly. A tenth of a grain of lolin caused an acid sensation in the throat, followed by an affection of the head and weakness of the whole body, which effects continued only for a short time.

**Chemical Characteristics.**—According to Ruspini,\(^5\) the properties of grains of Lolium temulentum in wheat-flour may be detected by digesting the suspected farina in rectified spirit. If the Lolium be present, the spirit immediately acquires a characteristic green tint, which gradually deepens; and the taste of the tincture is astringent, and so disagreeable that it may even excite vomiting. By evaporation it yields a green resin. But I have not succeeded in obtaining these results. By digesting bruised and coarsely powdered grains of Lolium temulentum in rectified spirit, the liquid had acquired in forty-eight hours a pale yellow colour and scarcely any flavour, and yielded, by spontaneous evaporation, a minute portion of yellowish residue with a saline taste.

**Physiological Effects.**

1. **On Animals.**—The effects of bearded darnel on animals have been examined by Seeber, Burghard, Mariotti, and Hertwig; and the general results establish the poisonous action of the seeds of this grass. Vomiting was a general effect; followed by tremblings, convulsions, insensibility, and augmentation of urine and sweat.\(^6\)

2. **On Man.**—The ill effects of the seeds of bearded darnel on man were known to the ancient Greeks and Romans. The symptoms which they produce are twofold: those indicating gastro-intestinal irritation—such as vomiting and colic; and those which arise from disorder of the cerebro-spinal system—such as headache, giddiness, languor, ringing in the ears, confusion of sight, dilated pupil, delirium, heaviness, somnolency, trembling, convulsions, and paralysis. These seeds, therefore, appear to be acro-narcotic poisons. According to Seeber, one of the most certain signs of poisoning by them is trembling of the whole body. Both Burghard and Schober (quoted by Wibmer) mention death as having resulted from their use. In Cordier's cases their ill effects were directly ascertained by experiments made upon himself; but in most other cases they were the results of accidental poisoning. In general, they have arisen from the intermixture of bearded darnel seeds with other cereal grains.\(^7\) In a prison at Cologne, sixty per-

7. See Christianon *On Poisons*; and Wibmer, *op. supra cit.*
sions suffered from the use of a bread-meal containing a drachm and a half of loliwm temulentum, in six ounces of meal.\(^1\)

Regarded in a medicinal point of view, bearded darnel appears to possess sedative and anodyne properties. Fantoni\(^2\) and Giacomini consider it to be a direct hypotensive (see vol. i. p. 134) depressing the cerebral circulation and acting like aconite.

Uses.—Darnel has been recently employed in headache, in rheumatic meningitis, and in sciatica. Fantoni used it with success in the case of a widow who, at the climacteric period, was affected with giddiness, headache, and epistaxis, which had resisted various other remedies. In a case of violent rheumatic meningitis, very great benefit was obtained by its use.

Administration.—The dose of powdered darnel is one or two grains every four or six hours in the form of powder or pill. It may also be employed in the form either of decoction or of extract. The extract is given to the extent of half a grain or a grain in the day.

Antidotes.—No specific chemical antidote is known. In the event, therefore, of a case of poisoning by darnel, our principal reliance must be on the use of evacuants and dynamical antidotes (see vol. i. p. 145). After the removal of the poison from the stomach and bowels, stimulants (such as ammonia, coffee, &c.) may be administered to relieve the depression.

### 36. HORDEUM DISTICHON, Linn.—TWO-ROWED OR LONG-EARED BARLEY.

**Sex. Syst.** Triandria, Dipygus. (Semen tunicis nudatum, L.—Decorticated Seeds, E. D.)

**History.**—Pliny,\(^3\) on the authority of Menander, says barley (hordeum) was a most ancient aliment of mankind. It was cultivated in Egypt nearly 1500 years before Christ.\(^4\) Hippocrates mentions three kinds of *barley*; namely, barley simply so called,\(^5\) three-month barley,\(^6\) and Achilles barley.\(^7\) These probably were *H. vulgare*, *H. distichon*, *H. hexastichon*.

**Botany.** **Gen. Char.**—Spicles three together, the lateral ones usually withered, two-flowered, with an upper flower reduced to a subulate rudiment. *Glumes* two, lanceolate-linear, with subulate awns, flattish, unequal sided, at right angles *contraries*, with the palea almost unilaterally, turned inwards *anticae*, herbaceous, rigid. *Pales* two, herbarious; the inferior one (turned inwards) concave, ending in an awn; the superior one (turned outward) contiguous to the rachis, bicaudate. *Stamina* three. *Ovary* hairy at the apex. *Stigmatas* two, sessile, somewhat terminal, feathery. *Scales* two, entire or augmented by a lateral lobe, usually hairy or ciliate. *Caryopsis* hairy at the point, oblong, with a longitudinal furrow internally, adherent to the palea, rarely free (Kunth).

**Sp. Char.**—The lateral *flowers* male, awhless; the hermaphrodite ones distichous, close pressed to the stem, awned (Kunth).

β. With naked seeds; *H. nudum*; *Naked two-rowed Barley*.—The grains of this variety separate from the palea or chaff-like wheat.

**Hab.**—A native of Tartary, cultivated in this country.

Several sorts of this species are in cultivation: such as the common two-rowed or English barley, the Chevalier barley, the Annat barley, Dunlop barley, golden or Italian barley, and black two-rowed barley (Hordeum distichon nigrum).

Besides *H. distichon*, several other species of *Hordeum* are in cultivation—namely, *H. vulgare*, or Spring Barley; *H. hexastichon*, or Six-rowed Barley; and *H. Zecitron*, Sprat or Battledore Barley.

**Description.**—The grains *caryopside vel semina hordei crusda* are too well known to need description. As found in commerce, they are usually enclosed in the palea or husk. Deprived of their husk by a mill, they form *Scotch*, *hulled*, or *pot barley* (*hordeum mundatum*). When all the integuments of the grains are removed, and the seeds are rounded and polished, they constitute *pearl barley* (*hor-
deum perlatum). The farina (farina hordei) obtained by grinding pearl barley to powder is called patent barley.

Fig. 204.

Hordeum or Barley.

a, H. vulgare. b, H. hexastichon. c, H. distichon. d, H. Zeocitron.

Three qualities of barley are distinguished in the market: the hard and flinty, fit for making pot barley; a softer kind, called malting barley, which is next in value; and feeding barley, which is adapted for neither of the uses of the two other kinds.

COMPOSITION.—According to Einfot, barley has the following composition:

<table>

Payen's analysis of barley has been already given (see ante, p. 106), as also the proportion of starch and proteine constituents according to Krocker and Horsford (see vol. i. p. 116). Mr. Johnston gives the following as the average composition of fine barley-meal: Starch 63; gluten, albumen, &c. 14; fatty matter 2; saline matter or ash 2; water 14 = 100.

1. Proteine Compounds.—The proportion of proteine matter in barley is much less than that in wheat, and its quality is very different. If barley dough be washed with water, nearly the whole is washed away, the husk alone excepted: it contains, therefore, little or no gluten properly so called. The milky liquid deposits starchy matter and an insoluble proteine matter (insoluble caseine?), while the clear liquid holds in solution a small quantity of albumen (caseinable by heat), and of caseine (precipitable by acetic acid). If the starchy deposit be digested with water containing ammonia, a solution of the proteine compound is obtained, from which a voluminous precipitate (caseine?) is thrown down by acetic acid. (Johnston.)

2. Starch.—Barley starch, like wheat starch, consists principally of large and small grains, but the larger of an intermediate size: but the diameter of the largest grains is somewhat larger than that of the corresponding grains of wheat starch. The shape of the larger grains is irregularly circular, or elliptical, or obscurely triangular, flattened or lenticular, the flattened surfaces being undulated or uneven: the smaller grains are globular, ellipsoidal, rarely angular or mullar.

Barley-Water; Malt. 117

shaped. The hilum is scarcely, if at all, perceptible on the larger grains, and the rings are very faintly indicated; in these respects the grains of barley starch differ remarkably from those of rye starch. On the smaller grains, a hilum, or what appears to be such, is frequently perceptible. By polarized light the cross is less distinctly seen than in rye starch. Barley starch offers more resistance to the action of boiling water than some other starches; and the insoluble residue, after the prolonged ebullition of it in water, constitutes what Proust\(^2\) called hordeine.

3. Fatte or Oily Matter.—Fourcroy and Vaquerin\(^3\) detected a yellow, acrid, saponifiable, butyric acid, in barley.

Chemical Characteristics.—Iodine forms the blue iodide of starch, when added to the cold decoction of barley. Decoction of whole barley has an acrid bitter taste, which it derives from the husk.

Physiological Effects.—Barley is a valuable nutritive. Considered in relation to wheat, it offers several peculiarities. In the first place it contains much less proteine matter; in other words, less of the flesh-and-blood-making principles; though Count Rumford\(^1\) considered barley-meal in soup three or four times as nutritious as wheat-flour. Secondly, its starch offers more resistance to the action of the gastric juice, in consequence of its more difficult solubility in water. Thirdly, its husk is slightly acrid; and, therefore, this should be removed from barley intended for dietetical purposes, as in Scotch and pearl barley. Fourthly, barley-meal is more laxative than wheat-meal.

Uses.—Barley is employed both dietetically and medicinally; as well also in the brewery and distillery.

Barley-meal is sometimes added to three times its weight of wheat-meal to form infant’s food; the addition of the barley-meal being intended to obviate the constipating effects of wheat-meal.

Scotch and pearl barley are employed to thicken soups, and to yield barley water. It is frequently used in the dietaries of pauper establishments; but when bowel complaints prevail, some of other cereal grain (wheat, for example) should be substituted for it.

1. Decoctum Hordei, L. D. [U. S.]; Aqua Hordeata; Barley Water.—(Barley [pearl barley] §iiss [§iss, D.]; Water Oivss [Oiss, D. (Barley §ij; Water Oivss, U. S.)].) —First wash away, with water, any foreign matters adhering to the barley seeds; then, half a pint of the water being poured on them, boil the seeds a little while. This water being thrown away, pour the remainder of the water, first made hot, on them, and boil down to two pints, and strain, L.—This is a valuable demulcent and emollient drink for the invalid in febrile cases and inflammatory disorders, especially of the chest and urinary organs. It is sometimes given to children as a slight laxative. It is usually flavoured with sugar, and frequently with some slices of lemon. It is a constituent of the Enema Aloes, L., Enema Terebinthinae, L., and Decoctum Hordei compositum, L.

The Muclago Hordei, Ph. D., is prepared with Ground Pearl Barley §iiss; Water $§$xvij.

2. Decoctum Hordei Compositum, L.; Mistura Hordei, E.; Decoctum Pectorale; Compound Decoction of Barley; Pectoral Decoction.—(Decoction of Barley Oj; Figs, sliced, §iiss; Liquorice [root] sliced and bruised $§$; Raisins [stoned] §iiss [and Distilled Water Oj, L.].) —Boil down to two pints, and strain.—The process of the Edinburgh Pharmacopoeia is essentially the same.—This decoction is emollient, demulcent, and slightly aperient. It is employed in the same cases as the simple decoction.

3. BYNE (§§vij.); Brasium; Maltum; Malt.—This is barley which has been made to germinate by moisture and warmth, and afterwards dried, by which the vitality of the seed is destroyed.—By this process part of the proteine matter of the barley is converted into diastase. This, although it does not constitute more than about

\(^{2}\) Essay on Feeding the Poor, 1800.

VEGETABLES.—NAT. ORD. GRAMINEÆ.

3/40 th of the malt, serves to effect the conversion of about 40 per cent. of the starch of the seed into grape-sugar, or gum (dextrine). The grain loses by the operation of malting about 8 per cent. of its weight, and gains about 1/10 th or 1/12 th in bulk. This loss arises in part from the separation of the radicles in the form of malt-dust or cummins. The colour of the malt varies with the temperature at which it is dried. If the temperature does not exceed 100° F., the result is pale malt; if it be above this and does not exceed 180°, the result is amber malt. These varieties of malt yield fermentable infusions. Brown or blown malt dried at 260° F. is used to communicate flavour; while roasted, burned, or high-dried malt, which has been scorched, is employed for colouring porter.

The infusion of malt (infusum bynes), commonly called sweet-wort, contains saccharine matter, starch, glutinous matter, and mucilage. It is nutritious and laxative, and has been used as an antiscorbutic and tonic. Macbride recommended it in scurvy; but it is apt to increase the diarrhoea. As a tonic it has been used in scrofulous affections, purulent discharges, as from the kidneys, lungs, &c., and in pulmonary consumption. The decoction (decoctum bynes) is prepared by boiling three ounces of malt in a quart of water. This quantity may be taken daily.

4. CERVISIA;⁴ Ale and Beer.—By the fermentation of an infusion of malt and hops are obtained ale and beer. These liquids consist of alcohol, sugar, mucilage, an extractive and bitter principle, fatty matter, aroma (volatile oil?), glutinous matter, lactic and carbonic acids, salts, and water. Common beer contains about 1 per cent., strong ale or beer about 4 per cent., best brown stout 6 per cent., and the strongest ale about 8 per cent. of spirit of sp. gr. 0.825. The ashes of beer consist of potash, soda, lime, chlorines, sulphuric acid, phosphoric acid, and silica.⁵ Beer is a thirst-quenching, refreshing, exhilarating, intoxicating, and slightly nutritious beverage.⁶

a. Ale is prepared with pale malt. It is, therefore, lighter coloured; and, when made with an equal weight of malt, is richer in alcohol, sugar, and gum, than porter or stout. Pale or bitter ale, brewed for the India market, has been carefully fermented so as to be devoid of saccharine matter, and contains an extra quantity of the active principles of hops. It is frequently used as a restorative beverage for invalids and convalescents.

b. Porter (the stronger kinds of which are called stout) owes its dark colour to high-dried orcharred malt. When fresh or new, it is said to be mild; and, when old and acid, is called hard. An extract of cocculus indicus, called black extract or hard mulsum, is occasionally used by dishonest dealers to augment its intoxicating quality. For medicinal purposes bottled porter (cervisia lageneria) is usually preferred to draught porter. It is used as a restorative in the latter stages of fever, and to support the powers of the system after surgical operations, severe accidents, &c.

¹ Hist. Account of a new Method of Treating Scurvy, 1767.
² See also a paper by Dr. Badmurch, Med. Obs. and Inq. vol. v. p. 61.
⁴ Playfair (Hist. Nat. lib. xxii. cap. 82, ed. Valp.), in noticing the drinks prepared from corn, says that "Zythum is made in Egypt, selia and ceria in Spain, and cervisia, and many more sorts, in Gaul." For cervisia, some writers use the term ceresia. Zythum (ἡζύθος) was a kind of beer obtained by fermentation from barley. (See Herodotus, lib. ii. cap. 77.) As cervisia was made from unmalted barley, its colour would be pale, and it would, therefore, in this respect, agree with our ale. But the ale and beer of the present day differ from the ancient cervisia in being flavoured with hops, and hence the phrase ceresia lupulata, which is sometimes applied to them.
⁵ Dickson, Phil. Mag. and Journal of Science, vol. xxxiii. p. 541, 1848.
⁶ For further details respecting the nutritive and dietetical properties of beer, see the author's Treatise on Diet, p. 415, et seq.
⁷ Ale, in Saxon cale or oale (probably from the word selia, before mentioned), is sometimes Latinized, ala or ailia.
37. TRITICUM VULGARE, Kunth.—COMMON WHEAT.

Sex. Syst. Triandria, Digynia.
(Farina; farina seminis: Amylum; seminis, fecula. L.: Amylum; fecula of the seeds, E. : The seeds, from which are prepared flour and starch, D.)

History.—In the earlier ages wheat was an esteemed article of food, and is frequently spoken of by Hippocrates, who calls it ῥύπος, and mentions three kinds of it: wheat, simply so called, three-month wheat, and Sitanian wheat. Pliny describes several kinds of triticum.

Botany. Gen. Char.—Spikelets three or many flowered: the fructiferous rachis generally articulated, flowers distichous. Glumes two, nearly opposite, almost equal, awnless or awned: the upper one bicarinate; the keels more or less aculeato-ciliate. Stamina three. Ovarium pyriform, hairy at the apex. Stigmata two, terminal, subsessile, feathery; with long, simple, finely-toothed hairs. Scales two, generally entire and ciliated. Caryopsis externally convex, internally concave, and marked by a deep furrow, distinct, or adhering to the pales (Kunth).

Sp. Char.—Spike four-cornered, imbricated; with a tough rachis. Spikelets generally four-flowered. Glumes ventricose, ovate, truncate, mucronate, compressed below the apex, round, and convex at the back, with a prominent nerve. Flowers awned or awnless. Grains loose (Kunth).

a. aestivum, Kunth; T. aestivum, Linn. D.; Spring or Summer Wheat.—Annual; glumes awned.—This variety includes a great many sorts known to farmers by different names, and which may be arranged in two divisions—viz., the white bearded and the red bearded.

b. hybernum, Kunth; T. hybernum, Linn.; T. compactum, Host.; T. vulgare, Schnebl.; T. erinaceum, Hort. Hal.; Winter Wheat.—Biennial; glumes almost awnless. This variety also includes many sorts, which may be arranged in two divisions—viz., the white beardless and the red beardless.—Talavera wheat is a white beardless winter wheat. Mr. Hard, miller, of Dartford, tells me that this kind (Talavera wheat) is far superior to any description of wheat, either foreign or English; and the great advantage it possesses consists in its strength, colour, and sweetness. The reason of there being so small a quantity at market, arises from the fact of its being so

3 De vietiis rat. lib. iii. p. 374, ed. Fossii.
4 The distinction of wheats into summer and winter wheats, or into those sown in the spring and those sown in the autumn, has been objected to on the ground that under the name of T. hybernum are included several of the earlier sorts of spring wheat, and under T. aestivum, are included several wheats which require as long a time to arrive at maturity as the common winter sorts.
unprofitable to the farmer, scarcely producing one crop in three, which I greatly regret, as it is
the most valuable grain we have; and, technically speaking, if the flour is properly manufac-
tured, 8 oz. will absorb as much liquor as 11 oz. of that used by the baker."

Hab.—It is a native of the country of the Baschkirs, and is cultivated in Europe.

Besides T. vulgare, other species of Triticum are cultivated. The following are the chief:—

T. TURRIBUM, Kunth; Turgid Wheat. Some of the sorts of this species have smooth ears;
others downy, woolly, or velvety ears.—This species includes the T. turgidum, Linn. and T.
compositum, Linn.

T. DURUM, Kunth; Hard or Horny Wheat,
T. polonicum, Kunth; Polish Wheat.
T. Spera, Kunth; Spelt Wheat.
T. monococcum, Kunth; One-grained Wheat.

Description.—Wheat-grains (caryopsides tritici; semina tritici), as brought to
market, are completely devoid of their palea (chaff or husk).

The number of parts into which millers separate wheat varies in different locali-
ties. According to Mr. Hard, miller, of Dartford, in Kent, the products obtained
by grinding one quarter or eight bushels of wheat are as follows:

<table>
<thead>
<tr>
<th>Produce of one quarter of wheat weighing 504 lbs.</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Flour</td>
<td>399 lbs.</td>

</tr>
</tbody>
</table>

Wheat-grains vary in size, smoothness, transparency, and hardness, and in
the thickness of their integuments; and, consequently, the relative proportions of bran
(and pollard) and flour which they yield vary. The integument readily separates
in soft-grained wheat, but with difficulty in the hard-grained: the former, therefore,
yields more bran and less flour; while the latter produces flour of a lower quality,
because it is intermixed with some of the ground integuments.

Semolina, Soujoe, and Manna Croup are granular preparations of wheat, de-
prived of bran.

I am indebted to Mr. Hard for the following notice (as well as for samples) of
the products obtained in grinding wheat:—

"The wheat having been ground in the usual way, should be allowed to remain
in the meal for some time before dressing, which removes the heat caused by the
process, and enables the miller to obtain more flour, and the baker a better quality,
than if dressed immediately it is ground.

"The process of dressing is by a wire cylinder containing a certain number of
sheets of different texture or fineness, which cylinder contains eight hair-brushes
attached to a spindle passed through the centre of the cylinder, and laid out so as
to gently touch the wire: this cylinder is fed by a shoe with the meal; then the
flour and offal, after passing through the wire in this way, are divided by wood par-
titions fixed close to the outside of the cylinder. The produce of wheat-meal dressed
through the wire machine consists of—1st, Flour; 2d, White Stuff or Boxings, or
Sharps; 3d, Fine Pollard; 4th, Coarse Pollard, or Horse Pollard; 5th, Bran.
The second product (i.e. the White Stuff) is then submitted to another dressing
through a fine cloth machine, and produces—1st, Fine Middlings, for biscuit; 2d,
Toppings or Specks; 3d, Dustings; 4th, Best Pollard, Turkey Middlings or Coarse
Middlings.

Composition.—1. Wheat-flour has been analyzed by Vogel, by Proust, by
Henry, and by Vaquelin. The following are the results obtained by Vaquelin.

1. The term Manna Croup is probably derived from Manna-Grout, the name of a nutritious food
prepared from the grain of Glycera fluitans. (See Curtis, Fl. Lend. vol. 1. pl. 7; also, Tooke's View of the
Russian Empire, vol. iii. p. 168–30 edit. 1836.)
4. Journ. de Pharm. t. viii. p. 31, 1822; and t. xvi. p. 127, 1822.
5. Ibid., t. viii. p. 533, 1822.
Payen's analysis of wheat has been already given (see ante, p. 106); as also the proportions of water, proteine matters, and starch, according to the investigations of Horsford and Krocker (see vol. i. p. 116); and the composition of the ash of wheat (see ante, p. 106).

Mr. Johnston found that in 20 samples of English flour the proportion of water varied from 15 to 17 per cent.

The proportion of the organic constituents of wheat is liable to considerable variation, according to soil, climate, variety of seed, mode of culture, time of cutting, and quality of manure.

2. The composition of bran, like that of wheat-flour, is subject to great variation; but the following is given by Mr. Johnston as the average:

### Composition of Bran.

1. Starch.—As wheat-starch is an article of the materia medica, it will be noticed among the official preparations (see ante, p. 124).

2. Proteine Matters.—The quantity of proteine matters in wheat has been already stated (see vol. i. p. 116, and vol. ii. p. 123). Wheat contains at least four different proteine compounds, namely, albumen, vegetable, fibrine, gluten, and caseine. They have an analogous composition, and contain each about 15 per cent. of nitrogen.

If wheaten-dough be washed on a sieve by a stream of water, a milky liquid passes through, and a tenacious elastic mass is left behind called crude gluten, or sometimes Beccaria's gluten. The milky liquid holds in solution gum, sugar, and albumen; and in suspension starch: the crude gluten contains vegetable fibrine, gluten, caseine or mucine, and oil. According to Saussure, crude gluten has the following composition:

### Composition of Crude Gluten.

<table>

</tbody>
</table>

a. Vegetable Albumen.—Obtained by allowing the milky liquid above mentioned to deposit its starch, and then heating the supernatant liquor nearly to boiling: flakes of coagulated albumen are formed. Its composition was found by Dr. Bence Jones to be carbon 55.01, hydrogen 7.23, nitrogen 15.92, oxygen, sulphur, and phosphorus 21.84.

b. Glutin; Gladiine (from γλιν, glue); Pure Gluten.—Obtained by boiling crude gluten in alcohol, which extracts glutin, caseine or mucine, and oil. By cooling, the caseine is deposited. The supernatant liquid is then evaporated to dryness, and the adhesive mass thus obtained digested with ether to extract the oil: the residue is glutin. Its composition has been before noticed (see vol. i. p. 112).

c. Vegetable Fibrine; Zymome (from ζύμη, ferment).—This is the part of crude gluten which is insoluble in alcohol. Mulder considers it to be coagulated albumen; Liebig as vegetable fibrine. Johnston, on the other hand, thinks it different from both albumen and fibrine, and.
VEGETABLES.—NAT. ORD. GRAMINEE.

therefore, calls it simply gluten. When obtained as above described it much resembles the fibre of lean beef. Dr. Bence Jones ascertained its composition to be carbon 55.29, hydrogen 7.42, nitrogen 13.98, oxygen, &c., 21.98.

2. Caseine.—After the albumen has been separated by heat from the aqueous liquid before alluded to, the addition of acetic acid causes the separation of what is supposed to be caseine. The white flocculent substance, which deposits on cooling from the alcoholic liquor in which crude gluten has been boiled, and which has been called mucine, somewhat resembles caseine.

3. Oil.—Obtained by digesting wheat flour in ether. The quantity procured varies from 1½ to 3 per cent. As bran yields about twice as much as fine flour, it follows that the oil exists in greater proportion in the outer than in the inner part of the grain. The oil resembles the fatty oils or butter in its properties. By washing wheat-dough, part of the oil is washed out, and part remains in the crude gluten.

4. Water.—According to Johnstone, English flour contains, on an average, from 15 to 17 per cent. of water.

5. Mineral Constituents.—The composition of the ashes of wheat has been already stated (see ante, p. 106). The most important of these constituents are the alkaline and earthy phosphates.

Chemical Characteristics.—The cold decoction of wheat-flour forms, with tincture of iodine, the blue iodide of starch. Nitric acid gives wheat-flour a fine orange-yellow colour. Recently-prepared tincture of guaiacum forms a blue colour with good wheat-flour.

Diseases of Wheat. 1—Five diseases of wheat are produced by the attacks of parasitic fungi; namely, 1st, bunt, smut-balls, or pepper-brand, produced by Uredo Caries, De Candolle; 2dly, smut, dust-brand, or burnt-ear, produced by Uredo segetum; 3dly, rust, red-ray, red-robin, or red-gum, caused, as Professor Henslow has shown, by the young state of Puccinia graminis, which was formerly supposed to form two distinct fungi, to which the names of Uredo Rubigo and U. linearis had been given; 4thly, mildew, produced by the Puccinia graminis in a more advanced period of its growth; and 5thly, ergot, caused by the Oidium abortifaciens (see ante, p. 87).

Two diseases of wheat are produced by parasitic animalcules; namely, first, the ear-cockle, purples, or peppercorn, caused by a microscopic, oval-shaped animalcule, called Vibrio Tritici; and, secondly, the wheat-mildie, an abortion of the grain caused by a minute two-winged fly called Cecidomyia Tritici.

Corn affected with any of these diseases is of course deteriorated in value; but we have still to learn what are the precise effects on the animal economy of grain thus infected. The bunt imparts to flour its disgusting odour, and makes it less fit for bread; but flour thus tainted is used in the manufacture of ginger-bread. Smut does not give any unpleasant odour to corn, which, when infected with it, is frequently used for feeding fowls, apparently without producing any ill effects. I have ascertained that ergot of wheat is as powerful in its action on the uterus as ergot of rye. It has been suggested that some remarkable cases of spontaneous gangrene which occurred at Wattisham, in Suffolk, in 1762, may possibly have arisen from the presence of ergot in the corn used by the persons affected; but of this there is no evidence.

Deterioration; Adulteration.—By exposure to a damp air, wheat-flour absorbs moisture, and, after some time, acquires a musty odour, and becomes mouldy; the gluten being the first to suffer change. In this state it may be readily conceived that wheat-flour would prove injurious to health.

Wheat-flour is subject to adulteration with various vegetable and mineral substances.

Among vegetable substances used for the purpose of adulterating wheat-flour, the following have been named: potato starch, the meal of other cereal grains (viz., of maize, rice, barley, and rye), of buckwheat, and of certain leguminous seeds (viz., of beans, peas, and vetch).

In the detection of these adulterations, the microscope lends important assistance.

It enables us to judge of the size and shape, the markings on, and the isolation and agglomeration of, the starch grains, and thereby to distinguish the starch grains of one meal from those of another.

In some cases, the microscopic examination of suspected flour is aided by the use of a solution of potash. Thus it enables us readily to detect the presence of either potato starch or the meal of leguminous seeds. If a solution containing about 1¼ per cent. of potash has been added to a mixture of potato-starch and wheat-starch (or wheat-flour), the granules of potato-starch swell up, and acquire three or four times their original volume, while those of wheat-starch are scarcely affected by it. A solution of potash, containing about 12 per cent. of potash, dissolves all the varieties of starch, but not cellulose; hence, if to wheat-flour, intermixed with the meal of some leguminous seed, this solution be added, the starch grains dissolve, and the hexagonal tissue of the adulterating leguminous seed is rendered very obvious.3

Occasionally, polarized light may be used to aid the microscope in detecting adulterations of wheat-flour. Thus, unlike wheat-starch, the starch of the oat produces no effect on polarized light, and presents no crosses when viewed by it.

In the detection of the meal of the leguminous seeds, the odour and flavour of the suspected flour, and its chemical characters, aid in detecting the fraud. If the suspected flour be digested with twice its volume of cold water, the infusion filtered and a few drops of acetic acid added to it, a precipitate of legume (a kind of caseine) is produced, if the meal of a leguminous seed be present; but wheat-flour, treated in the same way, yields a slight precipitate (of caseine), and, therefore, this test must not be relied on. Donny has pointed out a mode of detecting the meal of two leguminous seeds, viz., the vetch (Vicia sativa), and beans (Faba vulgaris, common tick bean): it consists in exposing the suspected flour to the successive action of the vapours of nitric acid and ammonia: wheat-flour, when thus treated, becomes yellow; but the meals of the leguminous seeds just referred to become red, and hence, wheat-flour adulterated with either of them becomes more or less spotted with red, according to the proportion of the leguminous meal present.

The mineral substances which have been used to adulterate wheat-flour are chiefly chalk and sulphate of lime (plaster of Paris). White clay and bone-ashes are also said to have been used. Sulphate of copper and alum are sometimes added to bad wheat-flour to improve its quality and render it more fitted for making bread. These different adulterations may be readily detected. Their quantity and nature may be judged of by incinerating the suspected flour, weighing the ash (which in genuine flour amounts to about 1 or 1¼ per cent.), and determining its nature. Flour mixed with chalk effervesces on the addition of hydrochloric acid, and yields a calcareous solution detectable by a solution of oxalate of ammonia (see vol. i. p. 568). Flour mixed with sulphate of lime, when digested in water, yields a solution which answers to the tests both for lime (see vol. i. p. 568) and for sulphuric acid (see vol. i. p. 368). Pure wheat-flour is almost completely soluble in a strong solution of potash containing about 12 per cent. of alkali; but mineral substances used for the purpose of adulteration remain undissolved.

**Physiological Effects.**—The nutritive qualities of wheat are similar to those of the cereal grains generally, and which have been already noticed (see ante, p. 107).

As it exceeds other kinds of corn in the proportion of proteine matters which it contains, so it surpasses them in its flesh- and blood-making qualities. But, as it contains less starch and fatty matters than some other cereal grains, it is probably inferior to the latter as a fattening agent.

---

1 I find that a mixture of 1 measure of *liquor potassa*, Ph. L., and 2 or 3 measures of distilled water, readily distinguishes potato-starch from wheat-starch.

3 *Journal de Pharm. et de Chim.* 3me Sér. t. xi. p. 322, 1847; also, *Pharmaceutical Journal*, vol. vii. p. 84, 1847.
The different parts of the grain differ in composition, and, therefore, in nutritive value. The external sub-epidermoid part contains a larger proportion of oil, of salts (chiefly phosphates), and albuminous and caseine matter than the more internal and farinaceous portion; and it is, therefore, probable that the finest flour, which has been freed as much as possible from all traces of bran, is actually somewhat less nutritive than the coarser flour.

Wheat-flour, especially when baked, is rather constipating than purgative. In this it differs from both barley-meal and oat-meal. Infants who are fed on baked flour frequently suffer with constipation; and to relieve this it is sometimes found necessary to substitute a portion of barley-meal for an equivalent weight of wheat-flour.

Wheat-flour yields the finest, whitest, lightest, and most digestible kind of bread. It owes its superiority in these respects to the large quantity of tenacious gluten which it contains.

Undressed wheat-flour appears to act, by the bran which it contains, as a mechanical stimulant to the bowels; and hence brown bread is resorted to for the purpose of counteracting habitual constipation.

Uses.—Wheat-flour is employed in medicine both as a therapeutical and a pharmaceutical agent.

It is used with great advantage as a dusting powder in burns and scalds. It cools the part, excludes the air, and absorbs the discharge, with which it forms a crust which effectually protects the subjacent part. When the crust has become detached by the accumulation of purulent matter beneath, a poultice may be applied, and, after the removal of the crust, the exposed surface may be again dusted over with flour.

A mixture of flour and water is used as a chemical antidote in poisoning by the salts of mercury, copper, zinc, silver, and tin, and by iodine (see vol. i. p. 203).

Flour is a constituent of some poultices, as the yeast-poultice (see ante, p. 86), and the mustard-poultice.

It is used in pharmacy for enveloping pills.

1. Amylum Tritici; Amylum; Wheat-Starch.—This starch was known to Pliny, who says the discovery of it was first made in Chios, and that it received its name amylum (ἀμύλον; from α, negative, and μύλος, a mill) because it was not prepared by grinding in a mill.

There are various modes of preparing it, but the method followed in this country is a mechanico-chemical one, the starch being separated from the other ingredients of wheat, partly by mechanical agency, and partly by chemical means. The cellulose or woody fibre of the grain is separated by mechanical means; the gum, sugar, albumen, and soluble salts, are dissolved out by cold water; and the gluten is got rid of partly by allowing it to undergo decomposition, and partly by solution in the acetic acid which is developed by fermentation.

A mixture of coarsely-grained wheat is steeped in water in a vat for one or two weeks (according to the state of the weather), by which acetic fermentation is established. The acid liquor (called sour water, or simply sours) is drawn off, and the impure starch washed on sieves to separate the bran. What passes through is received in shallow vessels termed frames. Here the starch is deposited. The sour liquor is again drawn off, and the slimes removed from the surface of the starch, which is to be again washed, strained, and allowed to deposit. The liquid which is drawn off is called green water. If the operation of washing be again resorted to, the part washed off is called white water instead of slimes, the liquid itself being still termed green water. When, by these processes, the starch has become sufficiently pure, it is boxed; that is, it is placed in wooden boxes perforated with holes and lined with canvas, where it drains. It is then cut in square lumps, placed on chalk stones or bricks, to absorb the moisture, and dried in a stove. By this pro-
cess the blocks are crusted (see ante, p. 108). The blocks are then scraped, papered, labelled, stamped, and returned to the stove. Here they split into columnar masses (like grain, tin, or basaltic columns), commonly called the race.

In commerce, there are two kinds of wheat-starch—one white; the other blue.

1. **White wheat-starch** is the sort which should be employed for dietetical or medicinal purposes. What is sold under the names of French starch and patent white starch is of this kind.

2. **Blue wheat-starch** is used by the laundress for stiffening linen. It owes its colour to finely-powdered smalt or indigo, which has been introduced into it before the boxing process. The Poland and glaze starches of the shops are of this kind. They are not adapted for medicinal purposes.

When examined by the microscope, wheat-starch is perceived to consist principally of large and small grains, with but few of intermediate size.1 They are not adapted for medicinal purposes.

When examined by the microscope, wheat-starch is perceived to consist principally of large and small grains, with but few of intermediate size. The smaller particles appear to be spheroidal or nearly so. The large ones are rounded, and flattened or lenticular. When at rest, they appear to be globular; but, by making them roll over in water, they are seen to be flattened, compressed, or lenticular; one of the flattened faces being sometimes a little more convex than the other. Viewed edgewise, the particles are strongly shaded. In the middle, or nearly so, of the flattened surface is the rounded, elongated, or slit hilum. This is surrounded by concentric rings, which extend frequently to the edge of the grains. When heated, the particles crack at the edges.

When heated in a tray in an oven to 300° F., wheat-starch acquires a buff colour, and is converted into dextrine or British gum.

Boiled in water, wheat-starch yields a mucilage, which, when sufficiently concentrated, forms, on cooling, a jelly (hydrate of starch). The consistence of this jelly is due to the mutual adhesion of the swollen hydrated integuments of the starch grains. When submitted to prolonged ebullition in a large quantity of water, the granule almost entirely dissolves, and the decoction, on cooling, does not gelatinize. With iodine the decoction, when cold, forms the blue iodide of starch, the colour of which is destroyed by alkalies and by heat.

The composition of wheat-starch is \( \text{C}_{12} \text{H}_{22} \text{O}_{11} \).

Wheat-starch is not employed alone as food. As found in commerce, its taste is somewhat disagreeable.

Starch powder is used as a dusting powder to absorb acrid secretions and to prevent exoration. Its decoction is used as an emollient and demulcent clyster in inflammatory conditions of the large intestines, and as a vehicle for the formation of other more active enemata. Starch is an antidote for poisoning by iodine, and is sometimes given in combination with this substance to prevent its local action (see vol. i. p. 405). It enters into the composition of the *Pulvis Tragacanthi compositus*, Ph. L.

2. **Decoctum Amyli, L.**; *Mucilago Amyli, E. D.*; *Decoction or Mucilage of Starch.*—(Starch 3iv; Water 2f [Oss, D.]) Rub the starch with the water gradually added, then boil for a short time.)—It is sometimes used alone as an enema in dysentery, irritation of the rectum, &c. It is a constituent of the Enema Opii, L.

3. **Furfures Tritici; Bran.**—Decoction or infusion of bran is sometimes employed as an emollient foot-bath. It is also taken internally as a demulcent in catarrhal affections. Its continued use causes a relaxed condition of bowels. Bran poul-

tices are applied warm in abdominal inflammation, spasms, &c. Bran bread is used in diabetes (see p. 127, foot-note).

4. FARINA TRITICI TOSTA; Baked Flour.—Wheat-flour lightly baked, so as to acquire a pale buff tint, is an excellent food for infants, invalids, and convalescents. Unlike the more amylaceous substances (such as arrow-root, tapioca, sago, &c.), it contains flesh- and blood-making as well as fat-making ingredients. Moreover, it has no tendency to relax the bowels; on the contrary, I think it is somewhat constipating. Hence, therefore, it may be used with advantage where there is a tendency to diarrhoea. When employed as an infant’s food, it may be sometimes desirable to mix it with a fourth of its weight of prepared barley-meal, to obviate its constipating effects. It is prepared by boiling it in milk or milk and water, and is taken as a kind of pottage or gruel.

Hard’s Farinaceous Food is a fine wheat-flour, which has been subjected to some heating process. It is an excellent preparation.

5. TURUNDUM ITALICUM; Macaroni, Vermicelli, and Italian or Cagliari Paste (in the form of stars, lentils, &c.).—These are pastes made with the finest and most glutinous wheat. By the artificial addition of wheat-gluten to the ordinary wheat, products may be obtained which rival the finest Italian pastes. The granulated gluten (gluten granulé) of MM. Véron frères is a paste made in this way. These various preparations are agreeable and most nourishing foods. Boiled in beef-tea, or similar fluids, they may be taken with great advantage by invalids and convalescents.

6. PANIS TRITICUS, L.; Wheaten Bread.—This is of two kinds, fermented or leavened, and unfermented or unleavened.

§. Panis fermentatus; Fermented or Leavened Bread.—The ingredients used in its manufacture are wheat-flour, salt, water, and yeast. In making the ordinary loaf-bread of London, the baker always employs a portion of potatoes; not for adulteration, but to assist fermentation, and to render the bread lighter. Patent yeast (see ante, p. 85) is generally employed by him on the score of economy. The yeast excites the fermentation of the sugar, which it converts into alcohol and carbonic acid; the former is dissipated in the oven, and the latter, distending the dough, causes it to rise, and gives the vesicular character to bread. During the process, a portion of starch is converted into soluble gum (dextrine) and a small portion of sugar.

The following table represents the comparative composition of the flour and bread of wheat, according to Vogel:—

Flour in baking takes up a considerable quantity of water, the absolute amount of which, however, depends on several circumstances. Home-made bread baked in separate tins contains about 44 per cent. of water, whereas the flour from which it is made contains only about 16 per cent. Ordinary bakers’ bread, baked in united loaves, contains as much as 50 or 51 per cent. of water. Various additions made to wheat-flour enable it to take up more water. Common salt does this: in the language of the baker it gives stiffness or strength to the dough. Alum (used by bakers under the name of “stuff”) has a similar effect: it also augments the whiteness and fineness of bread, and renders it less liable to crumble. It, therefore,

1 Payen, Précis de Chimie Industr. p. 397, 1819.
2 Quoted by Gmelin, Handb. d. Chem. Bd. ii. S. 1311 and 1313; also, Journ. de Pharm. t. iii. p. 211, 1817.
enables the baker to use an inferior flour with less chance of detection. Sulphate of copper (in the proportion of one grain to two pounds of flour) has a like effect, and has been used in some parts of Belgium to adulterate bread. It is said to enable the latter to take up 6 per cent. more water without appearing moist. 1

The general dietetical properties of bread resemble those of wheat-flour (see ante, p. 124). In diabetes, its use is objectionable on account of its augmenting the saccharinie condition of the urine. 2 In some forms of dyspepsia, fermented bread disagrees with the patient; and, in such, benefit is occasionally obtained by the substitution of unfermented bread. The use of brown bread as a preventive of habitual costiveness has already been referred to (see ante, p. 124). It, however, frequently fails to produce the desired effect.

Fermented bread is employed both in medicine and pharmacy. Crumb of bread (mica panis) is sometimes used in the formation of pills; but is objectionable for this purpose, on account of the pills thus made becoming excessively hard by keeping. Furthermore, in some cases, the constituents of Bread decompose the active ingredients of the pills. Thus, the chloride of sodium of bread decomposes nitrate of silver. Crumb of bread is most valuable for the preparation of poultices. The bread-and-water-poultice is prepared by covering some bread in a basin with hot water: after it has stood for ten minutes, pour off the excess of water, and spread the bread about one-third of an inch thick on soft linen, and apply to the affected part. Sometimes lint dipped in oil is applied beneath the poultice. 3 Decocotion of poppy, or Goulard's water, may be substituted for common water. This is a valuable application to phlegmonous inflammation. A bread-and-milk-poultice, to which lard is sometimes added, is also used to promote suppuration; but it should be frequently renewed, on account of its tendency to undergo decomposition. Both poultices are used in the treatment of irritable ulcers.

2. Panis sine fermento; Panis azymus; Unfermented Bread.—Of this there are two kinds; one compact and heavy, the other light and elastic.

Of the heavy and compact kind of unfermented bread we have an example in the common sea-biscuit or ship-bread (panis nauticus), which, on account of its hardness and compactness, must be more slowly permeated and acted on by the gastric juice than the ordinary light and porous fermented bread. These biscuits are frequently adulterated with chalk. Some dyspeptics prefer the lighter kinds of biscuits (panis bissecutus) to fermented bread. Biscuit powder is frequently used for infants’ food.

The light and porous kinds of unfermented bread owe their lightness and porosity to some volatile or gaseous body developed in the dough by either heat or chemical action. In the preparation of certain kinds of biscuits, solid sesquicarbonate of ammonia is used to produce lightness. The heat of the oven volatilizes the salt, the vapour of which distends the dough. Carbonic acid (developed by the action of an acid on an alkaline carbonate) is, however, the agent generally employed to give porosity to unfermented bread. The patent unfermented bread is a preparation of this kind. The following receipt yields an excellent product: Take of

---

1 For further details respecting the chemistry of fermented bread, the reader is referred to Dumais, Traité de Chimie appliquée aux Arts, t. vi., 1843; Johnstone’s Lectures on Agricultural Chemistry, 3d edit., 1847; and Payen, Précis de Chimie Industrielle, 1819.

2 Boucharlat (Comptes Rendus, Nov. 1847, p. 910) suggested the use of a gluten-bread, in diabetes, as a substitute for the ordinary wheaten-bread, but in practice it has not been found available. When quite devoid of starch, it can be masticated only with extreme difficulty, and, in fact, is not edible. —Bran-bread is, perhaps, the best kind of bread for diabetic patients. Dr. Prout (Stomach and Renal Diseases, 5th edit., p. 44, 1848) has published a receipt for a bread of this kind devised by his patient, the late Rev. J. Riggs. The following formula yields the best product which I have seen, and has proved highly useful in one case of diabetes: Take coarse wheat-bread; wash it thoroughly with water on a sieve, until the water passes through clearly; then dry it in an oven, and grind to a fine powder by a mill (the mill which was found to answer was made by White, in Holborn). Then take 7 eggs, 1 pint of milk, 1 lb. of butter, a few caraway seeds, or some ginger, and make into a paste with a sufficiency of the bran-flour. Divide the mass into seven equal parts, and bake each separately, in a saucepan, by rather a quick oven; the time required for baking is usually about 30 minutes. —Dr. Percy (Chemical Gazette, March 15, 1848) has published a receipt for a bread for diabetic patients made of the liguineous matter of potatoes (see the article Solanum tuberosum).

Flour ½ lb; Bicarbonate of Soda 40 grains; Cold Water half a pint, or as much as may be sufficient; Muratic Acid of the shops 60 drops; Powdered White Sugar a teaspoonful. Intimately mix the bicarbonate of soda and sugar with the flour, in a large basin, by means of a wooden spoon. Then gradually add the water with which the acid has been previously mixed, stirring constantly, so as to form an intimate mixture very speedily. Divide into two loaves, and immediately put them into a quick oven.—If any soda should escape the action of the acid, it causes one or more yellow spots, which, however, are more unsightly than detrimental. The sugar may be omitted if thought desirable. This kind of bread is well adapted for the use of invalids and dyspeptics. With the latter it sometimes agrees when ordinary fermented bread fails. It is superior to biscuits in lightness and porosity. It is a very convenient kind of bread for persons on ship-board and in other places where yeast cannot be procured.

38. SECALE CEREALE, Linn. — COMMON RYE.

Description.—Rye is mentioned in the English version of the Old Testament; but, in the opinion of Sprengel, spelt wheat is meant. The same writer also states that Theophrastus is the earliest author who notices the Secale cereale; but the word spelt, used by Theophrastus, is thought by Fraas to refer to Triticum monococcum, and not to rye. Galen mentions rye under the name of $\beta$πις, the term by which, as well as by σικαλης, rye is known in modern Greece. Pliny speaks of secale or rye.

Botany. Gen. Char.—Spikelets two-flowered. Flores sessile, distichous, with the linear rudiment of a third terminal one. Glumes two, herbaceous, keeled, nearly opposite, awnless or awned. Paleae two, herbaceous; the lower one awned at the point, keeled, unequal sided, broadest and thickest on the outer side; the upper shorter and bincarinate. Stamina three. Ovarium pyriform, hairy. Stigmas two, nearly sessile, terminal, feathery, with long, simple, finely-toothed hairs. Scales two, entire, ciliate. Caryopsis hairy at the point, loose (Kunth).

Sp. Char.—Glumes and awns seaborous (Kunth).

Hab.—The Caucasian-Caspian desert. Cultivated in Europe; but little in England; frequently on the Continent.

In the shops are sold powders under various names (such as Borweich's Original German Baking Powder for Making Bread without Yeast; and Edward's Egg Powder) to enable persons to prepare a light bread without yeast, or even light puddings without eggs. They are usually mixtures of tartaric acid and carbonates of soda, with some farinaceous substance (when flour and potato starch); to which is sometimes added a small portion of alum. They are very useful and convenient preparations; and, for employment on board ship, and in various other situations, will be found very valuable.

1 The above formula yields a bread of excellent quality, as I can vouch from having repeatedly employed it. Various other formulæ have been published, many of which doubtless also yield excellent products. The following are given in a little pamphlet entitled Instructions for making Unfermented Bread, by a Physician, 15th edit. 1848:—

COMMON RYE:—DESCRIPTION; COMPOSITION.

smaller and darker externally. Internally they are white and farinaceous; externally brownish. Like wheat, as found in commerce, they are devoid of their husk or palea.

In order that the changes which rye undergoes when it becomes ergotized may be better understood, Corda* has given the following description of the microscopic characters of healthy rye grains: "When we submit a thin transverse section of a healthy grain of rye to microscopic examination, we perceive that the seed-coat (Fig. 207, a) consists of three layers of thick-walled cells, beneath which we find the second, properly the third, seed-coat (207, b), composed of a single layer of thick-walled cells, having scarcely any cavity. Next follows a layer of cells containing gluten (207, c); and afterwards the cellular tissue of the albumen (207, d). This consists of large roundish hexagonal cells, which contain grains of starch (Fig. 208). The starch-grains (Fig. 209) are roundish or ellipsoidal, and about the 0.000150 of the Paris line in length."

**Fig. 207.** A thin section of a ripe grain of rye. a, seed-coat; b, inner seed-coat; c, layer of gluten cells; d, cells of the albumen filled with starch grains.

**Fig. 208.** A single cell of the albumen more highly magnified, and showing the starch grains with which it is filled.

**Fig. 209.** Grains of rye starch very highly magnified (according to Corda).

COMPOSITION.—Rye has been analyzed by Einhof,° by Boussingault,* by Fuerstenberg,* and by Payen (see ante, p. 106). The proportion of starch and proteine compounds contained in it, as ascertained by Krocker and Horsfeld, have been before stated (see ante, vol. i. p. 119).

1 Beitrag zur Kenntiss der Brandarten der Cerealien und des Mutterkorns, in the Oekonomische Neigkeiten und Verhandlungen, No. 83, Vienna, 1849.
3 Quoted by Johnston, Lectures on Agricultural Chemistry. 
VEGETABLES.—NAT. ORD. GRAMINEÆ.

The composition of the ashes of rye is stated at p. 106.

1. **Protein Compounds.** *Fibrine, Glutin, and Albumen.*—The so-called gluten of rye differs from wheat-gluten. It is not cohesive, and is soluble in water and alcohol; but after it has been dissolved in alcohol it is insoluble in water. It agrees in its properties with the glutin of wheat (see vol. i. p. 116, and ante, p. 100). **Heldt** considers it to be identical in composition with the other protein compounds of rye analyzed by Dr. Bence Jones and Scheerer.

2. **Starch.** The starch of rye, like that of wheat, consists principally of large and small grains, with but few of intermediate size; the larger ones being, on the whole, somewhat larger than the corresponding ones of wheat. The shape of the larger grains is circular, flat, or lenticular, of the smaller ones globular (chiefly), ellipsoidal or ovoidal, rarely angular or mullar-shaped. On the flattened surface of the larger grains is seen the central, rarely circular, usually slit, or 3-, 4-, or even 5- radiate hilum, sometimes surrounded by very faint concentric rings and delicate radiating lines. By polarized light the grains show a central cross.

**Chemical Characteristics.**—A cold decoction of rye forms with iodic acid the blue iodide of starch. By washing rye-dough with water, nearly the whole becomes diffused through the liquid, little more than husk or bran remaining behind. The milky liquid deposits on standing starch grains, and the decanted portion yields on evaporation the so-called gluten; from which, sugar is extracted by water, and oil by ether: the residue (glutin) is soluble in alcohol.

**Physiological Effects.**—In its nutritive qualities rye resembles wheat, especially in the fitness of its flour for making bread; but it contains less proteine matter and more sugar.

**Uses.**—Rye is employed dietetically and medicinally; and also in the distillery and brewery.

Rye-bread (in Germany called *Schwartzbrot* or *black bread*) is in common use among the inhabitants of the northern parts of Europe, but in this country is rarely employed. It is said to be more laxative (especially to those unaccustomed to its use) than wheat-bread; and hence is sometimes taken to counteract habitual constipation. The roasted seeds (semina secalis tosta) have been employed as a substitute for coffee. On the continent rye-flour and rye-bran are applied to the same medicinal uses that wheat-flour and wheat-bran are applied in England. Rye pottage (*pullentum vel jusculum secalinum*) is said to be a useful article of diet in consumptive cases.

39. **SECALE CORNUTUM.**—**Spurred Rye or Ergot.**

**Ergota.**—Secale cereale semen purgo parasitico corruptum? *L.* The ergot, a peculiar excrecence supposed to be produced by a parasitical fungus, *D.*

**Synonyms.**—*Clavi siliginis, Lonicerus; Secalis mater, Thalius; Secale luxurians, Bauhin, Pinax, lib. i. sect. iv. p. 23; Grana secalis degenerati, Brunner; Secale cornutum, Baldinger; Clavus secalis vel secalinus; Secale maternum, turgidum vel temulentum; Ergota, Ph. Lond. et Ed.; Spur; Spurred or horned Rye; Ergot of Rye; Cockspur Rye; Cockspur.

**History.**—No undoubted reference to ergot is found in the writings of the ancients. The disease produced by it is supposed to be referred to in the following passage: "1089. A pestilent year, especially in the western parts of Lorraine, where many persons became putrid, in consequence of their inward parts being consumed by St. Anthony's fire. Their limbs were rotten, and became black like coal. They either perished miserably, or, deprived of their putrid hands and feet, were reserved for a more miserable life. Moreover, many cripples were afflicted with contraction of the sinews [nervorum contractio].***

---

2 The following measurements of eight (including the largest and smallest) grains of rye starch were made by Mr. George Jackson: —
3 Pearson, Prac. Synop. of the Mat. Ailim. 91.
4 Extract from the works of Siegbert, in the Recueil des Histor. des Gauls et de la France, tom. xiiii. p. 269. A passage somewhat similar to the above, with the addition of the following, "the bread which
The first botanical writer who notices ergot is Lonicerus. It seems to have been employed by women to promote labour pains long before its powers were known to the profession. Camerarius, in 1683, mentions that it was a popular remedy in Germany for accelerating parturition. In Italy and France, also, it appears to have been long in use.

Botany.—The nature and formation of ergot are subjects on which botanists have been much divided in opinion.

1. Some regard ergot as a fungus growing between the glumes of grasses in the place of the ovary.—Otto von Münsthausen, Schrank, De Candolle, Fries, Wiggers, and formerly Berkeley, adopted this opinion, and described ergot as a fungus under the name of Spermoedia Clavus, Fries (Clavaria Clavus, Münch.; Sclerotium Clavus, De Cand.). Fries and Berkeley, however, evidently entertained some doubts respecting its nature; for the first suggests that the genus Spermoedia consists of "semina graminum morbosa," and the second says, "it appears to be only a diseased state of the grain, and has scarcely sufficient claim to be admitted among fungi as a distinct genus." The latest writer who has adopted this view is Guibourt, who concludes that ergot is not an ovary or altered grain, but a fungus which, after the destruction of the ovary, is grafted in its place on the pedicel. Against this opinion, Wiggers may be urged the circumstance noticed by Tessier, that a part only of the grain may be ergotized. Moreover, the scales of the base of the ergot, the frequent remains of the stigma on its top, and the articulation of it to the receptacle, prove that it is not an independent fungus, but an altered grain.

2. Some regard ergot as a diseased condition of the ovary or seed.—The arguments adduced against the last opinion are in favour of the present one. Though a considerable number of writers have taken this view of the nature of ergot, there has been great discordance among them as to the causes which produced the disease.

(a) Some have supposed that ordinary morbid causes (such as moisture combined with warmth) were sufficient to give rise to this diseased condition of the grain. Tessier and Willdenow appear to have been of this opinion.

(b) Some have ascribed the disease to the attack of insects or other animals. Tallet, Fontana, Réaup, and Field, supported this view, which may, I may add, has subsequently been satisfactorily disproved.

γ. Some, dissatisfied with the previously assigned causes of the disease, have been content with declaring ergot to be a disease, but without specifying the circumstances which induce it. Mr. Bauer, who closely watched the development of ergot during eight years (1805-13), and has made some beautiful drawings of it in different stages, arrived at this conclusion; as also Phæbus.

3. Others have referred the production of the disease to the presence of a parasitic fungus. This opinion, which appears to me to be the correct one, and which must not be confounded with that of Itt (Mycol., ii. 509), has been adopted and supported by Léveillé in 1826, by Durtrochet, by Mr. John Smith, and by the late Mr. Edwin Quckett, and more recently by Férès and by Corda. But though the writers just mentioned agree in

was eaten at this period was remarkable for its deep violet colour, is quoted by Bayle (Biblioth. Thérap. tom. iii. p. 374) from Mezeray, Abrégé Chronologique. But I cannot find the passage in the first and best edition of Mezeray's Abrégé Chron. 3 vols. 4to. 1665; or in his Histoire de France; or in his Mémoires Hist. et Critiques. Whether or not it be in the second and less perfect edition of Mezeray's Abrégé Chronologique, I am unable to decide, not having seen this work.

1 The etymology of the word ergot is very doubtful. Whiter (Etymologicon Universalis, ii. 504) thinks that it is derived from arguo, and is attached to such terms as urgo. It was anciently written argot.

17 Ann. de la Soc. Linn. de Paris.

21 Beitrag zur Kenntniss der Brandarien der Cerealien und des Mutterkorns, in der Oekonomischen Neuigkeiten und Verhandlungen, No. 83, published at Vienna, 1846.
considering ergot to be a disease of the ovary or seed, caused by a parasitic fungus, considerable difference exists among them as to the real nature of the parasite.¹

The statements of Léveillé, Phillipar,² Smith, and Quekett, leave, I think, but little doubt that ergot is a disease of the grain caused by the presence of a parasitical fungus. This view is supported by the observations of Wiggers, that the white dust (sporidia, Quek.) found on the surface of ergot will produce the disease in any plant (grass?) if sprinkled in the soil at its roots. Mr. Quekett (see ante, p. 87) infected grains of corn by immersing them in water in which the sporidia of the Oidium abortificaciens were contained. The plants which were produced by the germination of the grains were all ergotized.

Mr. Quekett, who most carefully examined the development of ergot, says that the first appearance of the ergot is observed by the young grain and its appendages becoming covered with a white coating composed of multitudes of sporidia (Fig. 184 A, p. 87) mixed with minute cobweb-like filaments (Oidium abortificaciens, Fig. 184, H 1, p. 87). This coating extends over all the other parts of the grain, cements the anthers and stigmas together, and gives the whole a mildewed appearance. When the grain is immersed in water, the sporidia fall to the bottom of the liquid. A sweet fluid—at first limpid, afterwards viscid—is found in the affected flower at this stage; and, when examined by the microscope, is found to contain the sporidia just referred to (Phillipar, Smith, Quekett). Phillipar says this fluid oozes from the floral centre; and Mr. Quekett, who at first thought that it had an external origin, was subsequently convinced that it escaped from the ergot or the parts around it.

If we examine the ergot when about half-grown (Fig. 210), we find it just beginning to show itself above the paleæ, and presenting a purplish-black colour. By

![Ergot of Rye](Fig. 210)

A. A side view of a longitudinal section of an infected grain, soon after fecundation, when the disease makes its first external appearance: magnified eight times in diameter.
B. Front view of a section of the above infected grain, cut at letter a: magnified sixteen times in diameter.
C. Ditto, cut at letter b: magnified sixteen times in diameter.
D. Side view of an unripe but advanced ergotized grain, at the upper part of which is the tuberculated portion, having a vermiciform appearance, and constituting the fungus (Sphaecilia Segetum) of Léveillé.
E. Longitudinal section of the grain.
F. A full-grown ergot, within its floret, magnified twice its diameter.

¹ I have given an abstract of M. Péo's opinion in the Pharmaceutical Journal, vol. v. p. 282.
this time it has lost in part its white coating, and the production of sporidia and filaments has nearly ceased. At the upper portion of the grain, the coating now presents a vermiciform appearance, which Léveillé describes as constituting cerebriform undulations. These are beautifully depicted in Mr. Bauer’s drawings (Fig. 210, A D E). Léveillé regards this terminal tubercle of the grain as a parasitical fungus, which he calls the Sphacelium Setatum. But these undulations are merely masses of sporidia; for if a little be scraped off with a knife, then moistened, and examined by the microscope, we find nothing but myriads of sporidia. The ergot now increases in a very rapid manner.

Corda has confirmed the observations of Messrs. Smith and Quekett; but, as I have already stated (see ante, p. 87), he considers the fungus to be a new species of Hymenula (of the sub-order Hymenophycetes), to which he has given the name of H. clavus.

To the agriculturist, an important subject of inquiry is the predisposing causes of ergot. Very little of a satisfactory nature has, however, been ascertained on this point. One fact, indeed, seems to have been fully established—viz. that moisture, which was formerly thought to be the fertile source of the spur, has little, if anything, to do with it. Moreover, the disease is not peculiar to rye. Many other grasses (Phoebus has enumerated 31 species) are subject to it. In the summer of 1838, I found the following grasses, growing in Greenwich marshes, ergotized: Lolium perenne, Dactylis glomerata, Alopecurus pratensis, Festuca pratensis, Triticum repens, Arundinaphyriges, Hordeum murinum, and H. pratense. Professor Henslow found it in wheat which had been sent to the miller. I am indebted to him also for fine specimens of ergot on Anemopphila arundinacea. But the disease is not confined to the Gramineae: the Cyperaceae are also subject to it, and perhaps, likewise, Palmaceae.

COMMERCIAL—Ergot is imported from Germany, France, and America. The late

---

1 Quoted by Richard, Elem. d’Hist. Nat. i. 332.
2 Phillipar, op. cit. 125; also, Bauer, MSS.
4 Phoebus, op. cit. 105.
Mr. Butler, of Covent Garden Market, told me that about 1 3/4 tons were imported in the year 1839.

Description.—When we examine a number of ears of ergotized rye, we find that the number of grains in each spike which have become ergotized varies considerably: there may be one only, or the spike may be covered with them. Usually, the number is from three to ten.

The mature ergot (Fig. 211) projects considerably beyond the paleae. It has a violet-black colour, and presents scarcely any filaments and sporidia.

The spurred rye, or ergot (ergotica) of commerce, consists of grains which vary in length from a few lines to an inch, or even an inch and a half, and whose breadth is from half a line to four lines. Their form is cylindrical or obscurely triangular, with obtuse angles, tapering at the extremities (fusiform), curved like the spur of a cock, unequally furrowed on two sides, often irregularly cracked and fissured. The odour of a single grain is not detectable, but of a large quantity is fishy, peculiar, and nauseous. The taste is not very marked, but is disagreeable, and very slightly acid. The grains are externally purplish-brown or black, more or less covered by a bloom, moderately brittle, the fractured surface being tolerably smooth, and whitish or purplish-white. Their sp. gr. is somewhat greater than that of water, though, when thrown into this liquid, they usually float at first, owing to the adherent air. The lower part of the grain is sometimes heavier than the upper.

When examined by the microscope, we find that the ergot consists of three distinct parts:—

1. The internal part or body of the ergot: this is composed of the hexagonal or rounded cellular tissue. The cells have the shape and regularity of the normal cells of the albumen, but they are considerably smaller (Corda says they are only 1/40th of the size), and contain, instead of starch, from one to three globules of oil, which are lighter than water and soluble in ether (Fig. 212, d, and 214). If the structure of ergot be examined after the grains have been dried and re-moistened, the tissue presents a very irregular appearance.

2. The violet or blackish coat of the ergot: this consists of a layer of longitudinally elongated delicate cells (see Fig. 212, c).

3. The bloom, which to a greater or less extent, covers the violet coat of the ergot: it resembles the bloom of plums, and may be readily wiped off. According to the late Mr. Quekett, it consists of the sporidia of the Oidium

*Phillipar, op. cit. p. 96.*
SPURRED RYE OR ERGOT:—DESCRIPTION; COMPOSITION.

**abortis faciens** (Fig. 184, A). But Corda describes it as consisting of two parts: a layer of cylindrical, undivided cells (sporophores or basidia, Fig. 212, b), supporting the spores (Fig. 212, a, and Fig. 213).

In considering the metamorphosis of the normal rye grains have undergone by becoming ergotized, it appears that the seed coats and gluten cells (Fig. 206, a b c, p. 129) have been replaced by a layer of dark cells (Fig. 212, c); that the large cells of the albumen (Fig. 207, d, and Fig. 208, p. 129) have been replaced by the small cells of the ergot (Figs. 212 d, and 214); that the starch grains of the cells of the albumen (Fig. 208, and Fig. 209) have been replaced by drops of oil in the cells of the ergot (Fig. 212, d, and Fig. 214); and that the little body at the top of the ergot (Fig. 210, F a), which Phoebus calls the Mützchen, is the remains of the hairy crown of the grain, of the stigmata, and of the withered elevated pericarp.

Thus the entire organization of the grains is changed, and at the same time their effects on the animal body are altered; for while sound rye is edible, nutritious, and healthy, ergotized rye is unwholesome and poisonous, producing raphania and abortion.

**Deterioration.**—The ergot of rye is fed on by a little acarus, which is about one-fourth of the size of a cheese-mite. This animal destroys the interior of the ergot, and leaves the grain as a mere shell. It produces much powdery excrementitious matter (Quckett). In four months 7½ ounces of this fecal matter of the acarus were formed in seven pounds of ergot. I have some ergot which has been kept for eleven years in a stoppered glass vessel without being attacked by the acarus, and it has all the characteristics of good ergot. It is advisable, however, not to use ergot which has been kept for more than two years.

**Composition.**—Ergot was analyzed, in 1816, by Vauquelin; 4 in 1817, by Pettenkofer; 2 in 1826, by Winkler; 2 in 1829, by Maas; 4 in 1831, by Wiggers; 3 and more recently by Chevallier. 6 The results obtained by Chevallier were analogous to those of Wiggers.

1 Ergotin was procured by digesting ergot with ether, to remove the fatty matter, and then in boiling alcohol. The alcoholic solution was evaporated, and the extract treated by water. The ergot remained undissolved. It was brownish-red, with an acrid bitter taste, and, when warmed, had a peculiar but unpleasant odour. It was soluble in alcohol, but insoluble in water or ether. It is probable, therefore, that it is a resinoid colouring matter. It proved fatal to a hen. Nine grains of it were equal to an ounce and a half of ergot. It appears, then, that though a poisonous principle, it is probably not the agent which acts on the uterus, for the latter is soluble in water, whereas ergotin is not. It is possible, however, that it may be rendered soluble in water by combination with some other body.

2 Oil or Ergot.—As this is now used in medicine, its properties will be described hereafter (see p. 143).

There are no good grounds for suspecting the existence of either hydrocyanic acid or phosphate of morphia in ergot, as supposed by Pettenkofer.

4 Huchner’s Repert. lii. 95.
CHEMICAL CHARACTERISTICS.—Ergot is inflammable, burning with a clear yellowish white flame. The aqueous infusion or decoction of ergot is red, and possesses acid properties. Both acetate and diacetate of lead cause precipitates in a decoction of ergot. Iodine gives no indication of the presence of starch. Nitrate of silver causes a copious precipitate soluble in ammonia, but insoluble in nitric acid. Tincture of nutgalls also produces a precipitate, (tannate of ergotin?) Alkalies heighten the red colour of the decoction.

PHYSIOLOGICAL EFFECTS.—Great discrepancy is to be found in the accounts published respecting the influence of spurred rye on man and animals. While the majority of experimenters or practical observers concur in assigning to it energetic powers, others have declared it harmless.

a. On Vegetables.—Schübler and Zeller have tried its effects on plants, and I infer from their statements that they found it poisonous.1

b. On Animals.—Accidental observation and direct experiment concur in showing that in most instances spurred rye acts as a poison to the animal economy. But, as Phæbus correctly observes, we cannot call it a violent poison, since draughts and even ounces are required to destroy small animals (e. g. rabbits and pigeons).

It has proved poisonous to flies, leeches, birds (geese, ducks, pigeons, common fowls, &c.), and mammals, (dogs, cats, pigs, sheep, rabbits, &c.) Birds and mammals refuse to take it, even mixed with other kinds of food. Dier2 gives the following as the symptoms produced by it in dogs who are compelled to swallow it: "Great aversion to it, discharge of saliva and mucus from the mouth, vomiting, dilatation of the pupil, quickened respiration and circulation, frequent moanings, trembling of the body, continual running round, staggering gait, semi-paralysis of the extremities, especially the hinder ones, sometimes diarrhœa; sometimes hot anus, increased formation of gas in the alimentary canal; faintness and sleepiness, with great thirst, but diminished appetite. Death followed under gradually increasing feebleness, without being preceded by convulsions. To the less constant symptoms belong inflammation of the conjunctiva, and the peculiar appearance of turning round in a circle from right to left." Similar observations as to its injurious operation have been made by Robert.3 In some cases abscess and gangrene of various parts of the body, with dropping off of the toes, and convulsions, have been noticed. A strong decoction injected into the vein of a dog caused general feebleness, paralysis of the posterior extremities, vomiting, and death.4

But there are not wanting cases apparently showing that spurred rye has no injurious action on animals. The most remarkable and striking are those related by Block.5 In 1811, twenty sheep ate together nine pounds of it daily for four weeks without any ill effects. In another instance, twenty sheep consumed thirteen pounds and a half daily, for two months, without injury. Thirty cows took together twenty-seven pounds daily, for three months, with impunity; and two fat cows took, in addition, nine pounds of ergot daily, with no other obvious effect than that their milk gave a bad caseous cream, which did not yield good butter. These statements furnish another proof to the toxicologist that the ruminants suffer less from vegetable poisons than other animals.

Another interesting topic of inquiry is the action of ergot on the gravid uterus of mammals. Chapman6 says "it never fails, in a short time, to occasion abortion." We have the testimony of Percy and Laurent, that a decoction injected into the veins of a cow caused the animal to calve speedily; and in one out of three experiments, Mr. Combes has stated, the ergot caused the abortion of a bitch.7 Dier8 found that it caused uterine contractions in dogs, rabbits, and sows. Large doses given to bitches induced an inflammatory condition of the uterus, and destroyed both mother and her young. However, in opposition to these statements, we have

the evidence of Chatard, Warner, Villeneuve, and others, who failed in producing abortion with it.¹

I am indebted to the late Mr. Youatt, formerly Veterinary Surgeon to the Zoological Society, for the following note respecting the effects of ergot on animals:—

"I have, for the last six or seven years, been in the habit of administering the ergot of rye to quadrupeds in cases of difficult or protracted parturition, in order to stimulate the uterus to renewed or increased action. In the monogastric, if I may venture to use the term, I have never known it fail of producing considerable effect, even when the uterus has been previously exhausted by continued and violent efforts. In the ruminant, with its compound stomach or stomachs, I have witnessed many a case of its successful exhibition. I have had recourse to it in the cow, the sheep, and the deer, both foreign and domestic. Parturition has not always been accomplished, from false presentations or other causes, but the uterus has in every case responded—it has been roused to a greater or less degree of renewed action. On the other hand, there are cases recorded by veterinary practitioners, in which it has been given in very large quantities without producing the slightest effect. I have always attributed this to a certain degree of forgetfulness of the construction of the stomachs of ruminants. If the medicine, as is too often the case, is poured hastily down, and from a large vessel, it breaks through the floor of the oesophagean canal and falls into the rumen, and there it remains perfectly inert. But if it is suffered to trickle down the oesophagean canal, although a portion of it may still enter the rumen, the greater part will flow on through the oesophagean canal and the many-villous stomach, and produce the desired effect."

γ: On Man.—These may be noticed under two heads: 1, effects of single doses; 2, effects of its continued use as an article of food.

1. In single or few doses.—Hertwig,² Lorinser,³ Jörg,⁴ and Diez,⁵ who have endeavoured to ascertain the effects of ergot by experiment, agree in stating that, in doses of from half a drachm to two drachms, nausea, inclination to vomit, dryness of the throat, great thirst, aversion to food, uneasiness or actual pain in the abdomen, occasionally alvine evacuations, weight and pain in the head, giddiness, in some cases stupor and dilatation of pupils, have resulted from its use. It deserves, however, to be noticed, that these effects have not been observed by some experimenters.⁶

The effects produced by the use of single or a few doses of ergot may be conveniently arranged under four heads.

a. Effects on the uterine system. (Uterine contractions.)—The action of spurred rye on the uterus, when labour has actually commenced, is usually observed in from ten to twenty minutes after the medicine has been taken, and is manifested by an increase in the violence, the continuance, and the frequency of the pains, which usually never cease until the child is born; nay, they often continue for some minutes after, and promote the speedy separation of the placenta and the firm contraction of the uterus in a globular form. The contractions and pains caused by ergot are distinguished from those of natural labour by their continuance; scarcely any interval can be perceived between them, but a sensation is experienced of one continued forcing effort. If, from any mechanical impediment (as distortion), the uterus cannot get rid of its contents, the violence of its contraction may cause its rupture, as in the cases alluded to by Dr. Merriman,⁷ Mr. Armstrong,⁸ and Mr. Coward.⁹

Ergot sometimes fails to excite uterine contractions. The causes of failure are, for the most part, conjectural. The quality of the ergot, peculiarities on the part

⁷ Sundelin, Heilmittell. i. 513, 3te Aufs.
of the mother, and death of the foetus, have been assigned as such. The two first will be readily admitted; but why the remedy should be altogether inert "where the foetus has been for some time dead, and putrefaction to any extent taken place," cannot be readily explained. Its occasional failure has been urged by the late Dr. Hamilton as an argument in favour of his notion that ergot acts "in no other way than by influencing the imagination." But, on the same ground, the sialagogue power of mercury might be denied. Dr. Hamilton's erroneous estimate of the powers of ergot is referable to a want of experience of its use; for he admits that he has only had two opportunities in practice of making a fair trial of it.

There is usually much less hemorrhage after delivery, when ergot has been employed, than where it has not been exhibited. The lochial discharges are also said to be less; but this is certainly not constantly the case. Moreover, it has been asserted "that the menstrual discharge has not recurred after the use of the ergot in certain cases of protracted parturition." But the inference intended to be conveyed here, viz., that ergot caused the non-recurrence, is not correct; at least, I am acquainted with several cases in which this effect did not follow the employment of spurred rye, and I know of none in which it did.

Ergot has been charged with causing the death of the child; but the charge has been repelled by some experienced practitioners as being devoid of the least foundation. "The ergot," says Dr. Hosack, "has been called, in some of the books, from its effects in hastening labour, the *pullis ad partum*; as it regards the child, it may, with almost equal truth, be denominated the *pullis ad mortem*; for I believe its operation, when sufficient to expel the child, in cases where nature is alone unequal to the task, is to produce so violent a contraction of the womb, and consequent convolution and compression of the uterine vessels as very much to impede, if not totally to interrupt, the circulation between the mother and child." However, Dr. Chapman strongly denies this charge, and tells us that in 200 cases which occurred in the practice of himself and Drs. Dewees and James, the ergot was used without doing harm in any respect; and, he adds, "no one here believes in the alleged deleterious influence of the article on the foetus." It is not improbable, however, where the impediment to labour is very great, that the violent action of the uterus may be attended with the result stated by Dr. Hosack. Dr. F. H. Ramsbotham has suggested that the poisonous influence of ergot may be extended from the mother to the foetus, as in the case of opium. He also states that of 36 cases in which he induced premature labour by puncturating the membranes, 21 children were born alive; while, in 26 cases of premature labour induced by ergot only, 12 children only were born alive. This fact strongly favours the notion of the deleterious influence of the ergot on the foetus.

Given to excite abortion, or premature labour, ergot has sometimes failed to produce the desired effect. Hence, many experienced accoucheurs have concluded that, for this medicine to have any effect on the uterus, it was necessary that the process of labour should have actually commenced. But, while we admit that it sometimes fails, we have abundant evidence to prove that it frequently succeeds; and most practitioners, I think, are now satisfied that in a large number of cases it has the power of originating the process of accouchemen. Cases illustrating its power in this respect are referred to by Bayle; and others are mentioned by Waller, Holmes, Ramsbotham, Müller, and others.

The action of ergot on the unimpressed uterus is manifested by painful contractions, frequently denominated "bearing-down pains," and by the obvious

---

1. Dr. Bibby, in Mettriman's Synopsis, p. 198.
influence which it exercises over various morbid conditions of this viscus; more particularly by its checking uterine hemorrhage, and expelling polypous masses. Tenderness of the uterus, and even actual metritis, are said to have been induced by it.

3. Effects on the Cerebro-Spinal System. (Narcotism).—Weight and pain in the head, giddiness, delirium, dilatation of pupil, and stupor, are the principal symptoms which indicate the action of ergot of rye on the brain. Dr. Maußell has published five cases (viz., two which occurred to Dr. Churchill, one to Dr. Johnson, and two to Dr. Cusack), in which delirium or stupor resulted from the use of ergot (in half-drachm and two-drachm doses), and was accompanied by great depression of pulse. Trousseau and Pidoux found that under the repeated use of ergot, dilatation of pupil was the most common symptom of cerebral disorder. It began to be obvious in from twelve to twenty-four hours after the commencement of the use of the medicine, and sometimes continued for several days after its cessation. The cerebral disorder is frequently preceded by the uterine contractions, and usually remains for some time after these have subsided.

Effects of ergot on the Circulatory System.—I have known increased frequency and fulness of pulse, copious perspiration, and flushed countenance, follow the use of ergot during parturition. But in most instances the opposite effect has been induced; the patient has experienced great faintness, the pulse has been greatly diminished in both frequency and fulness, and the face has become pale or livid. In one case, mentioned by Dr. Cusack, the pulse was reduced from 120 to 90. Dr. Maußell has referred to four other cases. These effects on the circulatory system were accompanied with cerebral disorder, of which they were probably consequences. Similar observations, as to the power of ergot to diminish the frequency of the pulse, have been noticed by others.

8. Other effects of ergot.—Nausea and vomiting are not uncommon consequences of the exhibition of ergot when the stomach is in an irritatable condition. Various other symptoms have been ascribed to the use of ergot; such as weariness of the limbs and itching of the skin.

2. Effects produced by the continued use of ergot as an article of food (Ergotism, Fr.; Raphania, Linn., Vog., Cull., Good; Convulsio raphania, and Eclampsia typhodes, Sauv.; Morbus spasmodicus, Rothm.; Morbus convulsivus, maliginus, epidemicus, cerealis, &c., Alt.; Kriebelkrankheit, or the creeping sickness, Germ.).—Different parts of the continent, e.g. France (especially in the district of Sologne), Silesia, Prussia, Bohemia, Saxony, Denmark, Switzerland, and Sweden, have been, at various periods, visited with a dangerous epidemic (known by the names above mentioned), which affected, at the same time, whole districts of country, attacking persons of both sexes and of all ages. So long back as 1597 (Tissot), the use of ergotized rye was thought to be the cause of it. Various circumstances have appeared to prove the correctness of this opinion, which has been further confirmed by the effects of ergot on animals, as well as by the occurrence of a disease similar to, if not identical with, ergotism, in consequence of the use of damaged wheat. Yet several intelligent writers have not acquiesced in this view; and the circumstances mentioned by Trousseau, and by Dr. Hamilton, are certainly calculated to throw some doubts over the usually received opinion.

Ergotism assumes two types; the one of which has been denominated the convulsive, the other the gangrenous ergotism. Whether these arise from different conditions of the ergot, or from peculiarities on the part of the patient, or from the

9. Phil. Trans. for 1702; Henslow, op. supra cit.
different quantity of the ergot taken, we are hardly prepared now to say. In convulsive ergotism, the symptoms are weariness, giddiness, contraction of the muscles of the extremities, formation, diunness of sight, loss of sensibility, voracious appetite, yellow countenance, and convulsions, followed by death. In the gangrenous ergotism there is also experienced formication; that is, a feeling as if insects were creeping over the skin, voracious appetite, coldness and insensibility of the extremities, followed by gangrene.4

Uses.—To Dr. Stearns, of the United States, is due the credit of introducing ergot of rye to the notice of the profession as an agent specifically exciting uterine contractions.5 In 1814, a paper was published by Mr. Prescott,6 on the effects of it in exciting labour-pains, and in uterine hemorrhage. It was not employed in England until 1824. The following are the principal uses of it:—

1. To increase the expulsatory efforts of the womb in protracted or lingering labours.—When the delay of delivery is ascribable solely to the feeble contractions of the uterus, ergot is admissible, provided, first, that there be a proper conformation of the pelvis and soft parts; secondly, that the os uteri, vagina, and os externum, be dilated, or readily dilatable, and lubricated with a sufficient secretion; and, lastly, that the child be presenting naturally, or so that it shall form no great mechanical impediment to delivery. A natural position of the head is not an absolute essential for the use of ergot, since this medicine is admissible in some cases of breech presentation. The circumstances which especially contraindicate or preclude the use of this medicine are those which create an unusual resistance to the passage of the child: such are, disproportion between the size of the head and of the pelvis, great rigidity of the soft parts, and extraneous growths. Moreover, "earliness of the stage" of labour is laid down by Dr. Bigelow7 as a circumstance contraindicating the use of ergot. The proper period for its exhibition is when the head of the child has passed the brim of the pelvis. Some practitioners assert that a dilated or lax condition of the os uteri is not an essential requisite for the exhibition of ergot. It has been contended that one of the valuable properties of this medicine is to cause the dilatation of the uterine orifice; and cases are not wanting to confirm these statements.8

2. To hasten delivery when the life of the patient is endangered by some alarming symptom.—Thus, in serious hemorrhages occurring during labour, after the rupture of the membranes, and where the placenta is not situated over the os uteri, the ergot is especially indicated.7 It has also been employed to accelerate delivery in puerperal convulsions. Five successful cases of its use are recorded by Bayle,8 on the authority of Waterhouse, Mitchell, Roche, Brinkle, and Godquin. But the narcotic operation of ergot presents a serious objection to its use in cerebral affections.

3. To provoke the expulsion of the placenta when its retention depends on a want of contraction of the uterus.—In such cases, ergot has often proved of great advantage.9 When the hemorrhage is excessive, the ergot must not be regarded as a substitute for manual extraction, since, during the time required for its operation, the patient may die from loss of blood.10 In retention of the placenta from spasmodic or irregular contraction of the uterus, as well as from morbid adhesion, ergot is improper or useless.11

4. To provoke the expulsion of sanguineous clots, hydatids, and polypi from the

---

8. Bibl. Thér. iii. 443 and 548.
9. Dr. Blundell, Lancet, 1827-28, vol. ii. 259; Bayle (Bibl. Thér. vol. iii. 541) has recorded nine cases from Balarudini, Bordoi, Davizia, Duchâneau, and Morgan; and many others will be found in the medical journals.
uterus.—Coagula of blood collected within the womb after delivery may sometimes require the use of ergot to excite the uterus to expel them, as in the case mentioned by Mackenzie.1 Ergot is also valuable in promoting the expulsion of those remarkable formations called uterine hydatids,2 and which are distinguished from the acephalocyats of other parts of the body by their not possessing an independent life, so that when separated from their pedicles they die.3 A successful case of the use of ergot in this affection has been published by Dr. Macgill.4 In uterine polypus, ergot has been exhibited with the view of hastening the descent of the tumour from the uterus into the vagina, so as to render it readily accessible for mechanical extirpation;5 for it is well known that, until this is effected, the patient is continually subject to hemorrhage, which in some cases proves fatal. In some instances, ergot has caused the expulsion of a polypus.6

5. To restrain uterine hemorrhage, whether puerperal or non-puerperal.—Ergot checks hemorrhage from the womb, principally, if not solely, by exciting contraction of the muscular fibres of this viscus, by which its blood-vessels are compressed and emptied, and their orifices closed. The experience of physicians and surgeons in all parts of the civilized world has fully and incontestably established the efficacy of ergot as a remedy for uterine hemorrhage.7 Maisonneuve and Trousseau8 have shown that the beneficial influence of ergot is exerted equally in the unimpregnated as in the impregnated state; proving, therefore, that the contrary statement of Prescott and Villeneuve is incorrect. Even in a case of cancer of the uterus, they have found it check the sanguineous discharge. In females subject to profuse uterine hemorrhages after delivery, ergot may be administered as a preventive, just before the birth of the child.9 Even in placenta presentations, a dose or two of ergot may be administered previously to the delivery being undertaken.10 To restrain excessive discharge of the lochia or catamenia, this remedy is sometimes most beneficial.

6. To provoke abortion, and to promote it when this process has commenced and is accompanied with hemorrhage.—Under certain circumstances, the practitioner finds it expedient to produce abortion: as in serious hemorrhage during pregnancy, and in deformed pelves which do not admit the passage of a full-grown fetus. In such cases, the ergot may be employed with great advantage.11 When abortion has already commenced, ergot may be employed to quicken the process and check hemorrhage.

7. In leucorrhoea and gonorrhoea.—Ergot was first given in leucorrhoea by Dr. M. Hall;12 and was subsequently employed by Dr. Spajrani13 with success; and in eight cases by Dr. Bazzoni,14 seven of these were cured by it. Dr. Negri15 published seven successful cases of its use. Its efficacy has been confirmed by many other practitioners. Dr. Negri also used it with apparent benefit in gonorrhoea, in both the male and female. He concludes that “secale cornutum has a peculiar action on the mucous membranes; but, if exhibited when there is a state of acute inflammation, their morbid secretions may be considerably increased; on the contrary, when a more chronic form of inflammation does exist, the secale cornutum may have a beneficial influence in arresting their preternatural discharge.”16

8. In hemorrhages generally.—The power possessed by ergot of exciting uterine contractions, readily explains the efficacy of this agent in restraining sanguineous discharges from the womb; but it has also been used to check hemorrhage from other organs. In these cases it can only act as a sedative to the circulation, in a

13 Lancet, Feb. 5th, 1831.
15 Neul, Researches, p. 88.
similar way to foxglove. A considerable number of cases have been published in proof of its power of checking hemorrhage from other organs (as the nose, gums, chest, stomach, and rectum). But, having found it unsuccessful in my own practice, seeing that in the hands of others it has also failed, and knowing how difficult it is to ascertain the influence of remedies on hemorrhages, I think further evidence is required to prove the anti-hemorrhagic powers of ergot.

9. In amenorrhœa.—Some few cases have been published tending to show that ergot possesses emmenagogue properties. It appears to me to be more calculated to cause than to relieve amenorrhœa.

10. In other diseases.—Ergot has been employed in various other diseases with apparent success; viz., intermittent fever, paraplegia, &c.

ADMINISTRATION.—Ergot is usually given in the form either of powder or infusion. The decoction, less frequently the tincture, and still more rarely the extract, are also used. Latterly, the ethereal oily extract and oil have been used.

1. PULVIS ERGOTÆ; Pulvis Secalis Cornuti; Powdered Ergot.—This powder is only to be prepared when required for use. The dose of it, for a woman in labour, is twenty grains, to be repeated at intervals of half an hour for three times; for other occasions (as leucorrhœa, hemorrhages, &c.), five to ten or fifteen grains three times a day: its use should not be continued for any great length of time. It may be taken mixed with powdered sugar. It has had the various names of pulvis parturien (more correctly parturificiens), pulvis ad partum, pulvis partem accelerans, obstetrical powder, &c.

2. INFUSUM ERGOTÆ, D.; Infusum Secalis Cornuti; Infusion of Ergot.—Ergot, in coarse powder, ½ j; Boiling Water ½ jix. Infuse for one hour, in a covered vessel, and strain. The product should measure about eight ounces. The dose for a woman in labour is ½ jij, to be repeated at intervals of half an hour or an hour. Sugar, aromatics (as nutmeg or cinnamon), or a little wine or brandy, may be added to flavour it.

3. TINCTURA ERGOTÆ, D.; Tinctura Secalis Cornuti; Tincture of Ergot.—(Ergot, in coarse powder, ⅜ j; Proof Spirit Oij. Macerate for fourteen days, strain, express, and filter, D.).—Five fluidrachms of this tincture contain one drachm of ergot. Dose ½ j to ½ jij.

Various other formulæ have been published, some made with rectified, others with proof, spirit. In most of them the proportion of ergot is smaller than in the Dublin formula. One formula orders of Ergot, bruised, f r j; Boiling Water f r j. Infuse for twenty-four hours, and add Rectified Spirit f r jiss. Digest for ten days. Half a drachm of this tincture is said to be equivalent to ten grains of the powder. One or two spoonfuls of a tincture of ergot (prepared by digesting ½ ss of ergot in Ⅲ iv of rectified spirit), mixed with water, has been recommended as an injection into the uterus in difficult labour. It is to be introduced between the head of the child and the neck of the uterus.

4. TINCTURA ERGOTÆ ÆTHEREA, L.; Tinctura Secalis Cornuti Ætheræa; Æthereal Tincture of Ergot.—(Ergot, bruised, ⅚ y; Ether Oij. Macerate for seven days; then express and strain, L.).—Half a fluidounce of this tincture contains a drachm and a half of ergot. The dose is a teaspoonful. The objection to this preparation is that it is not miscible with water.

The Æthereal solution of ergot, used by Dr. Lever to promote uterine contraction, is essentially a solution of the oil of ergot. It was prepared by digesting Ⅲ iv of

powdered ergot in f3iv of ether during seven days. The tincture was submitted to spontaneous evaporation, and the residue dissolved in f3ij of ether. The dose of this solution is from $\pi_{xv}$ to $\pi_{xxx}$ on a lump of sugar.

[5. VINUM ERGOTÆ, U. S.; Wine of Ergot.—Take of Ergot, bruised, two ounces; White Wine a pint. Macerate for fourteen days, with occasional agitation; then express and filter through paper. This preparation is used as a substitute for the tincture. Dose, f3j, or f3ij.]

6. OLEUM ERGOTÆ; Oil of Ergot.—The liquid sold in the shops under the name of pure oil of ergot is obtained by submitting the ethereal tincture of ergot to evaporation by a very gentle heat. Its colour is reddish brown. Mr. Wright\(^1\) states that this depends on the age of the ergot, and that when obtained from recent specimens it is not unfrequently entirely free from colour. Its taste is oily and slightly acid. It is lighter than water, and is soluble in alcohol and in solutions of the caustic alkalies. It is probably a mixture of several proximate principles. I made a guinea-pig swallow a fluidrachm of it: the only obvious effect was copious and frequent diuresis. Two fluidrachms diffused through water and injected into the jugular vein of a dog, caused trembling of the muscles, paralysis of the hind, and great weakness of the fore legs, which lasted for more than two days. The respiration and action of the heart were exceedingly rapid. The saliva streamed copiously from the mouth. The pupil was strongly dilated before the experiment, and no obvious change in it was induced by the oil. Mr. Wright found the oil very energetic. A drachm, he states, injected into the jugular vein caused dilatation of the pupil, feeble, slow, and intermittent action of the heart, deep and interrupted respiration, general paralysis, insensibility to punctures, and death in two hours and forty minutes.

According to evidence adduced by Mr. Wright, the oil possesses the same influence over the uterus as that of the crude drug; that is, it occasions powerful uterine contractions. To produce this effect, it should be given in doses of from 20 to 50 drops in any convenient vehicle, as cold water, warm tea, or weak spirit and water.

7. EXTRACTUM ERGOTÆ; Extractum Secalis Cornuti; Bonjean's Ergotine.—This is prepared by exhausting ergot of rye by means of water, and evaporating the liquor to the consistence of syrup. To this extract is to be added a considerable excess of alcohol, by which all the gummy matters and salts insoluble in alcohol are precipitated. The supernatant liquid is to be decanted and reduced in a water bath to the consistence of a soft extract. From 100 parts of ergot, from 14 to 16 parts of extract, called, by Bonjean, ergotine, are obtained. This extract is soft, reddish-brown, and homogeneous; has an odour of roast meat, and a slightly piquant bitter taste. It may be employed medicinally in substance, made into pills, or dissolved in water. The dose of it is from five to ten grains. The aqueous solution of it is red, limpid, and transparent.

ANTIDOTE.—The proper treatment to be adopted in a case of poisoning by an overdose of ergot has not been accurately determined. The first object would be, of course, to evacuate the poison from the alimentary canal by the use of emetics or purgatives. As chlorine decomposes ergotin, Phæbus recommends the employment of chlorine water. In the absence of this, nitro-hydrochloric acid (properly diluted) might be exhibited. The subsequent treatment should be conducted on general principles.

40. SACCHARUM OFFICINARUM, Linn.—THE SUGAR CANE.

Sect. Syst. Triantria, Digynia.

(Saccharum; caulis succus preparatus purificatus crystallinum. Sacchari Fæx; succus preparatus impurus, L.—Saccharum commune; Sacchari Fæx; Saccharum purum, E.—Saccharum purificatum; Refined Sugar; White Sugar.—Thehices; Treacle; Molasses; or the concentrated uncrystallized juice, D.)

History.—The manufacture of sugar is said by Humboldt to be of the highest antiquity in China. Cane-sugar was known to the ancient Greeks and Romans, and was considered by them to be a kind of honey. Possibly, Herodotus refers to it when he says that the Zygantes make honey in addition to that which they get from bees. Theophrastus calls it mel in arundinibus; Dioscorides terms it sakkapovi; Pliny saccharum. Humboldt adopts too hastily, I think, the opinion of Salmasius, that the latter writers meant the siliceous product of the Bamboo, viz., Tabasheer; for, in the first place, as they arrange it with honey, it was probably sweet, which tabasheer is not; secondly, the Sanscrit name for sugar is Sarkura, thirdly, a passage in Lucan seems distinctly to refer to the sugar-cane: "Quique bibunt tenera dulces ab arundine succos." Surely no one will pretend that the bamboo is a "tenera arundo." 11

Botany. Gen. Char.—Spikelets all fertile, in pairs; the one sessile, the other stalked; articulated at the base, two-flowered; the lower floret neuter, with one palea; the upper hermaphrodite, with two paleae. Glumes two, membranous. Paleæ transparent, awnless; those of the hermaphrodite flower minute, unequal. Stamens three. Ovary smooth. Styles two, long; stigmas feathered, with simple toothed hairy hairs. Scales two, obscurely two or three-lobed at the point, distinct. Caryopsis smooth (?), loose (?). (Kunth.)

Sp. Char.—Panicle effuse. Flowers triandrous. Glumes obscurely one-nerved, with very long hairs on the back (Kunth).

The stem is solid, from six to twelve feet high. Leaves flat. Panicle terminal, from one to three feet long, of gray colour, from the long soft hair that surrounds the flower. Paleæ rose-coloured.

Kunth admits four varieties:

a. commune, the common yellow cane, called by the Bengalees Poor; and, by the West Indians, the Creole Cane or Native Cane, from its having been the one originally introduced into the New World.

b. purpureum, the purple cane, called by the Bengalees Kajooli; and which is said to yield juice one-eighth richer than the yellow cane.

c. giganteum, the giant cane, a large light-coloured cane, called by the Bengalees Kulboo. It grows in a low swampy soil, where the other two will not succeed. Its juice is weaker than that of the yellow cane, but the plant grows to a much larger size; and it is, therefore, much cultivated in India.

b. tahitense, the Tahita cane, commonly called the Otaheite cane.

Hab.—It is cultivated in both Indies. Its native country is uncertain.

Two other species of Saccharum are cultivated for the sugar they produce:—

S. violaceum, Tussac, Antill. i. 100.—Kunth, Agrostogr. i. 474; Violet Sugar-cane. (By some authors considered to be identical with Tahiti sugar cane above mentioned.)—Cultivated in both Indies.

S. sinense, Roxb., Fl. Ind.; China Sugar-cane.—Cultivated in China, where sugar is made from it.

THE SUGAR-CANÉ:—Composition; Properties.

145

Composition of the Sugar-cane.—Avequin ¹ analyzed the Tahiti and ribbon varieties of the fresh sugar-cane of Louisiana, and Dupuy ² analyzed the fresh sugar-cane at Guadaloupe. Peligot, ³ by combining the composition of cane-juice with that of the dried canes sent him from Martinique, has also deduced the composition of the fresh cane. More recently, Casaseca ⁴ analyzed the sugar-cane of Cuba.

The dried sugar-cane was analyzed by O. Hervey. ⁶ The composition of sugar-cane ash is an important consideration for the sugar-planter, as it enables him to deduce the most appropriate manure for promoting the growth of the cane. ⁷

The sugar-cane, especially the violet variety, is coated by a glaucous powder of a peculiar kind of wax, which has been called cerosine or sugar-cane wax. ⁷ This is fusible at 150° F., and dissolves in boiling alcohol: the alcoholic solution, even when it contains but a small quantity of cerosine, gelatinizes or solidifies on cooling like an alcoholic solution of soap. The composition of this wax is C₃H₆O₃ ² (Dumas).

Extraction of Cane-Juice.—Cane-juice is generally extracted from the stems by means of the sugar mill. The canes, when ripe, are cut close to the ground, stripped of their leaves, and carried in bundles to the mill-house, where they are twice subjected to pressure between iron rollers, placed either vertically or horizontally. The residue of the canes which have been thus crushed and deprived of their juice is called meggass.

Other methods of extracting the cane-juice have been suggested. The hydraulic press has been introduced into Jamaica and St. Vincent’s. By Michiel’s patent it is proposed to macerate thin slices of the cane in a mixture of lime and water, so as to conglutinate the albuminous matters but to extract the sugar. It has also been proposed to extract the sugar in Europe from the canes imported in the dried state. ⁸

Properties of Cane-Juice.—Cane-juice is pale yellowish-gray, and has an agreeable sweet taste and a faint fragrant odour. As it flows from the mill it is frothy, and, owing to the suspension in it of finely-divided matter, is turbid or opalescent. Its sp. gr. ranges from 1.067 to 1.106: Mr. Fournes ⁹ found it to be from 1.070 to 1.090. By boiling, its turbidity is commonly a little increased, and sometimes a few small flocks are separated from it. Both nitric acid and corrosive sublimate occasion, after a time, a very slight precipitate. A large addition of alcohol throws down flocks resembling gum or dextrine. A few drops of sulphate of copper, and an excess of caustic potash, occasion, on heating, a very abundant red precipitate of suboxide of copper, indicative of the presence of glucose or grape-sugar.

According to Mr. Fournes, the juice contains the following substances: Cane-sugar in great quantity, a notable amount of glucose or grape-sugar, gum or dextrine, phosphates of lime and magnesia, some other salt of lime and magnesia, sulphates and chlorides, potash and soda; and, lastly, a peculiar azotized matter belonging to the albuminous family, forming an insoluble compound with lime.

not coagulable by heat or acids, and readily putrefiable. Of ordinary vegetable albumen there are but indistinct traces, and of casein or legumine none. Avequin found a portion of cerosine or sugar-cane wax in cane-juice. It is detached from the canes in the mill.

Cane-juice has been analyzed by Proust,\(^1\) by Avequin,\(^2\) by Peligot,\(^3\) by Plagne,\(^4\) and by Casaseca.\(^5\) The following are their more important results:—

Cane-juice | 100.00 | 100.00 | 99.94\(\%\) | 100.00

It appears, therefore, from these analyses, that cane-juice contains about 20 per cent. of saccharine matter. Or, assuming that the juice has an average sp. gr. of 1.073, the quantity will be 18 per cent. Moreover, according to both Peligot and Casaseca, the whole of the saccharine matter is crystallizable, or true cane-sugar; the uncrystallizable sugar, or molasses, which is obtained by evaporation from the juice, being the product of alterations effected in the crystallizable sugar by the operation: but Mr. Fownes observed that this statement must be received with some reservation.

Of late years, concentrated West Indian cane-juice has been imported. It contains nearly half its weight of granular sugar, besides a variable amount of molasses.

**Clarification of Cane-Juice.**—The clarification or defecation of cane-juice is effected, usually in large copper vessels of the capacity of 300 or 400 gallons, by the combined use of heat and lime: the latter is technically called "the temper." The heat serves to coagulate any vegetable albumen which may be present. The lime neutralizes the free acid and combines with the peculiar albuminous or proteine body mentioned by Mr. Fownes, and forms a coagulum, the separation of which is promoted by the heat. Part of it rises to the top as a scum, and the remainder subsides as a thick muddy deposit.

Various other substances have been tried as a substitute for lime with more or less success. Diacetate of lead has been employed for this purpose, but its use has been discontinued on account of a great number of persons having suffered the ill effects of this metal from partaking of sugar prepared with it.

**Concentration of the Cane-Juice.**—The clarified juice should be filtered prior to evaporation. This, however, is not usually practised. It is generally drawn off from the clarifier into a copper boiler, where it is evaporated and skimmed. It is then passed successively through a series of boilers, the last of which is called the teache. When it has acquired a proper tenacity and granular aspect, it is emptied or "skipped" first into a copper cooler and afterwards into a wooden vessel, where it is allowed to crystallize or grain. The concrete sugar is then placed in casks (usually sugar hogsheads) perforated with holes in the bottom, each of which is partially closed by the stalk of a plantain leaf. Here the sugar is allowed to drain for three or four weeks. It is then packed in hogsheads and sent to this country under the name of muscovado or raw sugar.

The drainings, or uncrystallized portion of sugar, constitute molasses. This is received in an open cistern beneath.

The feculencies separated in the clarifying vessel, and the skimmings of the evaporating coppers, are employed in the manufacture of rum.

**Properties of Raw Sugar.**—Raw sugar is a mixture of crystallizable and uncrystallizable sugar, contaminated by various organic and mineral substances. Its mineral constituents are, according to Avequin, silica, phosphate and subphos-

6. See Dr. Evans’s Sugar-Planter’s Manual.
The Sugar-Cane:—Sugar Refining.

The raw sugar of the shops reddens litmus, and is not completely soluble in alcohol. Its aqueous solution yields precipitates with the diacetate of lead, oxalic acid, and caustic ammonia; and is frequently darkened by the addition of the sesquichloride of iron. By keeping, strong raw sugar becomes weak—that is, soft, clammy, and gummy. This change the late Mr. Daniell† ascribed to the action of the lime.

Sugar Refining.—The following is a sketch of the process as usually practised in London: Raw sugar is dissolved in water by the aid of steam (this process is called giving the sugar a blow-up). The liquid is then heated with bullock's blood (technically called spice), and filtered through canvas bags (called Schröder's bags). The clear liquor is allowed to percolate slowly through a bed of coarse-grained animal charcoal placed on a woollen cloth, supported on a false bottom of basket-work, and contained in a large wooden vessel. The depth of the bed of charcoal varies in different refining-houses. I have seen it three feet deep; but I am told that some refiners employ a bed twenty feet in depth. The filtered liquor, which is nearly colourless, is conveyed to a copper vessel (Howard's vacuum-pan), where it is boiled by the aid of steam, under diminished atmospheric pressure, at a temperature of about 170° F.

Fig. 215.

View of two Vacuum Pans and their subsidiary Apparatus.

a a. Charging measures, supplied by pipes, which descend from c c, the liquor cisterns. d d, are the vacuum spheroidal pans, the lower half of each being supplied with a jacket, as a case for the steam. At the sides of the neck of each pan are a barometer and thermometer. Below the neck, and just above the horizontal line b b, is the handle of the proof-stick, which appears like a stop-cock. When the syrup is sufficiently concentrated, it is discharged into the heater, e e.

The consistence of the liquid is examined from time to time by taking out a sample by the proof-stick, which is so constructed as not to admit air.

When the requisite degree of concentration has been attained, a valve is opened in the bottom of the vacuum pan, and the syrup allowed to escape into a copper vessel (heater), enveloped by a jacket, so as to enable it to be heated by steam. The syrup is then transferred to conical moulds (made of earthenware or iron), whose orifices are closed by a paper plug, and the next morning, when solidified, these moulds are carried to the curing-floor, when the stoppers are withdrawn and

† Quarterly Journal of Science, vi. 35.
‡ At one time hydrate of alumina, under the name of finings, was used in addition to blood.
the moulds placed in pots, in order to allow the green syrups to drain off: these are made into an inferior sort of refined sugar (brown lumps). The loaves are then either clayed or sugared, generally the latter.

Claying (which is now almost entirely out of use) consists in pouring clay and water on the base of the sugar loaf: the water slowly percolating through the sugar, a portion of which it dissolves, carries with it the colouring matter and other impurities. Sugaring is effected by substituting a saturated solution of pure sugar (called liquor) for the clay and water; it washes out the colouring matter, but does not dissolve the pure sugar. The loaves are afterwards dried in a stove, and put in blue paper for sale.

The following may be regarded as an approximation to the produce of 112 lbs. of raw sugar by the above process:

| Refined sugar | 70 lbs. |
| Bastard | 17 |
| Treacle | 16 (12 lbs. solid matter.) |
| Water | 4 |
| Raw sugar | 112 |

The animal charcoal used in sugar refining is changed every week, and of course is a more powerful decolorizer when fresh than when it has been used several times. It follows, therefore, that the quality of the refined sugar obtained varies with the day of the week—that is, with the age of the charcoal. At the commencement of the week, when the charcoal is fresh, the finest white loaves of sugar are made; about the middle of the week titlers and lumps are obtained; and, at the end of the week, bastards.

In the process of sugar refining, various salts have been proposed to be used as defecators; such as the trisacetate of lead, acetate of lead, bisulphite of lime, sulphate of tin, &c. The salts of lead are probably the most effective agents, but, on account of their poisonous properties, are dangerous to the public health.

Properties.—Common or cane-sugar is the sweetest of all kinds of sugar. When pure, it is white and odourless. It is very soluble in water, both hot and cold (see Syrupus, vol. i. p. 153); is soluble in rectified spirit, but not in ether. Its watery solution, aided by heat, decomposes some of the metallic salts (as those of copper, mercury, gold, and silver); but several of them (as the diacetate of copper and nitrate of silver) require nearly a boiling temperature to change them. A dilute watery solution of common sugar, with a little yeast, undergoes the vinous fermentation. Sugar promotes the solubility of lime in water, and forms both a soluble and an insoluble compound with oxide of lead.

Cane-sugar is capable of existing either in the crystallized or amorphous state. In this respect it resembles sulphur (see vol. i. p. 355).

1. Crystalized Cane-sugar.—To this division are referred sugar-candy and the ordinary loaf and lump sugar of the shops. By the slow cooling of a saturated aqueous solution of sugar, we obtain the large and fine crystals which constitute the commercial sugar-candy (saccharum candum), and of which three kinds are kept in the shops; namely, white candy, prepared from pure sugar; brown candy, prepared from brown sugar; and pink or rose candy, prepared from sugar artificially coloured (probably by cochineal).

The crystals of sugar are doubly oblique prisms, and, therefore, have two axes of double refraction (see vol. i. p. 187). Their sp. gr. is 1.6065.

Common crystalized sugar is permanent in the air and phosphorescent in the

---

1 "Claying sugar, as they report here, was first found out in Brazil: a hen, having her feet dirty, going over a pot of sugar by accident, it was found under her tread to be whiter than elsewhere."—Slonne's Jamaica, vol. i. p. 61.

2 For further details, consult a paper by Messrs. Guyenne and Young, Brit. Ann. of Med. June 23 and July 14, 1837; also, Dr. Ure's Dict. of Arts, art. Sugar.

4 Siever and Scoffern, Pharmaceutical Journal, vol. ix. and x.

7 Sugar-candy makes an interesting polariscope object. It is usually cut so as to show one only of its two systems of rings.
dark when struck or rubbed. When heated, it melts and soon becomes coloured. By this process, its tendency to crystallize is diminished or destroyed.

The commercial varieties of common crystallized cane-sugar are of two kinds—white or brown. The first is refined sugar.

1. Purified or Refined Sugar (Saccharum, L.; Saccharum purpurum, E.; Succus concretus purificatus, D.; Saccharum purpureum) is met with in the shops in conical loaves (loaf sugar) or truncated cones, called lumps (lump sugar), of various sizes and degrees of purity. Small lumps are called tilets. The finest refined sugar (Saccharum albissimum) is perfectly white, and is termed double refined; the inferior kind (Saccharum album) has a slightly yellowish tint, and is called single refined. Both varieties are compact, porous, friable, and made up of small crystalline grains.

2. Brown Sugar (Saccharum commune, E.; Saccharum fuscosum; Succus concretus non purificatus, D.) occurs in commerce in the form of a coarse powder composed of shining crystalline grains. It is more or less damp and sticky, and has a peculiar smell and a very sweet taste. Its colour is brownish-yellow, but varying considerably in intensity. Muscovado, or raw sugar, has the deepest colour, and is intermixed with lumps. Bastard is a finer kind, prepared from molasses and the green syrups. The Demerara crystal sugar is the finest: its colour is pale yellow, and its crystals are larger and more brilliant than the preceding varieties.

2. Amorphous Cane-sugar. When syrup or a strong solution of crystallized cane-sugar is rapidly boiled down, and then poured out on a marble or metallic plate, it congeals in an amorphous, vitreous, more or less coloured mass, usually called boiled sugar, of which barley-sugar (Saccharum hordeatum), acidulated drops, and hard-bake, are familiar examples. During the preparation of barley-sugar and acidulated drops, the confectioners usually add a small quantity of cream of tartar to the melted sugar, in order to destroy its tendency to crystallize. Vinegar and tartaric acid are mentioned by some writers as being used for this purpose. If when the melted sugar has partially solidified, but while it is yet soft, it be hung on a hook and rapidly and repeatedly drawn out, it becomes opaque and white. This pulled sugar was formerly termed sugar penides (Saccharum penides).

When crystallized cane-sugar is subjected to a temperature of about 350° F., it melts; and, at a higher temperature, begins to give off water and to suffer decomposition. If the heat be gradually augmented, it becomes brown, evolves a remarkable odour, loses its sweet taste and acquires a bitter one. In this condition it is called caramel (from καραμέλη, I burn, and μέλι, honey), or burnt sugar (Saccharum tautom). It enjoys acid properties, and is composed, according to Peligot, of C12H20O11.

Molasses and Treacle. These are viscid, dark brown, dense liquids, composed of amorphous or uncrystallizable sugar, crystallizable sugar, gum, extractive, various salts, and water. They are frequently confounded, but in trade are considered distinct.

1. Molasses (more correctly Melasses, from mel, honey, because it is soft and sweet like honey) is the drainings from raw or muscovado sugar. West India molasses is occasionally imported for refining. It yields brown sugar, or bastard, and treacle.

2. Treacle (Theriaca, D.; Faz Sacchari, L. E.) is the viscid, dark brown, uncrystallizable syrup which drains from refined sugar in the sugar moulds. It is thicker than West Indian molasses, and has a somewhat different flavour. Its sp. gr. is generally 1.4; and it contains, according to Dr. Ure, on an average, 75 per cent. of solid matter. Payen says that it may be regarded as a saturated solution of crystallizable sugar, of which it contains from 40 to 50 per cent. of its weight. It is employed in the manufacture of gingerbread, and, by poor people, as a substitute for sugar. It is also sometimes used to yield, by fermentation, an alcoholic liquor—either to be drank as a kind of beer, or to yield, by distillation, spirit. It is sold under the names of "melasse de la Cochinchine" and "prepared melasse," to be taken with lentilmeal (sold as eravenda or revalenta arabica), as a remedy for habitual constipation.

Chemical Characteristics. As a species of sugar, cane-sugar is known by its susceptibility of undergoing the vinous fermentation; that is, of suffering a peculiar decomposition into alcohol and carboonic acid. For this purpose it is dissolved

---

2 Mannonis, glycyrhizae, glicerina, and some other sweet substances, which were formerly called sugars, are, by modern chemists, excluded from the list of sugars, properly so called, because they are incapable of undergoing the vinous fermentation.
in water, and to the solution a small portion of yeast (dry yeast is to be preferred) is added, and the mixture exposed to a temperature of about 70° F. Effervescence soon takes place, carbonic acid is evolved, and a vinous or alcoholic liquor is produced. In this process the cane-sugar combines with water, and becomes grape-sugar, \( \text{C}_6\text{H}_12\text{O}_6\), which, by fermentation, is resolved into four atoms of carbonic acid, \( 4\text{CO}_2 \), and two atoms of alcohol, \( 2\text{C}_2\text{H}_5\text{O}_2 \).

The quantitative determination of sugar is effected by ascertaining the amount of carbonic acid evolved during fermentation. 171 grains of sugar-candy furnish 88 grains, or about 186.4 cubic inches of carbonic acid gas. At mean temperature and pressure, 100 cubic inches, or 47.2 grains, of carbonic acid gas are given out by 91.7 grains of sugar-candy. In round numbers, we may say that one cubic inch or half a grain of carbonic acid gas is equal to one grain of sugar-candy.

Cane-sugar is distinguished from other kinds of sugar by the following characters:—Its crystallizability in prismatic crystals, its very sweet taste, its ready solubility in water, its solution being charred and letting fall a brown or black powder when heated with a few drops of oil of vitriol, but being unchanged when treated in the same way with caustic potash—and by the difficulty with which it reduces the blue hydrated oxide of copper to the orange suboxide.

Grape-sugar reduces the hydrated oxide of copper to the suboxide with great facility. The test is applied thus: Add to the saccharine solution a small quantity of a solution of caustic potash, and then a few drops of a weak solution of sulphate of copper; taking care that the alkali is in excess. Then apply heat: if grape-sugar be present, an ochre-yellow or red precipitate of suboxide of copper is formed before ebullition takes place. Uncrystallizable sugar, as well as sugar of milk, also readily reduces the oxide; but this effect does not take place with crystallizable cane-sugar; or rather, a higher temperature or a longer action of the ingredients is required to produce the effect. This is called Trommer's test.

A solution of crystallizable cane-sugar is distinguished from solutions of some other kinds of saccharine matters by possessing the property of right-handed circular polarization.

If a ray of common light (Fig. 216, \( a \)) be polarized by reflection at an angle of 56°.45 from the surface of glass\(^8\) (\( b \)), the plane polarized ray (\( c \)), which is thus obtained, transmitted through a pure solution of crystallizable cane-sugar (\( d \)), and the emergent ray (\( e \)) ana-

---

1. Full directions for the quantitative determination of sugar by fermentation are given by Dr. Miller, in the article Organic Analysis of the Cyclopaedia of Anatomy and Physiology, vol. iii. p. 729.
2. The plane polarization of the ray may be effected by a Nichol's prism instead of a glass-mirror. The use of a silvered glass-mirror is objectionable, on account of its producing elliptical polarization.
(x) by extraordinary refraction. The colours of the images are complementary; that is, when one image is red, yellow, or blue—the other is green, violet, or orange. By rotating the analyzer (the rhomb of calcareous spar), the colours change: if the rotation be right-handed (that is, as we turn a screw or corkscrew to make it enter), the sequence of the colours is red, orange, yellow, green, blue, indigo, and violet.

**Sequence of Colours for a Solution of Crystallizable Cane-sugar, as obtained by the Right-handed Rotation of the Analyzer.**

**Adulteration; Purity.**—The purity of genuine sugar is readily judged of by its physical or sensible qualities. The impurities may also be detected by chemical means, but it is rarely necessary to resort to these. A solution of pure sugar is colourless, and yields no precipitate with oxalic acid, diacetate of lead, or caustic ammonia. Pure sugar is completely soluble in rectified spirit.

Brown sugar of commerce contains crystallizable and uncrystallizable sugar, woody tissue of the sugar-cane, vegetable albumen, siliceous particles, sporules and filaments of fungi; and, in most samples, a peculiar species of mite (Acarrus), which has been called the sugar mite² (acarrus sacchari). In most cases the animal is dead, but frequently it is met with in the living state. Starch or flour is also said to be found in brown sugar.

Various adulterations have been practised on sugar. The most important of these is the intermixture of starch sugar. A few years ago I inspected an extensive manufactory of sugar from potato-starch at Stratford, in Essex: the sugar obtained was sold for the adulteration of brown sugar, and the molasses produced was consumed in an oxalic acid manufactory. Brown cane-sugar adulterated with starch sugar is less sweet, less readily soluble in water, and less crystalline and sparkling than pure brown cane-sugar. Moreover, potato-sugar always contains sulphate of lime, the detection of which (see the tests for sulphuric acid and lime, pp. 368 and 562) in a suspected sample of sugar is, therefore, of some value. It has been proposed to detect the presence of potato-sugar by Trommer's test (see ante, p. 150) and by caustic potash. But though Trommer's test readily detects starch-sugar in a solution of white cane-sugar, the detection is not so easily effected by it in a solution of brown cane-sugar, because the uncrystallizable cane-sugar, or treacle, which

¹ The nature of the present work does not admit of a further elucidation of circular polarization, which I have here introduced as an aid in the qualitative determination of a saccharine solution. Biot has applied it to the quantitative determination of sugar. To his various papers contained in the Mémoires de l'Académie des Sciences, and especially to his Instructions Pratiques sur l'Obscrvation et la Mesure des Propriétés Optiques appelées rotatoires, Paris, 1845, the reader is referred for further information. See also, the article Saccharimétrie Optique, in Pelouze and Fremy's Cours de Chimie Générale, t. iii. p. 337, 1850.—A popular sketch of the subject will be found in my Lectures on Polarized Light, published by Messrs. Longman and Co.—A very admirable report on this and other methods of effecting the qualitative and quantitative analysis of sugars, syrups, and molasses, by Professor R. S. McCulloch, is contained in a Letter from the Secretary of the [United States] Treasury to the United States Senate, read Feb. 21, 1835.

is present readily reduces the blue hydrate of copper to the orange suboxide—acting thus like starch-sugar. Chevallier\(^1\) proposes to detect starch-sugar in cane-sugar by means of caustic potash: Boil the suspected sugar in a lea of caustic potash: if no starch-sugar be present, the liquor remains colourless; but, on the contrary, it becomes brown if starch-sugar be present. But this test, like the last one, is better adapted for detecting starch-sugar in white cane-sugar than in the ordinary brown cane-sugar of the shops.\(^2\)

Farinaceous substances and dextrine may be detected by boiling the suspected sugar in water and testing the decoction, when cold, with iodine, which causes a blue colour with starch and a purplish colour with dextrine.

Gum is distinguished from sugar by its insolubility in rectified spirit.

Various other substances have, it is said, been used for the adulteration of sugar; as finely-powdered marble, chalk or whiting, sand, bone-dust, and common salt. With the exception of salt, all the substances here mentioned are insoluble in water, and by this character, therefore, may be readily separated from sugar. Common salt may be detected in a solution of the suspected sugar by the ordinary tests for that substance (see vol. i. p. 537).

**Physiological Effects.**—Sugar, considered as an article of food, is an alimentary principle which belongs to the class of "elements of respiration," (see vol. i. p. 117.) It contributes to the formation of fat and of lactic acid, and by its oxidation furnishes heat. It has recently been detected in the tissue of the liver, but in no other organ.\(^3\)

It disagrees with some dyspeptics, and is reputed to have a tendency to cause flatulency and preternatural acidity (by the formation of lactic acid?) of the primae vicie.

Treacle, and therefore raw sugar, check the tendency to constipation.

**Uses.**—Sugar is used dietetically, medicoinally, and pharmaceutically. Medicinally, it is but little employed. In the form of lozenges, sugar-candy, &c., it is slowly dissolved in the mouth to allay tickling cough. As a chemical antidote, it has been recommended in poisoning by the salts of copper, mercury, silver, gold, and lead.\(^4\) But any advantage procured by its use in these cases is referable to its demulcent and emollient properties, and not to its chemical influence. The same remark may be made with respect to the benefit said to have been obtained by the use of the juice of the sugar-cane in poisoning by arsenious acid.\(^5\) Powdered white sugar is sometimes sprinkled over ulcers, to remove spongy granulations, denominated proud flesh. The same remedy has also been employed for the removal of specks on the cornea.

In pharmacy, the uses of sugar are much more extensive. It serves to preserve, to give flavour, bulk, form, colour, cohesiveness, and consistency; to subdivide and to suspend oily substances in aqueous liquids. To fulfil one or more of these objects, it is a constituent of syrups, elcosacharar, conserves, electuraries, confectons, lozenges, some pills and powders, &c. For making pills, treacle serves to give cohesiveness, to preserve the pill-mass soft, prevent mouldiness, and in some cases to check chemical changes. As an antiseptic, it is used for the preservation of various medicinal organic substances. It acts in at least two ways—by excluding air and by absorbing moisture (see vol. i. p. 205); and perhaps, also, in some other way—as when it promotes the solidification of pectine. Sugar is also useful in preserving some inorganic compounds: thus it checks, though it does not absolutely prevent, the higher oxidation of some of the protosalts of iron; hence its

---

\(^2\) On a trial for the recovery of excise duties on potato-sugar, it was stated that this sugar possessed only three-fifths of the sweetening properties of genuine cane-sugar, and that it was mixed with whiting, bone-dust, &c. previous to its being offered for sale. (Pharm. Journ. vol. i. p. 603, 1842.)

\(^3\) Comptes rendus, xxvii. p. 614; Chemical Gazette, March 1, 1849.

\(^4\) Vogel and Buchner, in Schottenger's Journal. xiii. 102; xiv. 221.

\(^5\) Chisholm, Quarterly Journal of Science, x. 193.
use in the *ferri carbonas saccharatum* (see vol. i. p. 724), and *syrupus ferri iodidi* (see vol. i. p. 744).

It is employed in the manufacture of oxalic acid; and it is sometimes used in distilleries to yield, by fermentation, alcohol. The Edinburgh College directs it to be used in the rectification of sulphuric acid (see vol. i. p. 359).

As a test, it is sometimes used in the laboratory in conjunction with oil of vitriol, to detect the choleic acid of bile.

1. **SYRUPIS, L. [U. S.]: Syrupus simplex, E. D.; Syrup; Simple Syrup.**—(Sugar Biji [Bijv, D. (Bijius, U. S.)]; Water Oj [Oij, D. (Oj, U. S.)]). Dissolve the sugar in the water by a gentle heat.—By keeping for several months, syrup undergoes some molecular changes, by which its power of producing right-handed circular polarization is considerably diminished.

The proportion of water and sugar used by the London College is, by weight, water 1 part, sugar 1.9748 parts; by the Edinburgh College, water 1 part, sugar 2.1942 parts—or, very nearly, water 1 part, sugar 2 1/4 parts; and, by the Dublin College, water 1 part, sugar 2 parts.

In order to yield a clear and bright syrup, distilled water and well-refined sugar should be employed. Ordinary spring water becomes turbid by boiling, owing to the precipitation of carbonate of lime.

The sp. gr. of boiling syrup should be 1.264 (equal to 30° of Beaume’s aræometer). When it has cooled down to 60° F., its sp. gr. should be 1.32 (equal to 35° of Beaume’s aræometer). The Dublin College states the sp. gr. of simple syrup to be 1.330.

Syrup is used in medicine to give flavour, cohesiveness, and consistence.

2. **LIQUOR SACCHARI TOSTI; Caramel; Burnt Sugar.**—This is a useful, innocuous colouring agent. It is prepared by melting half a pound of brown sugar in an iron pot, and applying heat until the liquid acquires a deep brown colour; then adding a gallon of boiling water.

41. **Andropogon muricatus, Retz.—Vittie-Vayr, or Cuscus.**

*Sex. Syst. Triandria, Digynia.*

(Radix.)

*Virana, Asiat. Res. iv. 306; A. squarrosus, Linn., Suppl. 433; Phalaris zizanoides, Linn., Syst. Veg. v. 104; Anatherum muricatum, Bennv., Agrost. 128, t. xxii f. 10; Vetiveria odorata, Virey, Journ. de Pharm. xii. 499; Bena (Bengmele), Roxburgh, Fl. Ind. i. 265; Vittie-Vayr (Tamool), Ainalie, Mat. Indica, ii. 470; Waiswan (Tamool), Roxb. op. supra cit.—Coromandel, Bengal: very common on every part of the coast.—Its root, called *cucus*, or *khuz-khus* (*radix vetiveriae*), is imported from Bombay: it is long, fibrous, brownish or yellowish-white; has a fragrant aromatic colour, and a feeble bitterish, aromatic taste. Iodine colours it bluish-black. In 1809, Vanquelin analyzed it under the name of *schenanthis*. It was analyzed in 1828 by Henry, and in 1831 by Geiger; the latter found volatile oil, resin, bitter extractive, starch, traces of hydrochloric and calcareous salts and woody fibre. Capo submitted the root to distillation with water, and obtained two volatile oils: one limpid, amber-coloured, and lighter than water; another, in larger quantity, which was heavier than water, opake, and adhered to the bottom of the receiver. The dried roots, when slightly moistened, emit a pleasant kind of fragrance, and are employed in India for making vissoaries (large fans) and door- and window-screens (composed of a frame-work of bamboo covered by cuscus root). During the hot winds, the outsides of these screens are kept watered by natives, and the air that passes through is thereby rendered both cool and fragrant. Cuscus root is imported into England for perfumery purposes. It serves to make scented baskets, and is put into drawers to guard linen and woollen goods from the attacks of insects. This root has also been employed in medicine. It acts as a gentle

---

1 See some observations by Mr. Savory, on the preparation of syrup, in the *Pharmaceutical Journal*, vol. ii. p. 420, 1843.

2 The colour is said by Martius (Huechner’s *Repertorium*, Bd. xxxiv. S. 250, 1831) to be between that of galbanum and of violet-root, and to approach that of serpentine; while Geiger considers it to be between that of galbanum and of yellow water iris-root, and similar to myrrh.

3 Ann. du Muséum, xiv. 28; and Ann. de Chimie, lxxvi. 302.

4 *Journ. de Pharm.* (n. s.) xiv. p. 57, 1926.

excitant and diaphoretic. In India, an infusion of it is used as a diaphoretic and gentle stimulant in febrile cases. The warm infusion has been employed as an antispasmodic, diaphoretic, diuretic, and emmenagogue. An ointment of the root has also been applied to destroy pediculi on the heads of children. In 1831, it was used in Paris as a preservative against the cholera: it was worn by the ladies; bundles of it were hung up in the rooms; and fumigations were prepared with it. In Hamburg, it was used by Dr. Buchheister and others in cholera. A weak infusion has been used by Foy in rheumatism and gout. It may be employed in the form of powder, infusion, tincture, or volatile oil. The dose of the powder (pulvis vetiverise) is about a scruple in the form of pills. A weak infusion or tea is prepared with one or two dracontias of the root and two pints of water; this may be drunk ad libitum. A strong infusion, prepared with one ounce of the root to half a pint of water, may be administered in doses of a tablespoonful. A tincture (tinctura vetiverise), made with one ounce of the root and half a pint of proof spirit, is given in doses of a teaspoonful.

42. Andropogon Iwarancusa, Roxburgh.

_Sex. Syst. Triandria, Dignae._

(Radix.)

1 _Iharankwaha, Ierarankwaha, Kurankwaha, Beng. and Hind.; Ierarancusa, Asint. Res. iv. 109; _Terancus,_ Blane, Phil. Trans. vol. _lxx._ p. 286, 1790; Sir G. Blane considered that it might be the _Nardus Indica,_ or _Spikenard_, of the ancients: Mr. Hatchett supposed it to be the source of the _grass oil_ of _Nemaur_, an opinion which Dr. Royle has declared to be incorrect.—This fragrant grass, which has a bitter, warm, pungent taste, is a native of the skirts of the northern mountains of India; between the river Rapti and the northern mountains, and about Hurdwar. It comes remarkably near _A. Schenianthus_ both in habit and taste. It is employed by the natives in fevers, whether continued or intermittent. They infuse about a drachm of it in half a pint of hot water, with a small quantity of pepper, and give this for a dose thrice daily. The virtues almost entirely reside in the larger parts of the roots, marked with annular cicatrizes.

43. Andropogon Calamus aromaticus, Royle.

_Sex. Syst. Triandria, Dignae._

(Oleum volatile.)

According to Dr. Royle, the _grass-oil_ of _Nemaur_ is obtained from a new species of Andropogon, to which he has given the name of _A. Calamus aromaticus_. He says that it is "found in Central India, extends north as far as Delhi, and south to between Godavery and Napore, where, according to Dr. Malcolmson, it is called _spair-grass_: it may be the _A. Martini_ of Roxburgh, as I believe, it is also thought to be by Dr. Wight, though it has been named _A. Nardoides_ by Nees von Esenbeck." Dr. Royle examined Mr. Hatchett's specimens of the grass, obtained from Mr. Swinton, as the source of the grass-oil, and found them to be identical with his _A. Calamus aromaticus_, though Mr. Hatchett's figure of the plant (copied from the Phil. Trans. vol. _lxx._) actually represents another species, viz., _A. Iwarancusa_. Dr. Wallich examined a specimen of the plant from which the grass-oil is obtained, and declared it to be either _A. Iwarancusa_, or, perhaps, _A. Martini_, Roxburgh. Dr. Royle considers this species to be the _sweet calamus_ and _sweet cane_ of Scripture—the _κάλαμος αρωματικός_ of the ancient Greeks.

GRASS-OIL OF _NEMAUD_; _Roosa-ke-tel_, Hind.; _Oleum graminis Indici_.—This oil is imported from India under the name of _grass-oil_ or _ginger-grass oil._

In 1845, I obtained from a merchant in London a sample of essential oil which agreed in its sensible qualities with the grass-oil of Nemaur given me by Dr. Royle. With it I received the following notice: "A sample of three canisters of essential oil imported from Bombay, under the name of _ginger-grass oil_, and, according to the importer, used by the natives against rheu-
Grass-Oil of Nemaups.

155

natism, and by them called *rooa oil* . The grass grows, according to the same authority, fifty or sixty miles from Bombay in the jungle, and is there called *rooa grass*. It smells, as you will perceive, of ginger and turpentine.

Grass-oil of Nemaups is commonly known to the perfumers by the name of *oil of geranium*. I have been informed that it is sometimes called *oil of rose geranium*. It is occasionally sold by druggists as *oil of spikenard*.

Under the name of " *Ol. Palm*, ros," [sic] a volatile oil has been sent from a merchant in Constantinople to his correspondent in London, as an oil used for reducing (that is, adulterating) *otto* of roses; and, in the accompanying letter, it was stated that if genuine *otto* be mixed with from 20 to 30 per cent. of this oil, it would be still equal to the finest commercial *otto*. By the dealers in London this oil was called *oil of geranium*. It is almost colourless, and is clearer, brighter, and more fragrant and roseate than ordinary grass-oil; but its odour is, I think, essentially that of the latter. Is it rectified grass-oil? It is remarkable that Dioscorides (lib. i. cap. xvi.) states that *tyroctos* (a native of Arabia) has the odour of the rose.

Grass-oil of Nemaups is, according to Mr. Forsyth, procured at the foot of the Vindhyas range of hills in the vicinity of Iam Ghaut, and thirty miles further west, near Nalcha.

It is obtained by distillation. When the plant begins to flower, it is cut and bound in small bundles or maniples, 250 or 300 of which are introduced into a wrought-iron boiler fitted over an earthen fireplace. Water being added, ebullition is promoted. The oil, with water, distils into two or three large copper receivers immersed in cold water. The process occupies about six hours. After the product has stood for some time, the oil is skimmed off the surface by a small shallow spoon.

Commercial grass-oil of Nemaups is of a light straw colour, and has a fragrant aromatic roseate odour, with taste which is not very dissimilar to that of oil of lemons. It floats on water. Dr. Stenhouse found that it is usually a mixture of a pure volatile oil (C-H), and of about half its bulk of a fluid resin, the latter probably being the product of the oxidation of the oil.

In India, the grass-oil is frequently adulterated; usually, according to Mr. Forsyth, with the *ol. sesami*. As this is a fixed oil, the sophistication is readily detected by dropping the suspected grass-oil into rectified spirit: if pure, it dissolves, but if it be mixed with a fixed oil, the spirit becomes milky.

Grass-oil is chiefly employed in perfumery; but it is also employed in medicine. Its medicinal properties are similar to those of other aromatic fragrant volatile oils, and are those of a stimulant and diaphoretic. It is highly esteemed in India for the cure of the more chronic forms of rheumatism. It is applied as a liniment. A couple of draughts of it are rubbed into the affected part in the heat of the sun, or before the fire, twice daily. It causes a sense of warmth and pricking which lasts for two hours or longer. It is also employed to excite diaphoresis in slight catarrhal affections; and for this purpose it is rubbed into the soles of the feet and wrists.

44. *Andropogon Schenanni*us, *Linn.*

I suspect that under this name three species of *Andropogon* have been confounded.

1. *Rumphius's Schenanni* Amboincum, called by the natives of Ambayna *Sree*. Its odour is that of a mixture of roses and fresh-mown hay. As Linnæus, in the later editions of his *Systema Plantarum*, cites Rumphius's figure, we may take this species as the genuine *Andro- pogon Schenanni*us of *Linnæus*. It has been recently very fully described by the late celebrated Professor Th. F. L. Nees von Esenbeck. Rumphius proposes to call it *Schenanni Indicum sterculia* , to distinguish it from the Arabian plant.

2. The *Arabian Schenanni*us is said by Hasselquist to grow plentifully in the deserts of both the Arabias, and to be gathered near Limbo, a port of Arabia Petraea, and exported to Egypt. The Arabs call it *Hela Meccavi* and *Idhir Mecci*. It is said that in the deserts between Syria and Egypt there is no grass but this which camels eat: hence it has received the name of *fenum vei stramen camelorum, or camel's hay or straw*. It was formerly in the London Pharma-

---

1 *Reclus* (*Journ. de Pharm.* t. xiii. p. 529, 1827) obtained from Pelargonium odoratissimum, var. odor atros (Peronson), a concrete volatile oil, which he calls *volatile oil of geranium* with the odour of roses (huile volatile du (*geranium à odorat de roses*). It must not be confounded with the so-called oil of *geranium* alluded to in the text.
2 *Transactions of the Medical and Physical Society of Calcutta*, vol. iii. p. 313, Calcutta, 1827.
3 *Herbarium Amboinense*, pars v. lib. viii. cap. 24, page 101, tab. lxxii. Fig. 2.
4 *In the Linnæan Herbarium*, there is a single specimen of *A. Schenanni*, but without any statement indicating its place of growth.
6 *Voyages and Travels in the Levant in the years 1749, 50, 51, 52*, Lond. 1750.—It is remarkable that Forskål, in his *Flora Arabica-Yemen*, does not mention, in his list of odorous plants (p. xev.), a single odorous grass as growing in Arabia Felix.
VEGETABLES.—NAT. ORD. GRAMINEE.

copoesia, and was called schenanthus, squinanthus, vel juncus odoratus; its vernacular name being squinananch or sweet-smelling rush. The herbs (stem, leaves, and sometimes the flowers) were brought from Turkey and Arabia, tied up in bundles about a foot long. The stem, which resembled a barley straw, was filled with a pith like those of our common rushes; the flowers were of a carnation colour, striped with light purple.

It was considered to possess stimulant and diaphoretic properties, and was commended in hiccups, vomiting, flatulent colic, and female obstructions; but was little used, except in the mihradatum and theriac. It was administered to the extent of one or two draehms in the form of infusion or tea.

It is not improbable that this plant may be the σκυίον χόριον of Hippocrates, the σκυίον of Dioscorides for the last-mentioned writer states that the most esteemed sort grew in that part of Arabia called Nabathaec, which agrees with the statement of Hasselquist.

3. The Andropogon citratum, De Cand.—As this is undoubtedly the source of the oil of lemon-grass of the shops, it deserves a separate notice.

45. Andropogon citratum, De Cand.—Lemon-Grass.

Although all the Anglo-Indian botanists, whose works I have consulted, consider the Lemon-grass of India to be identical with the Andropogon Schenanthus of Linnaeus, yet various circumstances have long since led me to suspect that they are in error. Its citron or lemon odour is so very strong and remarkable, that any one familiar with the plant, or its volatile oil, could not overlook or mistake it. Yet not one of the authorities quoted by Linnaeus, nor any of the pharmacologists of the last century who were familiar with the Linnaean plant, mention it. Rumphius, whose figure of the plant is referred to by Linnaeus, says the odour of the Ambonyan plant is similar to that of roses mixed with that of new-mown hay. Dale describes the odour of Schenanthus as being sweet and very fragrant, and Lewis simply says it is agreeable.

The first botanical writer who notices the peculiar citron odour of lemon-grass is De Candolle, who states that under the name of Andropogon citratum there was frequently met with in botanical gardens a grass which had very much the habit of A. Schenanthus, but was larger, did not require a hot-house, and was most distinctly characterized by the citron-odour of the bruised leaves. The late eminent botanist professor Th. Fr. L. Nees von Esenbeck pointed out some botanical characters which distinguish the two plants. Thus he states that the leaves of A. citratum, De Cand. are much broader, flat, of a strong bluish-green colour, and both above and at the margin are very rough when drawn backwards through the fingers; whereas, the leaves of A. Schenanthus are narrow (half a line in breadth), completely keeled, like those of the sedges, bluish-green, and somewhat sharp at the margin when drawn backwards through the fingers. Moreover, the hairs of the rachis of the spikelets of the A. citratum are much shorter than those of A. Schenanthus.

Lemon-grass is a native of the continent of India and of Ceylon. It was introduced into the West Indies towards the latter part of the last, or beginning of the present century.

The peculiar characteristic of this species of Andropogon is its odour, which, when the grass is fresh, is very distinctly citron-like; or rather, especially when the plant is dry, resembles that of balm—the Melissa officinalis, Linn., called by the French Citronnelle.

The lemon-grass yields, by distillation, an essential oil, which is imported from Ceylon, Bombay, Cochin (Malabar coast), and Madras, under the names of lemon-grass oil or citronnelle oil. It is yellow, and has a fragrant, citron-like odour. It is much used in perfumery under the name of oil of verbenas. It is frequently adulterated with a fixed oil, and when thus sophisticated it forms a milky liquid when dropped into rectified spirit; whereas, the pure oil dissolves and yields a transparent solution.

The lemon-grass is employed in the form of infusion, in both the East and West Indies, as a mild diaphoretic in slight colds. The fresh leaves are sometimes used as a substitute for tea, and the white succulent centre of the leaf-bearing stems serves to give an agreeable flavour to curries. In Martinique, it is reputed poisonous, or at least as capable of producing abortion both in animals and the human species.
ORDER VII. CYPERACEÆ, R. Brown.—SEDGES.

Characters.—The plants in this order closely resemble grasses (see ante, p. 106), from which they are distinguished by their embryo being inclosed within the base of the albumen; by their leaf-sheaths being whole or entire, not slit; and by their steams being solid, angular, and without joints or diaphragms.

Properties.—These plants are remarkable for their deficiency of those organic principles which render the grasses so valuable and important to man (see ante, p. 107). The so-called roots (rhizomes) of several species of Cyperus (e. g. longus, rotundus, and esculentus) were formerly employed in medicine. They are mild aromatics, stomachics, and diaphoretics. The roasted roots of C. esculentus have been used as a substitute for coffee. The rhizomes of Carex arenaria have been employed as a substitute for sarsaparilla, under the name of bastard or German sarsaparilla (radix sarsaparilla germanica vel radix graminis major).

Sub-class II. Petaloideæ vel Florideæ.

Characters.—Floral envelopes, if present, whorled. This sub-class includes all the remaining orders of endogens, which may be arranged in two subdivisions.

SUBDIVISION I.

Floral envelopes absent; or, if present, imperfect, squamiform, sometimes more or less glumaceous.

ORDER VIII. AROIDEÆ, Endl. ARACÉE and ORONTIACEÆ, Lindl.

Characters.—Flowers generally unisexual, rarely hermaphroditic, arranged upon a spadix, in the axil of a spathe. Perianth either none, or, in the hermaphroditic flowers, rudimentary and scale.

Stamens numerous, or definite and opposite to the segments of the perianth; anthers opening outwards. Ovaries free, 1, 3, or many-celled. Fruit succulent or dry, indehiscent. Seeds usually with fleshy or mealy albumen, rarely with none. Usually herbaceous plants with either subterranean tubers (cormi) or a creeping rhizome.

Properties.—The fresh plants of this order are frequently remarkable for acridity, which especially resides in the tubers and rhizomes, and often renders them violent poisons. This is especially remarkable in Dieffenbachia Seguinæ, or the Dumb Cane, a native of the West India Islands, two drachms of whose juice have been known to prove fatal in two hours. The acrid principle (which, perhaps, may be a sulphurated volatile oil) is in many cases readily dissipated or decomposed and rendered inert by cooking. Even drying seems to injure or destroy it. As it is soluble in water, washing removes it from the starch.

The useful qualities of the order depend on starch and aromatic volatile oil: on the former depend the esculent properties of some species, and on the latter the medicinal properties of some. Colocasia esculenta (also called Calatium esculentum or Arum esculentum) is used in some parts of the world as food. Its large, fleshy, and farinaceous tubers are called yams in Madeira, from whence they were sent to me by Mr. Nobrega. I find that when boiled they form a very agreeable substitute for potatoes.

Colocasia Antiquorum is cultivated in Egypt and other parts of the world for the nutritious matter yielded by the tubers.

Sub-order I. ARACÉE, Endl.

Flowers naked, unisexual.

46. Arum maoulatum, Linn.—Cuckow-pint.

Sex. Syg. Monoeis, Polyanthera. (Tuber.)

*Arum vulgare, Linn.; Common Cuckow-pint; Wake Robin; Lords and Ladies.—A well-known, indigenous, acid, and poisonous plant, which, by drying or by the aid of hent, loses its acridity. From the underground tubers is manufactured, in the island of Portland, a starch called Portland
arrow-root or Portland sago (secula ari; farina ari). It is procured by cleansing the roots (tubers), pounding them in a stone mortar with water, and then straining. The starch sub-
sides from the strained liquor, and, the supernatant water being poured off, is collected and
dried. Care is requisite in the pounding of the roots on account of their acridity.

From a peck of the roots about a pound of starch is procured.

Portland arrow-root is a white amylaceous powder. Examined by the microscope, its par-
ticles are found to be exceedingly small, circular, mullar-shaped, or polyhedral. The angular
appearance of some of them arises from compression. The hilum is circular, and apparently
lies in a small depression. It cracks in a linear or stellate manner. The dietetical uses of this
starch are similar to those of other starches, as of the West Indian arrow-root. It makes very
agreeable puddings.

The roasted tubers are escalent.

The fresh plant is an acrid poison; causing burning and swelling of the throat, vomiting,
colic, diarrhoea, and convulsions. By drying, the activity of the plant is in a great measure
destroyed. Medicinally, the tubers were formerly used as diuretics in dropships, and as expec-
torants in chronic catarrhs.

47. Arisæm atrimorubens, Blume.—Dragon-Root.

Sex. Syst. Monoeic, Polyandria.

(Tuber.)

Arisæma atrorubens, Blume, Rumphia, i. 97; Arum triphyllum, Linn.; Dragon-root; Indian
Turnip; Wake Robin.—A native of the United States of America. Its properties agree closely
with Arum maculatum, and, like the latter, it yields a pure white secula. The tuber is used
in the United States as a stimulant to the secretions in chronic bronchial affections, rheumatism,
&c., in doses of from ten grains to a scruple. The powder, made into a paste with honey, has
been beneficially applied to the mouth and throat of children in aphthæ.

Sub-order II. CALLACEÆ, Endt.

Perfect stamens associated with ovaries in hermaphrodite florets.

48. ACORUS CALAMUS, Linn.—COMMON SWEET FLAG.

Sex. Syst. Hexandria, Monogynia.

(Rhizoma, L.—Rhizome, E.)

History.—This is probably the ἀκόρον of Dioscorides. Dr. Royle says that in
Persian works ἀκόρον is given as its Greek appellation. It must not be confounded
with the κάλαμος ἀκοματικός of Dioscorides, which, according to Dr. Royle, is
Andropogon Calamus aromaticus, Royle (see ante, p. 154).

Botany. Gen. Char.—Flowers arranged upon a spadix. Spathe replaced by a
two-edged leaf-blade. Perianth of 6 pieces or scales, inferior, persistent. Sta-
mens 6, filiform. Stigma sessile. Ovaries 2-3-celled. Berries 1-celled, 1-
seeded. Seeds albuminous.

Sp. Char.—Spathe, a continuation of the 2-edged scape, rising much above the
spadix.

Rhizome thick, rather spongy, with many long roots, aromatic, like every part
of the herbage, but much more powerfully so. Leaves erect, two or three feet

2 The following measurements of five particles were made by Mr. Jackson:

The average size, therefore, is the \(\frac{3}{4}\) of the inch in diameter.

p. 387.
4 Lib. i, cap. 2.
high, bright green, near an inch broad. Stalk like the leaves, except being thicker below the spadix, and not quite so tall. Spadix about a foot above the root, a little spreading, two or three inches long, tapering, covered with a mass of very numerous, thick-set, pale green flowers, which have no scent, except when bruised. A very narrow wavy membrane may be observed at the base of the spadix, which perhaps ought to be taken into the generic character as a spathe (Smith).—Perennial: flowers in June.

Hab.—It is a native of this country, growing in watery places about the banks of rivers, and is very plentiful in the rivers of Norfolk, whence the London market was formerly supplied. It grows, also, in other countries of Europe, in Asia, and in the United States.

Description.—The dried underground stem (rhizoma, L; radix acori veri seu radix calami aromatix, Offic.) occurs in the shops in flattened pieces four or five or more inches long, and about as broad as the thumb; jointed, somewhat curved, of a spongy or corky texture internally; of a yellowish brown or fawn colour externally, and buffy, with a slight roseate hue, internally. Their fracture is short: their upper surface is marked transversely with the vestiges of the leaves which were attached to it; the lower surface has numerous dark points, surrounded by small light-coloured elevated circles, from which the roots arise. Their taste is warm and bitter; their odour is aromatic. In Germany, the rhizome is usually peeled before drying it (rhizoma decorticata); but the operation is unnecessary and wasteful. In this state, the rhizome is grayish-white and easily pulverizable.

The rhizome should be gathered in spring or late in the autumn, and dried quickly. It is usually gathered on the banks of the Thames about May for the London market.

The fresh rhizome is employed for distillation. The pieces are sometimes fourteen or fifteen inches long, and one inch wide.

The rhizome of the Yellow Water Iris (Iris Pseudo-acorus) is said to be sometimes substituted for that of the true Acorus.

Composition.—The fresh rhizome was analyzed by trommsdorff, who obtained the following results: Volatile oil, 0.1; soft resin, 2.3; extractive, with a little chloride of potassium, 3.3; gum, with some phosphate of potash, 5.5; starchy matter (like inulin), 1.6; woody fibre, 21.5; and water, 65.7. Meissner found traces of copper in the ashes.

The active constituents are the oil, the resin, and the extractive.

Oil of the Common Sweet Flag (oleum acori calami; called, in the shops, oleum calami aromatix) is obtained by distilling the fresh rhizome with water. Its odour is similar to, though less agreeable than, that of the rhizome. Its colour is yellow. It is bought by snuffmakers, so that it is used, I presume, for scenting snuff. It is also employed in the preparation of aromatic vinegar.

Chemical Characteristics.—Iodine blackens the rhizome (especially when it has been boiled), thereby indicating the presence of starch. The cold decoction of the rhizome forms, with a solution of iodine, the blue iodide of starch. Acetate and diacetate of lead, and protonitrate of mercury, cause precipitates with the decoction. These precipitates consist principally of metallic oxides or subsalts, and the substance called extractive. Nitrate of silver produces a precipitate (chloride of silver), which is insoluble in nitric acid, but soluble in ammonia. The decoction reddens litmus.

Physiological Effects.—It is an aromatic stimulant and mild tonic. Vogt* arranges it with the excitantia volatilia, and regards it as approaching angelica root on the one hand, and cascarrilla and angustura barks on the other.

Uses.—It is rarely employed by medical practitioners, though it might be frequently substituted, with good effect, for the more costly oriental aromatics. It is a useful adjunct to other stimulants and tonics. It has been employed in continued

---

Asthemic fevers accompanied with much prostration of strength and greatly weakened digestive power. For the cure of ague, the dried root powdered is used by the country people in Norfolk.1 It is well adapted for dyspeptic cases accompanied with, or dependent on, an atomic condition of the digestive organs, and is especially serviceable in gouty subjects. It has also been used as a local agent, viz., in the formation of aromatic baths, poultices, and gargles, as an application to foul-conditioned ulcers, &c. It is employed, I am informed, by some rectifiers to flavour gin.

Administration.—In powder, the rhizome may be given in doses of from a scruple to a drachm. The infusion is, perhaps, the most eligible preparation; it is made by digesting $\frac{3}{4}$ of the rhizome in $\frac{3}{4}$ j of boiling water; the dose is two or three tablespoonfuls. The decoction is an objectionable preparation, as the oil of the rhizome is dissipated by boiling. The tincture (Ph. Bor.) is procured by digesting $\frac{3}{4}$ of the rhizome in $\frac{3}{4}$ j of spirit (sp. gr. 0.900); the dose is a teaspoonful.

SUBDIVISION II.

Flowers with a proper, often corolline perianth, usually hermaphrodite.

1. Leaves with parallel veins, either proceeding from the base to the apex (straight-veined), or curved and proceeding from the midrib to the margin (curved-veined).

† Flowers sessile on a branched scaly spadix, usually unisexual.

ORDER IX. PALMAE, Juss.—THE PALM TRIBE.

Palmaceae, Lindl.

Characters.—Flowers hermaphrodite, or frequently polygamous. Perianth six-parted, in two series, persistent; the three outer segments often smaller, the inner sometimes deeply connate. Stamens inserted into the base of the perianth, usually definite in number, opposite the segments of the perianth, to which they are equal in number, seldom three; sometimes, in a few polygamous genera, indefinite in number. Ovary one, three-celled, or deeply three-lobed; the lobes or cells one-seeded, with an erect ovule, rarely one-seeded. Fruit baccate or drupaceous, with fibrous flesh. Albumen cartilaginous, and either ruminate or furnished with a central or ventral cavity; embryo lodged in a particular cavity of the albumen, usually at a distance from the hilum, dorsal, and indicated by a little nipple, taper or pulley-shaped; pith and endosperm included, scarcely visible; the cotyledonous extremity becoming thickened in germination, and either filling up a pre-existing cavity, or one formed by the liquefaction of the albumen in the centre.—Trunk arborescent, simple, occasionally shrubby and branched, rough, with the dilated half-sheathing bases of the leaves or their scars. Leaves clustered, terminal, very large, pinnate, or flabelliform, plaited in vernalion. Spadix terminal, often branched, enclosed in a one or many-valved spathe. Flowers small, with bractlets. Fruit occasionally very large. (R. Brown, 1810.)

Properties.—Palm, considered in a dietetical and medicinal point of view, are of the highest importance to the inhabitants of tropical regions. Their stems yield starch (sago) sugar, and wax; their terminal leaf buds are boiled and eaten as a kind of cabbage; their fruits yield oil, sugar, and resins; and their seeds form articles of food, and yield, by pressure, fixed oil.

In the abundance of sugar and starch which the palms yield, this family resembles the grasses. But they are distinguished from the latter in containing, in some cases, a large quantity of fixed oil. To these three principles are chiefly due the nutritive qualities of palms. But these substances being non-nitrogenized, are merely fat-making and heat-yielding, and without the addition of protein compounds (found in the seeds, and probably in other edible parts of palms), would be insufficient to support life.

Palm sugar, in the crude state, is called jaggary. By fermentation, it yields toddy or palm wine, from which, by distillation, an ardent spirit (arrack or rack) is obtained. Date sugar, and also other kinds of palm sugar, are imported into England, and are used by grocers for mixing; but, being deficient in what in trade is called "strength," they do not pay for refining.2 Wax, astringent matter (tannin), and resins, are useful products obtained from palms, but they are of less frequent occurrence than the substances before mentioned. Still less frequently met with are acid principles.

The ashes obtained by the combustion of palm leaves yield potash.

1 Sir J. E. Smith, Engl. Flora, ii. 158.
1. PAlMÆ FARINIFERÆ.—SAGO PALMS.

The farinaceous substance called sago is obtained from the stems of several palms. Those of the genera Sagus and Soqeurus are the most important, and will be separately noticed.

The trunk of old trees of Caryota urens, called, by Robinson, the Sago palm of Assam, yields a sago which both Roxburgh and Robinson consider to be very little if at all inferior to the sago of the Malay countries. From Phoenix farinifera, which grows in the Coromandel coast, is likewise obtained a sago, but which is less nutritious and palatable than the common sago. Corypha umbraculifera, or the Talipat palm, yields sago in Ceylon; which would appear from the statement of Bennett to be of inferior quality.

Japan Sago is said to be obtained from several species of Cycas. None of this, however, reaches England. (See order Cycadeæ.)

49. SAGUS, Gartner.
Sex. Syst. Monococia, Hexandria.

Metrozylon, Rotb.

Stem tallish. Petioles, rachides, and spathes, unarmed. Fruit somewhat globose, and depressed on both sides. (Blume, in Rumphia, p. 147.)

Islands of the Indian Archipelago, Sumatra and Borneo, and the islands between them, growing spontaneously in low swampy lands.

A large quantity of granular sago is prepared from this species in Sumatra especially, the peninsula of Malacca, and in Borneo. It is chiefly exported to Europe, Bengal, and China. The farina which is brought from Siak, on the northern coast of Sumatra, although inferior in whiteness to that of Borneo, is much sought after on account of its being less friable. It commonly fetches twice the price of the latter.

The quantity of sago yielded by this palm is prodigious: Crawford says 500 or 600 lbs. is not an unusual produce for one tree: and Blume mentions 600 to 800 lbs. as the quantity obtained from a single tree when mature.

Stem of middling height. Petioles, rachides, and spathes prickly; the prickles scattered or confluent. Fruit somewhat globose, depressed on both sides. (Blume.)

---

3 Ceylon, and its Capabilities, p. 95, Lond. 1813.
4 Rothb (Flora Indica, vol. iii. p. 523) says that from the pith of this tree the granulated sago which we meet with in Europe is made.
5 Blume, Rumphia, vol. ii. p. 149.
Islands of the Indian Archipelago. Abounds in the Malacca islands, especially where the nutmeg and clove grow naturally.

"This, the Malay Sago Palm, is the tree the pith of which is the staff of life to the inhabitants of the Moluccas." (Roxburgh.)

The stature of this tree seldom exceeds thirty feet. Before maturity, and previous to the formation of the fruit, the stem consists of a thin hard wall, about two inches thick, and of an enormous volume of tissue (commonly termed the medulla or pith), from which the farina, called sago, is obtained. As the fruit forms, the farinaceous medulla disappears; and when the tree attains full maturity, the stem is no more than a hollow shell. The utmost age of the tree does not exceed thirty years.1

50. SAGUERUS SACCHARIFER, Blume.—THE GOMUTO PALM.

Sex. Syst. Monoeia, Polyandria.

BOTANY. Gen. Char.—Flowers monoeicous by abortion, on separate spadices, sessile, the female ones between two males. Spadices simply branched. Spathes many incomplete. Calyx 3-cleft, with imbricated leaflets. Corolla 3-petalous, with valvate aestivation. Males: Stamens indefinite; filaments filiform: anthers linear, cuspidate. Females: Ovary trilocular, with the Ovule affixed at the bottom of the internal angle. Stigmata 3, acute, connivent. Berry 3- or, by abortion, 2-seeded. Albumen uniform. Embryo dorsal. (Blume.)

Sp. Char.—Petioles unarmed. Segments of the fronds linear-lanceolate, at the base 1- or sub-2-auriculate, beneath whitish. Branches of the spadices elongated, fastigiate, pendulous. Berry turbinate-globose. (Blume.)—From 20 to 25 feet high: readily distinguished by its rude and wild aspect.

Hab.—Very common in the islands of the Indian Archipelago, the Moluccas, and the Philippines.

A saccharine juice called nēra or toddy is obtained in large quantities by wound- ing the spadices and receiving the liquor in earthenware pots or bamboo closely fastened beneath.2 This juice yields by boiling a coarse dark kind of sugar (jaggary), and by fermentation an intoxicating beverage. Wine which is used by the Chinese residing in the Indian islands in the preparation of Batavian arrack.3 When the trees are exhausted by the incessant draining of their juices, sago of good quality is obtained from the trunk—as much as 150 to 200 lbs. weight from a single tree.4

The flesh of the fruit is acrid, and affords a juice which when applied to the skin occasions great pain and inflammation. The inhabitants of the Moluccas were in the practice of using in their wars, in the defence of posts, a liquor afforded by the maceration of the fruit, which the Dutch denominated hell water (aqua infernalis).5

SAVO.

(Sago; Sagualavis, Rumph., et alia fortasse Palmarum species. Caudicis Facula, L.)

HISTORY.—Sago does not appear to have been known to the Greeks, Romans, or Arabians. The preparation of sago-meal and sago-bread, as carried on at Fanfur

3 Crawford’s History of the Indian Archipelago, vol. i. p. 399, 1820.
5 Crawford, op. cit.
Sago:—Commerce; Manufacture.

163

(Kampar, in Sumatra?), was first described by Marco Polo in the 13th century. Sago-bread was described and figured by Clusius.1

Granulated sago was not known until a later period. It is said2 to have been introduced into England in 1729, into France in 1740, and into Germany in 1744. Rumphius4 states that in Borneo grains of the size of a coriander seed are made from the farina of the Saguereus (Saguereus saccharifer, Blume).

The word sago (also written by some of the earlier authors zahu and sasa5) is the Malay name both for the palm and its farina:6 it is also used in Java to signify the bread made from the farina.7

Commerce.—Sago is brought to England from Singapore in bags, &c. The quantity on which duty was paid in 1840 was 26,895 cwts.

Newbold8 gives the following as the quantities imported into Singapore in 1836:

<table>
<thead>

</table>

The quantity exported from Singapore in the same year was 28,764 piculs.

Manufacture. a. Of Raw Sago-Meal.—The manufacture of sago-meal varies somewhat in different localities. In the Moluccas, it is procured as follows: When the tree is sufficiently mature, it is cut down near the root, and the trunk subdivided into portions of six or seven feet long, each of which is split into two parts. From these the medullary matter is extracted, and with an instrument of bamboo or hard wood is reduced to powder, like sawdust. To separate the farina from the accompanying bran and filaments, it is mixed with water, and the mixture then strained by a sieve. The strained liquor deposits the farina, which, after two or more edulations, is fit for use. This is raw sago-meal.9

b. Of Sago-Bread.—In the Moluccas, sago-cakes are made by throwing the dry meal into heated earthenware moulds: a hard cake is formed in a few minutes, so that one heating of the mould serves to bake several series of cakes.10

c. Of Granulated Sago.—To prepare this the meal is mixed with water and made into a paste, which is then granulated. Forrest says that in New Guinea granulated sago is made by mixing the sago-meal with water and passing the paste through a sieve into a very shallow iron pot held over a fire, by which it is made to assume a globular form; so that, he adds, our grain sago is half baked and will keep long. This, according to Blume, is the process which is followed by the Chinese colony in Singapore; the meal being first repeatedly worked and dried. Blume adds that, during the heating process, the grains are constantly turned, and that, though quite white at the commencement, they become hard and somewhat pelliced during the process.

One kind of pearl sago of the shops has been obviously subjected to some heating process: this is the Tapioka sago of Guibourt; but the application of heat must have been most carefully regulated, for charred sago is unknown to commerce. Some of the granulated sago of the

2 Exotic. lib. i. cap. iii. p. 3, 1605.
4 Herbarium Amboin. para lina, p. 64, Amst. 1750. 5... in Borneo ex cedam confidenti farina rotunda grana Coreanidri somen magnitude et forma referentia. I have given the words of Rumphius, because some highly respectable authorities (J. A. Murray and Guibourt) have overlooked this passage, and assumed that Rumphius does not mention granulated sago.
5 See the authorities quoted in C. Buxhin's Pinar.
7 Sir F. Drake, in Hakluyt's Principal Navigations, Voyages, &c. vol. iii. p. 732.
8 Political and Statistical Account of the British Settlements in the Straits of Malacca, vol. i. p. 301, Lond. 1839.
9 Crawford, op. supra cit. vol. i. p. 390. Mr. Crisp (Asia. Researches, vol. vi. 1790) has described the mode of preparing sago-meal in the Hoggery Islands, lying off Sumatra. See, also, Forrest's Voyage to New Guinea, 2d edit. 1789, pp. 30-41, for the method of preparing it by the Papuans.
10 Forrest (op. supra cit.) has figured a mould, which he calls the Papuan oven.
shops presents no evidence of having been heated; and it has, therefore, been supposed that its granulation must have been effected by a mill.

Description of Sago.—Sago occurs in commerce in two states—pulverulent and granulated.

1. Pulverulent Sago; Sago Meal; Sago Flour (Farina Sagi).—This is imported in the form of a fine amylaceous powder. It is whitish, with a buffy or reddish tint. Its odour is faint, but somewhat unpleasant and musty. Viewed by a powerful pocket-lens, it presents a glistening granular appearance. Examined by the microscope, it is found to consist of irregularly elliptical or oval, more or less ovate, usually isolated particles, which are often somewhat narrowed or tapered at one extremity. Owing to their mutual pressure, many of them appear as if truncated, either by a single plane perpendicular to the axis of the particle, in which they are more or less mullar-shaped—or by two inclined planes, giving the particles a dihedral extremity. Some of them resemble in form a caoutchouc bottle cut off at the neck. From their strong lateral shading they are obviously convex. Many of the particles are more or less broken. Most of them have an irregular or tuberculated surface, as if eroded. The hilum, when perfect, is circular; but it cracks in the form of a single slit, or of a cross, or in a stellate manner. The surface of the particles presents the appearance of a series of concentric rings or annular lines, which, however, are much less distinct than in potato starch. These lines are indicative of the concentric layers of which each particle is composed. When examined by the polarizing microscope, the particles show a black cross, the centre of which is the hilum.

I have met with sago-meal in commerce under different names. Once, I received a sample from Cockermouth, in Cumberland, where it was sold as “Food for the People.” A sample of a fine white and carefully-prepared sago-meal was given me under the name of arrow-root. I shall distinguish it as refined sago-meal.

The following information respecting the mode of refining sago-meal was furnished me by a starch manufacturer: “By sifting and washing, the best sago-meal loses about one-fifth of its weight in the form of earthy matter and woody fibre. The meal thus sifted and washed is then bleached by means of chloride of lime and sulphuric acid. The bleached meal is afterwards washed in successive waters until a perfectly pure product is obtained. In this state it serves as a food for infants and invalids. Coloured by turmeric, and flavoured by the essential oils of cassia and bitter almonds, it forms a custard powder. Without the colouring matter, it serves as a blanc-mange powder.”

2. Granulated Sago; Grain Sago (Sagus granulosa); Grana Sagi.—The grains are more or less rounded masses of variable size and colour. Examined by a microscope with a low object-glass (say of 2- or 3-inch focus), they are seen to be masses of glistening particles. There are two kinds of granulated sago—brown sago, and pearl sago.

a. Common or Brown Sago (Sagus fusca); Sagu gr"is des Moluques, Planche and Guibourt.—This is the only kind of sago which was known in English commerce prior to the introduction of pearl sago.

\end{array}\]
It occurs in somewhat irregularly-rounded or globular masses or grains, which are whitish on one side, and grayish-brown on the other. The ordinary brown sago of the shops consists of grains which are usually about the size of the grains of pearl barley. This may be termed the smaller or ordinary brown sago. It is the sago gris des Moluques of both Planche and Guibourt. But there is another variety, the globular masses of which are larger, sometimes as large as gray peas. To distinguish it from the smaller sort just mentioned, I shall call it large brown sago. I received it first from Dr. Douglas Maclagan, of Edinburgh, and subsequently from Professor Guibourt, who terms it gros sago gris des Moluques. The smaller masses of it are about equal in size to the larger masses of the former sort of brown sago. Except in the size of the grains or masses, the two sorts are identical.

Examined by the microscope, the grains of brown sago are found to consist of particles like those of sago-meal, but somewhat more broken and less regular in their shape. Some of them present the appearance of containing in their interior a smaller particle, or rather, perhaps, an air-cavity, which, when examined by polarized light, forms the centre of the black cross. Intermixed with the starch particles is a yellowish-brown substance, which gives colour to the sago.

3. Pearl Sago (Sagus perlata).—The manufacture of this kind of sago is comparatively recent. Crawfurdo, who wrote in 1820, says: "Within the last few years the Chinese of Malacca have invented a process by which they refine sago so as to give it a fine pearly lustre. . . . A small quantity of it, exposed for sale in the London market in 1818, sold for about thrice the price of ordinary [that is, brown] sago." The sago used by the Chinese at Malacca in the manufacture of pearl sago is, according to Newbold, brought from Sumatra. Pearl sago is also prepared at Singapore.²

Pearl sago occurs in pearl-like grains, which vary in size from that of poppy seeds to that of white mustard seeds, or even somewhat larger than these. The shape of the larger grains is more or less globular, that of the smaller ones being often much less regular. The surface of the larger grains is smooth, even, and regular; that of the small grains often rough, uneven, and somewhat tuberculated. Occasionally, two or three of the smaller grains adhere together. Some samples are white, some brownish yellow, pink, or roseate. The coloured grains are not of uniform tint over the whole of their surface; often being on one side white, on the other coloured. By the aid of a solution of chloride of lime, the coloured kinds can be bleached and rendered perfectly white (bleached pearl sago).

When submitted to microscopic examination, pearl sago is found to consist of the same kind of starch particles as sago-meal, but all more or less ruptured, and presenting indistinct traces of rings. These peculiarities are doubtless produced by the process of granulation.

aa. White Pearl Sago.—Grains smaller than white mustard seeds; opaque and white on one side, pearly on the other. The filtered cold aqueous infusion does not strike a blue colour with tincture of iodine. The whiteness of this kind of pearl sago has probably been produced by bleaching.

ββ. Coloured pearl sago.—Grains of different size. Those of some sorts are not larger than poppy seeds (small coloured pearl sago), while those of other sorts are nearly as large, or even somewhat larger, than white mustard seeds (large coloured pearl sago). The colour varies in intensity, and slightly in shade also; but the prevailing tint is that of bran, or sometimes pinkish brownish yellow. Some sorts are as pale as ground, unsifted wheat-flour (pale-coloured pearl sago); others are nearly as deep-coloured as bran itself. Some of the larger sorts have a grayish or brownish colour (grayish or brownish pearl sago); but, like all kinds of coloured

sago, the tint is not uniform on different parts of the same grain, being deep on one side and pale on the other.

The filtered cold aqueous infusion of some sorts does not strike a blue colour with tincture of iodine. This kind corresponds to the *Sagou rosé des Moluques* of Planche and Guibourt.

The filtered cold aqueous infusion of other sorts yields a blue colour on the addition of tincture of iodine, showing that a higher temperature has been employed in the preparation of it than of other sorts. This corresponds to the *Sagou-tapioka* or *Tapioca-sago* of Guibourt. When examined by the microscope, the particles are found to be more ruptured and torn—an obvious effect of heat on them. This sort of pearl sago is often not distinguishable by its external appearance from that of the *Sagou rosé des Moluques* of Planche and Guibourt.

Under the name of *damaged pearl sago*, I have received a sample of coloured pearl sago, some of the particles of which are yellow (from sulphur-yellow to orange coloured). When bleached by means of chloride of lime, it becomes quite white (*bleached pearl sago*).

**Factitious Sago.**—This is prepared in both Germany and in France (at Gentilly, near Paris) with potato-starch. It occurs both white and coloured.

I have two kinds of *white factitious sago*—one small-grained, the grains of which are scarcely so large as white mustard seeds; the other large-grained, the grains of which are intermediate in size between white mustard seeds and coriander seeds. The first, I met with in English commerce; for the other, I am indebted to Professor Guibourt.

I have also two kinds of *coloured factitious sago*, both large-grained—one red, the other brownish, and somewhat resembling brownish pearl sago. For both of these I am indebted to Professor Guibourt.

The white and the red sorts are remarkable for being spherical and smooth.

The microscope can alone distinguish factitious sago from the real sort. The difference in the size, the shape, and other characters, between the particles of sago-starch and the unaltered particles of potato-starch, readily distinguish the one from the other. (See also *Potato-starch.*

But many of the starch particles of potato sago are ruptured by the influences to which they have been subjected during the preparation of the sago. They have become swollen, ruptured in the direction of their long axis, and, by drying, have shrivelled, leaving a long, linear, sometimes curved or even-branched line with incurved or involuted edges, indicating the situation of the rupture.

I have received from Professor Guibourt samples of "Sagou des Maldives* of Planche, donné par lui," and "Sagou de la Nouvelle Guinée* de Planche, donné par lui," and find them to be factitious sagoes made from potato-starch. The grains of New Guinea sago are undistinguishable externally, and, by the microscopic examination of their starch particles, form red-coloured "Sagou de fécule de pomme de terre," which sent me by Professor Guibourt. Both are bright red on one side and whitish on the other. Most of their starch grains are ruptured and shrivelled as above described. The Maldivc Sago is paler coloured, and some of its starch particles are little or not at all altered; others are ruptured and shrivelled.

**Composition.**—Sago has not been analyzed. The pure starch, of which it essentially consists, doubtless has the same composition as other amylaceous substances, viz., $\text{C}_{6}\text{H}_{10}\text{O}_{5}$. Sago-meal is contaminated with various impurities (see ante, p. 164). Granulated sago contains some colouring matter, particles of which may readily be detected by the microscope.

**Chemical Characteristics.**—Sago possesses the general characters of an amylaceous substance.

*Sago-meal* is insoluble in cold water; but, by boiling in water, it almost entirely

---

1 This is, perhaps, the kind mentioned by Planche (*Journ. de Pharm.* t. xxiii. p. 305, 1837) as being "falsified sago coloured by cochineal."  

2 This, perhaps, is the brown sort of German sago made from potato-starch, and said, by Dierbach (Synopsis Materiae Medicae, Abt. i. S. 37, 1841), to be coloured by burnt sugar.  

3 *Journ. de Pharm.* tom. xxiii. p. 156, 1837.
dissolves, and yields a tolerably clear solution. The decoction, when cold, strikes a blue colour with tincture of iodyne.

Granulated sago swells up in cold water, but does not completely dissolve by boiling, a more or less considerable amount of insoluble matter remaining behind. The remarkable difference in the action of boiling water on sago-meal, and on different kinds of granulated sago, leads me to suspect that some substance of difficult solubility in water is used in the preparation of the paste for making granulated sago. The filtered cold aqueous infusion of some sorts of pearl sago (Sagou-tapioka of Guibourt) strikes a blue colour with tincture of iodyne. The cold infusion of brown sago is rendered milky by nitrate of silver, diacetate of lead, and protionate of mercury; but the cold infusions of pulverulent and of pearl sago are scarcely affected by these tests.

Physiological Effects.—It is nutritive and easy of digestion, and is an important article of food in some parts of the East. *The Malay sago palm,* says Dr. Roxburgh, *is the tree, the pith of which is the staff of life to the inhabitants of the Moluccas.* It is probable that this pith contains some nitrogenized nutritive substance in addition to the amylaceous matter.

Uses.—Sago puddings are occasionally brought to table. But the principal use of sago is to yield a light, nutritious, easily-digestible, and non-irritating article of food for the invalid in febrile and inflammatory cases. For this purpose it should be boiled in water (in some cases milk is preferred), the solution strained, and flavoured with sugar and spices, or even with a little white wine, when the use of this is not contraindicated.

2. Palmae Oleiferae.—Oil Palms.

Oil is obtained from the fruit of some, and from the seeds of many palms. Two oils obtained from palms are found in commerce: they are palm oil and cocoa-nut oil; the one obtained from a species of Elaeis, the other from a Cocos.

51. Elaeis, Jacquin.—The Guinea Oil Palms.

Sex. Syst. Dimelia, Hexandria.

(Fructus oleum.)

Palm oil is obtained from two species of Elaeis, both natives of Guinea, and to both of which the name of Guinea Oil Palm is equally applicable. The oil resides in the fleshy portion of the fruit, which, in this respect, resembles the olive.

1. Elaeis guineensis, Jacquin; The True Guinea Oil Palm; The Palm Oil-Tree; Sloane's Jamaica, vol. ii. p. 113, 1725; Avorla, Aubl., Pl. de la Guiane, 1775.—A native of Guinea; cultivated in tropical America. The drupes are about the size of pigeons' eggs, ovate, somewhat angular, deep orange yellow, collected in heads. They have a thin epicarp, a fibrous, oily, yellow sarcocarp, which covers and closely adheres to the hard stony putamen or endocarp, within which is the seed.

From the sarcocarp is procured palm oil (oleum palmae). This is obtained by boiling the pulp in water, by which the oil separates and floats on the surface.

2. Elaeis melanoococa, Gartn.—The drupes are somewhat smaller than those of the preceding species. Some time since I received from Mr. Warrington a bunch of them, which had been recently brought from Guinea as the fruit from which palm oil is obtained. The flesh of the fruit is oily, and has the well-known colour and colour of palm oil. Gartn thought that it might be only a variety of E. guineensis; but Von Marius, who has fully described it, regards it as a distinct species.

At the ordinary temperatures of this country, it is solid, and might, therefore, with more propriety be termed palm butter. It is said that, when quite fresh, it fuses at 81° F.; but that, by keeping, its fusion point rises. Stenhouse found that very old palm oil required a temperature of 83° F. to fuse it.

Palm oil has a rich orange yellow colour, a sweetish taste, and an agreeable odour resembling

---

1 De Fructibus et Semin. Plant. vol. i. p. 18, 1801.
3 Palmae Brasil. p. 62, tab. 54-56.
that of the rhizome of the Florentine orris. It is soluble in boiling alcohol and in ether. By exposure to solar light it becomes white.

Palm oil requires to be bleached for various uses in the arts, and there are several agents which are used for decolorizing it—viz., chlorine, oxygen, powerful acids (sulphuric, nitric, or chromic acid), and the combined influence of air, heat, and light.

Palm oil consists of oleine, palmitine, and colouring matter. As found in commerce, it usually contains also free fatty acids (oleic and palmitic) and free glycerine, and, therefore, may be said to be rancid. The cause of the separation of these acids from the glycerine has not been satisfactorily explained. The quantity of them increases with the age of the oil, and, according to Pelouze and Boudet,\(^1\) varies from 33 to 80 per cent. of the entire oil. In proportion as the quantity increases, the fusing point of the oil rises. The glycerine which is set free gradually becomes converted into sebacic acid, which is also found in old palm oil. These various changes seem to be effected by a kind of fermentation, to the commencement of which, according to Gubourt,\(^2\) the presence of atmospheric air is necessary.

Palmitine is a white solid fat, which is resolved, by saponification and by the fermentation just alluded to, into palmitic acid \((\text{C}_6\text{H}_{12}\text{O}_2\text{O}^+\text{HO})\), considered by Dumas to be identical with ethalic acid—and glycerine (oxide of glycerate).

The Africans use palm oil as a kind of butter. It is now rarely employed in medicine. By the public it is occasionally used by way of friction in bruises, sprains, &c. It is a constituent of the common black bougie. Its ordinary use in this country is in the manufacture of soap and candles. It readily becomes rancid.

The seeds of both species of Elaís are nutritious. They yield by pressure a fixed oil \((\text{palm} \text{-seed} \text{oil}; \text{oleum} \text{palma} \text{seminis})\), which is solid at ordinary temperature. It is devoid of the orange-yellow colour and orris odour of palm oil. It is said to be used in Africa as a kind of butter. It is rarely brought to Europe, but for a few years since I obtained from Africa a specimen of it, with a sample of the seeds from which it was procured.

52. Cocos nucifera, Linn.—The Cocoa-Nut Tree.

**Sec. Syst. Monocela, Hexandria.**

(Semina.)

Tenga, Rheede, Hort. Malab. i. t. 1, 2, 3, 4; Calappa, Rumph, Herb. Amb. i. t. 1, 2.—A native of tropical countries, but does not thrive except near the coast. It is one of the most important and valuable palms. Five varieties of it are indigenous to Ceylon.\(^3\) Its stem yields porcupine wood. A powerful oil is extracted from the bark, which is used by the Cingalese in the form of ointment in cutaneous diseases. By incision into the spathe at the top of the leaves, sweet toddy is obtained, which, by fermentation, yields palm wine, from which arrack is procured by distillation. The fruit, the cocoa-nut in the shell of the shops, is a drupe, the fibrous portion of which yields coir, which is used for making ropes, mats, &c.; and is also employed, as a substitute for horse-hair, for stuffing mattresses. Within the cocoa-nut is the nucleus or kernel (in the dried state called copra in commerce), consisting of the albumen (the edible portion), within which is the unsolidified liquor amnii (called cocoa-nut milk) and the embryo, which is lodged in a small cavity at the base of the albumen. The albumen and cocoa-nut milk have been analysed by Brandes,\(^4\) Buchner,\(^5\) and Bizio.\(^6\) According to the latter authority, 100 parts of cocoa-nut milk contain—water, 95; crystallizable glycerine (identical with cocine and granatine), 3.825; zymome, 0.75; and mucilage, 0.25 [loss, 0.175]. In 100 parts of the albumen, he found—71.488 of oil; 7.665 of zymome; 3.588 of mucilage; 1.595 of crystallizable glycerine; 0.325 of yellow colouring matter; and 14.950 of woody fibre [loss, 0.392]. There are two modes, practiced at Malabar and Ceylon, of obtaining cocoa-nut oil or oleum cocoa-nut butter: the one is by pressure, the other by boiling the bruised nut and skimming off the oil as it forms on the surface. It is a white solid, having a peculiar odour, like that of the flowers of furze \((Ulex europaeus)\), and a mild taste. It fuses at a little above 70° F., readily becomes rancid, and dissolved easily in alcohol. It consists of a solid fat called cocin or cocinone \((a\) combination of glycerine and cocine or coco-steaenic acid, \(\text{C}_6\text{H}_{12}\text{O}_2\text{O}^+\text{2HO})\), and of a liquid fat or oleine, which has not been much examined. Cocoa-nut oil is used in the manufacture of candles and soap.\(^7\) It serves particularly for the manufacture of marine soap, which forms a lather with sea-water. Cocoa-nut oil has been used for medicinal purposes. Loureiro considered it, when fresh, not inferior to olive oil. On the continent of India, as well as in Ceylon, it is used as a pomatum for promoting, preserving, and softening the hair. Mr. Bennett thinks that if it were perfumed, and used for this purpose by Europeans, it would soon display its virtues to such advantage as

5 Knapp's Chemical Technology, vol. i. p. 468, 1848.
to ensure its general use. But the great drawback to its medicinal employment in pomatums and ungues is its odour, and the facility with which it becomes rancid.

3. Palma Ceriferæ.—Wax-bearing Palms.

The only palm wax which has been brought to Europe as an article of commerce is the produce of the following palm—

_Corypha ceriferæ_, Mart. Gen. et Sp. Palm. tab. 49 and 50; _Carnauba_, and _Ananachi cariri_, Piso et Marcgrave, pp. 62 and 130, 1643; _Carnauba_, Brande, Phil. Trans. 1811, and Virrey, Journ. de Pharm. LXX. p. 112, 1834.—Grows on the shores of the Rio Francisco, in the Brazils. 1

In the axilae of the leaves, waxy scales are secreted, which are collected and melted by the Indians. The wax thus obtained is imported into this country from Rio Janeiro under the names of _Carnauba Wax_, _Brazilian Wax_, or _Palm Wax_. It was submitted to chemical examination by Mr. Brande, and has subsequently been analyzed by Lewy, who found it to consist of _C_9_H_20_O_4_. The fusing point of this wax is 180°. It is, therefore, less fusible than bees' wax, whose melting point is about 150°. Being a genuine wax, it is applicable to some of the purposes for which common bees' wax is now employed.

4. Palmae resiniferae.—Resin-bearing Palms.

The only resinous substance used in medicine and the arts, and which is obtained from the palms, is Dragon's blood, the produce of _Calamus Draco_.

53. Calamus Draco, Wildd.—The Dragon's Blood Calamus.

_Sex. Syst. Diocèse, Hexandria._

(Resina; _Sanguis Draconis._)

_Palma Juncus Draco_, Rumph., Herb. Amb. pars v. p. 114, t. lviii. Fig. 1.—A native of the islands of the Indian Archipelago. The berry, which is round, pointed, and about the size of a cherry, yields a resinous substance called in commerce _dragon's blood_ (_sanguis draconis_)—a term which is also applied to a product of the _Dracena Draco_ (vide _Liliacea_). It is also, according to a substance obtained from the _Pterocarpus Draco_ (vide _Leguminosæ_), Lieut. Wellstead says that, in Socotra, Dragon's blood exudes spontaneously from the stem of a tree. 2

The following are the kinds of it which I have met with:—

1. _Dragon's blood in the reed_; _Dragon's blood in sticks_; _Sanguis Draconis in baculis._—This occurs in dark reddish-brown sticks of from twelve to eighteen inches long, and from a quarter to half an inch in diameter, enveloped with the leaf of the Talipat palm (_Corypha umbraculifera_), and bound round with slender slips of cane (probably the stem of _Calamus petraeus_). It is supposed to be obtained from a species of _Calamus_, perhaps _C. Draco._

2. _Dragon's blood in oval masses_; _Dragon's blood in drops_; _Sanguis Draconis in lachrymis_, Martius.—This occurs in reddish-brown lumps of the size and shape of an olive, enveloped with the leaf of _Corypha umbraculifera_ or _Corypha Licala_, which thus connects them together in a row, like the beads of a necklace. This kind is rare in English commerce. It is obtained, according to Rumphius, by rubbing or shaking the fruit of _Calamus Draco_ in a bag. A resinous exudation is by this means separated, and is afterwards softened by heat, and made up in these masses.

3. _Dragon's blood in powder._—This is a reddish powder, of very fine quality, imported from the East Indies. It is probably the dust obtained from the fruit of the _C. Draco_, in the way just described.

4. _Dragon's blood in the tear_; _Sanguis Draconis in granis_, Martius.—It occurs in irregular pieces, some as large as the flat. T. W. C. Martius 3 says pieces of the fruit of the Calamus Rotang are frequently found intermixed.

5. _Lump Dragon's blood_; _Sanguis Draconis in massis._—This is of inferior quality. It occurs in large masses, which, when broken, present a heterogeneous appearance. Other varieties of _Dragon's blood_ are described, but I have never met with them. Guilbort mentions a _dragon's blood in cakes_, and a _false dragon's blood_ in oval masses.

_Dragon's blood_ is composed of red _resin_ (called _dramonin_) 90.7, _fixed oil_ 2.0, _benzene acid_ 3.0, _oxalate_ of _lime_ 1.6, _phosphate_ of _lime_ 3.7. 4 According to Johnstone, 5 the resin of _lump dragon's blood_ has the formula _C_9_H_20_O_4; that of _red dragon's blood_ _C_9_H_20_O_4.

---

1 The stems of this palm are sold at Haynes's timber-yard, Long Lane, Smithfield, London, under the name of Palm Wood.
2 De Candolle, May 16, 1835; also, Journal of Royal Geographical Society.
3 Pharmacognosia.
4 Herberger, _Journ. de Pharm._ xvi. 295.
It is inert, or nearly so, but was formerly reputed an astringent. It is a constituent of some tooth-powders and tinctures, but is never prescribed by medical practitioners. Its principal consumption is for colouring spirit and turpentine varnishes.

5. PALMÆ TANNINIFERÆ.—TANNIN-BEARING PALMS.

The only palm which yields any official astringent substance is the Areca Catechu.

54. ARECA CATECHU, Linn.—CATECHU PALM.

Sex. Syst. Monocæa, Hexandria.

(Semen.—Extract of the kernels, E.—Carbo seminis, Offic.)

HISTORY.—Areca nuts are not mentioned in the writings of the ancient Greeks and Romans. Avicenna speaks of them under the name of 

Sp. Char.—Trunk straight and slender, from forty to fifty feet high. Frons pinnate; leaflets compound, linear, opposite, premorse. Spathe erect, ramous. Male flowers hexandrous. Seed of a roundish conic form, and obtuse. (Roxburgh.)

Hab.—Cultivated in all the warmer parts of Asia.

1. DESCRIPTION AND USES OF THE SEEDS.—The fruit of the Catechu palm is about the size and shape of a small egg, yellowish, and smooth. Within the fibrous pericarp is the seed (areca nut; betel nut; pinang). This is about the size of a nutmeg, roundish conical, flattened at the base, hard, horny, inodorous, externally reddish brown, internally brown with whitish veins. The principal part of the seed is the ruminate albumen, at the base of which is the embryo.

The varieties of this fruit are numerous: of these, some have been figured by Blume, viz., Pinang Putie (Areca alba), Pinang Susu (Areca lactea), Pinang Betul (Areca propria), and Pinang Pict.

According to Morin, areca nuts (seeds) are composed of tannin (principally), gallic acid, glutin, red insoluble matter, fixed oil, gum, oxalate of lime, lignin, &c.

With lime and the leaves of Piper Betel, these nuts form the celebrated masticatory of the East, called betel. They are usually cut into four equal parts; one of which is rolled up with a little lime in the leaf of the Piper Betel, and the whole chewed. The mixture acts as a sialagogue, and tinges the saliva red. The Indians have an idea that by this means the teeth are fastened, the gums cleansed, and the mouth cooled. Peron was convinced that he preserved his health, during a long and difficult voyage, by the habitual use of the betel, while his companions, who did not use it, died mostly of dysentery. In this country, areca-nut charcoal is used as a tooth powder. I know of no particular value it can have over ordinary charcoal, except, perhaps, that derived from its greater hardness.

2. ARECA-NUT CATECHU.—In the southern parts of India, and probably in Ceylon, an extract called catechu is procured from areca nuts. The mode of preparing it has been described by Herbert de Jäger and Dr. Heyne. The last-
mentioned author states that it is largely procured in Mysore, about Sirah, in the following manner: "Areca nuts are taken as they come from the tree, and boiled for some hours in an iron vessel. They are then taken out, and the remaining water is inspissated by continued boiling. This process furnishes Kassu, or most astringent terra japonica, which is black, and mixed with paddy husks and other impurities. After the nuts are dried, they are put into a fresh quantity of water, boiled again, and this water being inspissated, like the former, yields the best or dearest kind of catechu, called Cowry. It is yellowish brown, has an earthy fracture, and is free from the admixture of foreign bodies."

None of the extracts brought from India under the denomination of catechu are distinguished by any name by which they can be referred to the areca nut. It is probable, however, that some of them which come over in the form of round and flat cakes, and also in balls, and which are more or less covered with paddy husks (glumes of rice), are obtained from this seed. A dejection of some of these kinds of catechu yields, when cold, a blue colour on the addition of iodine, indicating the presence of starch. The presence of fatty matter in them is considered by Professor Guibourt to be a proof that the areca nut has been employed in their production.

I think it probable that the Colombo or Ceylon catechu of commerce, in the form of round flat cakes, covered by paddy husks, is the Kassu of Heyne; and Professor Guibourt is of opinion that the dull reddish catechu in balls partially covered by paddy husks is the Cowry of Heyne. (For further details, the reader is referred to the article Acacia Catechu, where a general notice will be given of all the commercial sorts of catechu.)

†† Flowers with a true perianth free from the ovary (superior ovary), usually hermaphrodite.

**Order X. Melanthaceae, R. Brown.**

Characters.—Perianth inferior, petaloid, in six pieces, or, in consequence of the cohesion of the claws, tubular; the pieces generally involute in resurrection. Stamens six; anthers mostly turned outwards. Ovary three-celled; many seeded; style tridif or three-parted; stigma undivided. Capsule generally divisible into three pieces; sometimes with a loculicidal deliscence. Seeds with a membranous testa; albumen dense, fleshy. (R. Brown.)

Properties.—Several violently poisonous alkaloids (veratria, colchicina, tabadillina, and ferrina) are peculiar to this order. They exist in combination with organic acids. These bases, as well perhaps as resins, are the active principles of the order. The Melanthaceae are acrids (emetics, purgatives, diuretics, and errhines) and sedatives (see vol. i. p. 233). When acting as poisons, they are called narcotico-acrids (see vol. i. p. 234).

**55. Colchicum Autumnale, Linn.—Common Meadow Saffron.**

Sex. Synt. Hexandria, Trigynia.

(Herba agrata cornus recens et exsiccatus: semen. L.—Cormus et semina, E.—The cormus and seeds, D.)

History.—Dioscorides speaks of Colchicum (xoo*xio*), and states that it grows abundantly in Messenia and at Colchis (from which latter place it received its name). Dr. Sibthorps found three species of Colchicum in Greece—viz. C. autumnale, C. montanum, and C. variigatum; and of these he considers the first to be the Colchicum of Dioscorides. In this opinion he is to a certain extent confirmed by the editors of the Pharmacopoeia Graecae (1887), who apply the modern Greek name of xoo*xio* to C. autumnale. But there is reason to doubt the accuracy of this opinion: for this species is only found in Greece, on this side of the Spercheus, at an elevation of at least 3500 to 4000 feet—at Parnassus, and Thymphrastus; whereas

---

1 Journ. de Pharm. et de Chimie, 3me Sér. t. xi. p. 368, 1847.  
2 Prodr. Fl. Graec. l. 293.
C. variegatum, which Fraas\textsuperscript{1} thinks is the \textit{Xirobuni} of Dioscorides, is common, and occurs on the Xirobuni,\textsuperscript{2} at an elevation of only 1000 to 2000 feet, at Hymettus, Messapins, and Helicon.

For the introduction of colchicum into modern practice we are chiefly indebted to Störk,\textsuperscript{3} in 1763; but partly, also, to the opinion that it is the active principle of a celebrated French remedy (\textit{eau médicinale}) for gout.

**BOTANY.** **Gen. Char.**—Perianth single, tubular, very long, rising from a spatha; limb campanulate, six-partite, petaloid. [Stamens six, inserted into the throat of the tube. Ovarium three-celled. Styles three, filiform, long. Stigmas somewhat clavate.] Capsule three-celled; cells united at the base (Hooker, with some additions).

**Sp. Char.**—Leaves plane, broadly lanceolate, erect (Hooker).

Root fibrous. Cormus (improperly called root or bulb) ovate, fleshy, large, covered with a loose brown membrane. The leaves are produced in the spring along with the fruit, and disappear before the flower appears. Flowers several, lilac or pale purple, arising from the cormus by a long, narrow white tube.\textsuperscript{4} Fruit oblong, elliptical, composed of three cells, which may be regarded as distinct follicles, with intermediate fissures. Seeds small, spherical, with a rough brown testa and large fleshy strophiola; internally they are white, and consist of a minute embryo lodged in a horny elastic albumen. The flowers appear in September, and the fruit the following spring or summer.

There is a variety, \textit{\{florisbusreretinus\}} growing near Devizes, in Wiltshire, which flowers in the spring.

Florists cultivate several sorts; such as the white, the striped-flowered, the striped-leaved, the broad-leaved, the many-flowered, and the double flowered.

**Hab.**—Moist rich meadows in many parts of England and in various countries of Europe. The plant is propagated by seeds, by a single mature cormus, or by several immature or infant cormi.

**Collection of the Cormi.**—The cormus is biennial. It first appears about the end of June or beginning of July: it flowers in the autumn, and produces its leaves in the spring, and its seed in the June of the following year. It then begins to shrivel, becomes leathery, and finally disappears in the succeeding spring or summer.

The activity of the cormus varies at different seasons of the year. It is usually considered to be greatest when the cormus is about a year old—that is, about the month of July, between the withering of the leaves and the sprouting forth of the flower of the young cormus. At this period the cormus is fully developed, and has not exhausted itself by the production of the young one. But many of the cormi brought to market have already pushed forth their flowers, which are broken off so as to prevent the

---

\textsuperscript{1} *Synopsis Plant. Flora Classicæ*, p. 281, 1845.

\textsuperscript{3} *Libellus quo demonstratur Colchici Autunnalis Radicem non solum tuto posse exhiberi hominibus, sed et ejus usu interno curari quandoque morbos difficilimos, qui alius Remedii non cedent*, erro. Vindob. 1763.

\textsuperscript{4} Miller says that, in Warwickshire, the flowers are called naked ladies, because they appear without leaves.
circumstance from being observed. "I have seen many cwtws," says Dr. Lindley,1 "sent to town in this state, which nevertheless found a ready sale, and at the best price."

It is to be dug up in the month of July, or before the autumnal bud shoots up.—Ph. Lond.

Dr. Christison2 has expressed some doubts as to the propriety of collecting the cormi in July; for though they are plumpest, firmest, and abound most in starch at this period, yet he has found the shrivelled cormi in the succeeding April to be equally if not more bitter; and he quotes the analyses of Stoltze to show that, while the October cormus yields 2 per cent., the March cormus yields 6 per cent., of bitter extract. But there is an error in the quotation which vitiates the inference intended to be drawn from it. Stoltze found that the October cormus contained 2.17 per cent. of bitter extractive, and that the March cormus contained 5.91 of sweet extractive matter combined with some bitter extractive; and he concludes that the October cormus is much more active, and contains more bitter extractive, than the spring cormus.

The seeds should be gathered when fully ripe. The London market is principally supplied from Gloucestershire, but partly, also, from Hampshire and Oxfordshire.

Description.—The cormus, commonly called the bulb or root (radix colchici, Offic.), when gathered at the proper season, is about the size of a chestnut, and somewhat resembles in external appearance the bulb of the common tulip (Tulipa Gesneriana); which, as well as other liliaceous bulbs, are distinguished from the cormus of colchicum by being composed of laminae or scales, whereas the cormus of colchicum is solid.3 It is rounded on one side—flattened on the other, where is perceived the fibrous germ of a new cormus, which, if allowed to grow, shoots up and bears the flower, while the old cormus wastes. It is covered by two coats—an inner reddish-yellow one, and an external brown one. Internally, the cormus is white, fleshy, solid; contains a milky juice, is very feculent, and has an acrid bitter taste.

Description.—The slices are to be quickly dried, in a dark airy place, with a heat not exceeding 170° F.4

Having removed the outer coats, cut the cormus transversely in thin slices, and dry by a heat which is to be at first gentle, and afterwards slowly raised to 150°.—Ph. Lond.

The late Dr. A. T. Thomson5 recommended the slices to be dried upon clean white paper without artificial heat; but the time required for this is an objection to it in practice. The dried slices (radix siccata, Offic.) should be about the eighth or tenth of an inch thick, rounded, oval, with one notch only on one part of their circumference (not fiddle-shaped), inodorous, of a grayish-white colour and an amylaceous appearance.

The seeds (seminia) are about the size of those of black mustard, odourless, and have a bitter acrid taste. Their colour is brown, varying from pale to dark or blackish. They somewhat resemble several of the cruciferous seeds (black mustard, turnip, and rape), but are larger than these; moreover, the latter being more oily are more readily crushed. I have known colchicum seeds mistaken for grains of paradise.

Composition.—The colchicum cormus was analyzed in 1810 by Melander, and Moretti;6 in 1818 and 1819, by Stoltze;7 and in 1820 by Pelletier and Caventon.8

The seeds have been submitted to chemical examination, in 1832, by L. A. Buchner, Jun.,¹ who found in them fixed oil, free acid, bitter extractive (impure colchicina), and resin.

1. **Colchicina; Colchica; Colchicene.—** The existence of this principle in colchicum seeds was announced by Geiger and Hesse.² They prepared it by digesting the seeds in boiling alcohol: this dissolved a supersalt, which was precipitated by magnesia, and the precipitate treated with boiling alcohol. By evaporation, colchicina was deposited. The following are said to be its properties: It is a crystallizable alkaline substance, without colour, but having a bitter taste. Its hydrate is feebly alkaline, but neutralizes acids, and forms crystallizable salts having a bitter taste. It is soluble in water, and the solution precipitates the solution of chloride of platinum. Nitric acid colours colchicina deep violet, which passes into indigo blue, and quickly becomes first green and then yellow. Concentrated sulphuric acid colours it yellowish brown.

Colchicina is said to be distinguished from veratrum by the following characteristics: 1st, it is soluble in water, whereas veratrin is not; 2dly, it is crystallizable, whereas pure veratrin is not; 3dly, it does not possess the acidity of veratrin; and it differs from the latter in this, that, when applied to the nose, it does not excite sneezing, whereas the least portion of [impure] veratrin occasions a most convulsive sneezing.

Colchicina is a powerful poison. One tenth of a grain, dissolved in weak spirit, killed a young cat in about twelve hours. The symptoms were salivation, diarrhœa, vomiting, a staggering gait, cramps, convulsions, and death. The stomach and intestines were violently inflamed, and had extravasated blood throughout the whole course.

2. **Starch.**—The starch grains of the cormus of colchicum are moderately uniform in size; though normally rounded, they present more or less flattened faces, produced by their mutual compression in the cells of the plant, by which they have acquired a polygonal appearance. Many are mullar-shaped, some are dillhedral at one end, others trididral; owing to the mutual pressure of two, three, or four particles. The hilum is usually stellate.

**Chemical Characteristics. a. Of the Cormi.**—The decoction of the fresh cormi, when cold, forms, with a solution of iodine, a deep blue precipitate (iodide of starch); with sesquichloride of iron, a faint bluish tint (gallate of iron); with diacetate of lead, or protonitrate of mercury, a copious white precipitate; with nitrate of silver, a precipitate which is at first white, but becomes in a few minutes black; with tincture of nutgalls, a very slight, dirty-looking precipitate, which is somewhat diminished by the effect of heat [Pelletier and Caventou³ regard this precipitate as a mixture of the tannates of starch and inulin (and of veratrin?)]; and with a solution of gelatine, a slight haziness. Fresh-prepared tincture of guaiacum, with a few drops of acetic acid, produces a cerulean blue colour with the fresh cormus, indicating the presence of gluten.

β. Of the Seeds.—The decoction of the seeds, when cold, yields, with oxalate of ammonia, a white precipitate (oxalate of lime); with diacetate of lead, a copious white precipitate; and, with nitrate of silver, a precipitate. If the decoction be concentrated, and poured into alcohol, a gelatiniform precipitate is produced.

**Physiological Effects. a. On Vegetables.**—Not yet determined.

β. On Animals.—Colchicum is a poison to animals. It acts as a local irritant,

¹ Report. für die Pharm. Bd. xiii. S. 376, 1832.
³ The precipitate produced in an amylaceous decoction by infusion of nutgalls, disappears when the liquor is gradually heated to 192° F.; but if inulin be present, it does not disappear until the liquor has reached the boiling point.
reduces the force of the circulation, and causes inflammation of the alimentary canal. Animals, for the most part, refuse to feed on it. It has, however, been eaten by deer and cattle, and proved poisonous to them. It is said to prove injurious at spring-time only. Moreover, we are told that when dry it may be eaten in hay with impunity. Störek and Kratochwill gave it to dogs, on whom it acted as an acrid poison, and caused death. Sir E. Home injected 160 drops of a vinous infusion of colchicum into the jugular vein of a dog: all power of motion was instantly lost, the breathing became slow, the pulse hardly to be felt. In ten minutes it was 84, in twenty minutes 60, in an hour 115, with the respiration so quick as scarcely to be counted. In two hours the pulse was 150, and very weak. The animal was purged, vomited, and very languid: he died in five hours. On dissection, the internal coat of the stomach was found inflamed, in a greater or less degree, universally. From this experiment it appears that the action of colchicum on the alimentary canal is of a specific kind.

In opposition to the above statements, it deserves notice that Orfila has frequently given to dogs, in the month of June, two or three corns without perceiving any sensible effects; from which he infers that climate and season of the year have great influence on their deleterious properties.

It has been said that horses eat colchicum with impunity; but it is probable that this statement is erroneous. Withering states, on the authority of Mr. Woodward, that, "in a pasture in which were several horses, and eaten down nearly bare, the grass was closely cropped, even under the leaves, but not a leaf bitten."

Some further information on the effects of colchicum on dogs will be found in Sir C. Seudamore's Treatise on Gout and Rheumatism, 3d edit. p. 477, 1819.

γ. On Man.—Colchicum is acrid and sedative. Taken internally, in small and repeated doses, it promotes the action of the secreting organs, especially the intestinal mucous membrane. The kidneys, the skin, and the liver, are less certainly and obviously affected by it. Salivation has been ascribed to it by Dr. Aldridge. The most constant effects observed from the use of larger doses are nausea, vomiting, and purging. Reduction of the frequency of the pulse is a common, though not an invariable effect. Mr. Haden was, I believe, the first to direct attention to the advantages to be taken of this effect in the treatment of inflammatory diseases. In some experiments made on healthy individuals by Dr. Lewins, debility, a feeling of illness, and headache, were experienced. This feeling of debility is not, however, to be referred to the evacuations produced; for, as Dr. Barlow has observed, the number of motions is sometimes considerable without any proportionate depression of strength ensuing. "I have known," says Dr. B., "even twenty stools occasioned by a single dose of colchicum, the patient not complaining of the least debility."
The action of colchicum on the secretory apparatus is not confined to that of the alimentary canal: after the use of three or four full doses of this medicine, copious sweating is often produced, especially when the skin is kept warm. On other occasions, the kidneys are powerfully acted on. In one case, mentioned by Dr. Lewins, seventy drops of Vinum Colchici caused the discharge of upwards of a pint of bile by vomiting. Violent salivation resulted, in a case recorded in an American journal. Chelius, of Heidelberg, asserts that, in gout and rheumatism, colchicum occasions a striking increase in the quantity of uric acid contained in the urine: in one case it was nearly doubled in the space of twelve days. But this effect is by no means constant, as Dr. Graves has pointed out. Indeed, it some-

times happens, in acute rheumatism, when the urine is loaded with uric acid or the urates, that under the use of colchicum the quantity of these matters in the urine is diminished; so that it would seem rather to prevent the formation of uric acid in the system than to provoke its elimination.

In excessive or poisonous doses colchicum acts as a powerful poison. In a case related by Mr. Fereday, where two ounces of the wine of the seeds of colchicum were swallowed, the symptoms were acute pain in the bowels, coming on in about an hour and a half after taking it; vomiting; acute tenesmus, small, slow, and feeble pulse, cold feet, and weakness of limbs. The nausea, vomiting, and pain in the stomach continued with undiminished violence, the pulse became also imperceptible and intermitting, the urine was suppressed, the respiration hurried, purging of copious liquid stools came on, and loss of sight for a minute or two after getting out of bed. The patient died forty-seven hours after swallowing the poison. On a post-mortem examination, the skin of most parts of the body was found to be covered with a purple efflorescence: no inflammation was observed in the alimentary canal; two red patches were found, one in the stomach, and the other in the jejunum. These were produced by the effusion of a small quantity of blood, in the one case, between the muscular and mucous coats; in the other, between the peritoneal and muscular coats. Ecchymosed spots were observed on the surface of the lungs, of the heart, and of the diaphragm. More recently, a case of poisoning by a decoction of the seeds has been recorded; as, also, by the leaves of this plant.

In Mr. Fereday’s case, the only indications of an affection of the nervous system were weakness of the limbs, the temporary loss of sight, and the slowness and feebleness of the pulse.

It is deserving of notice that, in this case, also in another related by Chevallier, likewise in a third mentioned by Mr. Dillon, and in Mr. Haden’s case, no convulsions were observed; and, in the first three cases, no insensibility. In the last case, however, Mr. Haden mentions that at ‘‘ten P. M. she fell into an apoplectic kind of sleep, which terminated in death before morning.’’ It is remarkable that convulsions are ascribed to veratrina by Magendie, and to colchicina by Geiger and Hesse. In one case of fatal poisoning from an ounce and a half of the tincture of colchicum, delirium occurred.

It is a popular notion that colchicum acts as an emmenagogue; and hence it is sometimes used to produce abortion. Several poisonous cases of its use for this purpose have occurred.

Some persons appear to be peculiarly susceptible of the influence of colchicum. In Mr. Haden’s case, 3ijss of tincture of colchicum caused death in a female whose mother was also exceedingly susceptible of the action of colchicum in even very small doses. In a case related by Mr. Mann, 3ijss of the wine of colchicum in divided doses caused death on the fourth day.

The above account of the effects of colchicum applies both to the cormi, the seeds, and the leaves. The flowers are likewise poisonous, and a fatal case from their use is mentioned by Dr. Christison. They have been recommended for medicinal use.

Uses.—The following are the principal diseases in which the Meadow Saffron has been employed:—

1. In Gout.—The circumstances which of late years have led to the extensive employment of colchicum in gout are the following: About seventy years ago, M. Husson, a military officer in the service of the king of France, discovered, as he informs us, a plant possessed of extraordinary virtues in the cure of various diseases. From this plant he prepared a remedy called Eau Médicinale, which acquired great celebrity for abating the pain and cutting short the paroxysm of

7 Taylor, On Poisons.
8 Treatise on Poisons, 3d ed. p. 792.
gout. Various attempts were made to discover the nature of its active principle. In 1782, MM. Cadet and Parmentier declared that it contained no metallic or mineral substance, and that it was a vinous infusion of some bitter plant or plants. Alyon a asserted that it was prepared with Gratiola; Mr. Moore b that it was a vinous infusion of white hellebore with laudanum; Mr. Want c that it was a vinous infusion of colchicum. Although most writers have adopted Mr. Want's opinion, we should bear in mind that the proofs hitherto offered of its correctness, viz., analogy of effect, cannot be admitted to be conclusive, as is well shown by the fact that they have been advanced in favour of the identity of other medicines with the Eau Médicinale.

The power of colchicum to alleviate a paroxysm of gout is admitted by all; but considerable difference of opinion exists as to the extent of this power, and the propriety of employing it. Sir Everard Home, d from observation of its effects on his own person, regarded it as a specific in gout, and from experiments on animals concluded that its beneficial effects in this malady are produced through the circulation.

Dr. Paris e observes: "As a specific in gout its efficacy has been fully ascertained; it allays pain, and cuts short the paroxysm. It has also a decided action upon the arterial system, which it would appear to control through the medium of the nerves." But if by the word specific is meant a medicine infallibly, and on all patients, producing given salutary effects, and acting by some unknown power on the disease, without being directed by indications, f undoubtedly colchicum is no specific for gout.

That colchicum alleviates a paroxysm of gout, I have before mentioned; but that alleviation is palliative, not curative. It has no tendency to prevent a speedy recurrence of the attack; nay, according to Sir Charles Sendamoro, g it renders the disposition to the disease much stronger in the system. Furthermore, by repetition its power over gouty paroxysms becomes diminished.

The modus medendi of colchicum in gout is an interesting, though not very satisfactory part of our inquiry. I have already stated that some regard this remedy as a specific; that is, as operating by some unknown influence. Others, however, and with more propriety, refer its therapeutical uses to its known physiological effects. "Colchicum," says Dr. Barlow, h "purges, abates pain, and lowers the pulse. These effects are accounted for by assigning to it a cathartic and sedative operation; and it is this combination, perhaps, to which its peculiar virtues are to be ascribed." The fact that a combination of a drastic and a narcotic (as elaterium and opium, mentioned by Dr. Sutton, i and white hellebore and laudanum, recommended by Mr. Moore) j has been found to give, in several cases of gout, marked and speedy relief, seems to me to confirm Dr. Barlow's opinion. The idea entertained by Chelius, and adopted by Dr. G. Hume Weatherhead, k that colchicum relieves gout by augmenting the quantity of uric acid in the urine, is not supported by fact, as I have already mentioned. Whether it acts by preventing the formation of uric acid in the system, I am not prepared to say.

In acute gout occurring in plethoric habits, blood-letting should precede the use of colchicum. This medicine should then be exhibited in full doses, so as to produce a copious evacuation by the bowels, and then the quantity must be considerably diminished. Though purging is not essential to the therapeutic influence of colchicum, it is admitted by most that, in a large number of cases at least, it promotes the alleviation of the symptoms. Hence, many practitioners recommend its com-

VOL. II.—12
bination with saline purgatives, as the sulphate of magnesia. Sir Charles Seudamore has experienced "the most remarkable success from a draught composed of Magnesia gr. xy ad xx; Magnes. Sulphat. 3ij ad 5ij; Aceti Colchici 3ij ad 5ij; with any distilled water the most agreeable, and sweetened with any pleasant syrup, or with 15 or 20 grains of Extract. Glycyrrhiza."

2. In rheumatism.—The analogy existing between gout and rheumatism has led to the trial of the same remedies in both diseases. But its therapeutical powers in the latter disease are much less marked than in the former. Rheumatism may affect the fibrous tissues of the joints, the synovial membrane, the muscles or their aponerotic coverings, the periosteum, or the neurilemma, constituting thus five forms of the disease, which may be denominated respectively the fibrous or ligamentous; the synovial, arthritic, or capsular; the muscular; the periosteal; and the neuralic forms of rheumatism. Of these, colchicum is said to produce its best effects in the synovial form. It is remarkable, however, that in all the severe cases of this variety of rheumatism which have fallen under my notice, the disease has proceeded unchecked, or was scarcely relieved by the use of colchicum. In one instance, that of my much-lamented friend, the late Dr. Cummin (whose case is noticed by Dr. Macleod, in the Lond. Med. Gaz. xxii. 358), the disease proved fatal by metastasis to the brain. In another melancholy, but not fatal case, the gentleman lost the sight of both his eyes, and has both knee-joints rendered stiff. In neither of these cases was colchicum of the slightest avail.

Of the mode of administering colchicum in "rheumatic gout," recommended by Mr. Wigan, I have no experience. He gives eight grains of the powder in some mild diluent every hour until active vomiting, profuse purging, or abundant perspiration take place; or, at least, till the stomach can bear no more. The usual quantity is eight or ten doses; but, while some take fourteen, others can bear only five. Though the pain ceases, the more active effects of the colchicum do not take place for some hours after the last dose. Thus administered, Mr. Wigan declares colchicum "the most easily managed, the most universally applicable, the safest, and the most certain specific in the whole compass of our opulent Pharmacopoeia." But its use in these large doses requires to be carefully watched.

3. In dropsy.—Colchicum was used in dropsy with success by Stöck. It has been employed in dropsical cases with the twofold view of purging and promoting the action of the kidneys. Given in combination with saline purgatives, I have found it beneficial in some cases of anasarca of old persons.

4. In inflammatory diseases generally.—Colchicum was recommended as a sedative in inflammatory diseases in general by the late Mr. C. T. Haden. He used it as an auxiliary to blood-letting, for the purpose of controlling arterial action; and gave it in the form of powder, in doses of six or seven grains, three or four times daily, in combination with purgatives, in inflammatory affections of the lungs and their membranes, and of the breasts and nipples. In chronic bronchitis it has also been found useful by Dr. Hastings.

5. In fevers.—The late Mr. Haden, and more recently Dr. Lewin, have spoken favourably of the use of colchicum in fever. In my opinion, it is only admissible in those forms of the disease requiring an active antiphlogistic treatment. In such it may be useful as an auxiliary to blood-letting and cathartics.

6. In various other diseases.—For expelling tape-worm, colchicum has been found efficacious by Chisholm and Baumbach. In some chronic affections of the nervous system, as chorea, hypochondriasis, hysteria, &c., Mr. Raven employed it with advantage. In humoral asthma, and other chronic bronchial affections, I have

---

6 London Medical and Physical Journal, Jan. 1817.
found it of great service, especially when these complaints were accompanied with anasaric swellings.

Administration.—The cormi and seeds of meadow saffron have been employed in substance, in a liquid form, and in the state of extract.

1. PULVIS CORMI COLCHICI.—Dose, from two to eight or nine grains. To preserve it, Mr. Wigan recommends it to be kept mixed with sugar.

2. PULVIS SEMINUM COLCHICI.—Dose the same as that of the cormus. The seeds are to be preferred to the cormi, as being more uniform in their properties.

3. TINCTURA [SEMINUM] COLCHICI, L. Ed.; Tinctura Seminum Colchici, D. [Tinctura Seminis, U. S.].—(Meadow Saffron seeds, bruised [ground finely in a coffee-mill, Ed.], 3v; Proof Spirit Oij. Macerate for seven [fourteen, D.] days, and strain, L. "Percolation is much more convenient and speedy than digestion," E.—[Colchicum seed, bruised, four ounces; diluted alcohol two pints. Macerate for fourteen days, express and filter through paper, or moisten the powder with the diluted alcohol, allow to stand for twenty-four hours, and then displace, U. S.].—Dr. Williams objected to this preparation as being "turbid, unpalatable, and disposed to precipitation." The same writer also asserts that the active property of the seeds resides in their husk or cortical part, and, therefore, protests against bruising them. But were his assertion correct (and it is most improbable that the embryo is devoid of activity), bruising them cannot destroy or injure their activity. The average dose is from $\frac{1}{2}$s to $\frac{1}{2}$j. I have repeatedly given $\frac{1}{2}$j at a dose without any violent effect. Dr. Barlow, who prefers this to the other preparations of colchicum, advises that in gout a drachm, in a drachm and a half, or two drachms of the tincture should be given at night, and repeated the following morning. If this quantity fail to purge briskly, a third dose may be administered the ensuing night. Externally, the tincture has been employed as a liniment to relieve rheumatic, gouty, venereal, and other pains.

4. TINCTURA [SEMINUM] COLCHICI COMPOSITA, L.; Spiritus Colchici ammoniatus, L. 1824.—(Meadow Saffron seeds, bruised, 3v; Aromatic Spirit of Ammonia Oij. Macerate for seven days, then express and strain.) Dose $\frac{1}{2}$xx to $\frac{1}{2}$j.—This preparation was recommended by Dr. Williams as being "of greater value when acidity or flatulence prevails than the Vin. sem. Colchici, and better adapted to the palates of those who object to the flavour of white wine." It is seldom employed. Mr. Brande says doubts are entertained as to the propriety of employing ammonia in it.

5. VINUM SEMINUM COLCHICI [Vinum Colchici Seminis, U. S.].—No formula for this exists in any of the British pharmacopoeias. The following is Dr. Williams's formula: Meadow Saffron seeds, dried, $\frac{1}{2}$jj; Sherry Wine Oij [wine measure]. Macerate for eight or ten [fourteen] days, occasionally agitating, then filter. The average dose is $\frac{1}{2}$ss to $\frac{1}{2}$j. I have given it to the extent of $\frac{1}{2}$jj. Dr. Williams says it may be gradually increased to $\frac{1}{2}$jj.

This formula has been adopted by the U. S. Pharmacopoeia, which directs double the proportion of each of the ingredients, and directs maceration for fourteen days.

6. VINUM [CORMI] COLCHICI, L. E. [Vinum Colchici Radicis, U. S.].—(Meadow Saffron cormus, dried and sliced, $\frac{1}{2}$viiij; Sherry Wine Oij. Macerate for seven days [express strongly the residuum, E.], and strain.) [The directions of the U. S. Pharm. are: Take of Colchicum Root one pound; White Wine two pints. Macerate for fourteen days, with occasional agitation, and filter; or by displacement.] Average dose $\frac{1}{2}$ss to $\frac{1}{2}$j.—Sir E. Home thought that the second and subsequent deposits

---

which take place from this wine contain the principle which acts on the stomach and bowels, while that which cures the gout is retained in permanent solution. But Sir C. Seudamore\(^1\) found the sediment to be inert.

7. **ACETUM [CORMI] COLCHICI**, L. E. D. [U. S.].—(Meadow Saffron cormus, dried [and bruised, \(D\)], \(§\)vi\(\text{s}\) \(\|\) D]; Dilute Acetic Acid Qj [Acetic Acid of commerce (sp. gr. 19\(\frac{4}{10}\)) \(\|\) vi; Distilled Water \(\|\) \(\text{vi}\), \(D\)]; [Proof Spirit \(\|\) vi\(\text{s}\), \(L\)]. Macerate the colchicum in the acid [diluted with the water, \(D\)], in a covered vessel, for three [seven, \(D\)] days; then express, set aside for the feces to subside, and strain. [To the strained liquor, add the spirit, \(L\).]—The Edinburgh College directs colchicum-bulb, fresh and sliced, \(\|\); Distilled Vinegar \(\|\).—The London and Dublin Colleges, in their Pharmacopoeias for 1850, have very properly substituted the dried for the fresh cormus ordered in the preceding Pharmacopoeia, on account of the impossibility of procuring the fresh at all seasons of the year. [The \(U. S. Pharm.\) orders of Colchicum Root, bruised, two ounces; Diluted Acetic Acid two pints. Macerate the root with the diluted acetic acid, in a close glass vessel, for seven days; then express the liquor and set it by, that the dregs may subside; lastly, pour off the clear liquor.\(^2\)]—In practice, one part of the dried cormus may be considered equal to three parts of the fresh: for Mr. Battley\(^3\) says the cormus loses about 67 per cent. of its weight in drying; and Mr. Bainbrigge\(^4\) obtained 2 lbs. 15 oz. of dried slices from 8 lbs. of fresh cormi. The proof spirit used in preparing the acetum is for the purpose of checking decomposition. By the action of the acetic acid on the colchicina of the cormus, an acetate of this alkaloid is obtained. Sir C. Seudamore\(^5\) regards an acetic preparation of colchicum as milder than the wine or tincture made with the same relative weights of cormi and liquids, though it is a most efficient preparation in gout. He advises, as I have before mentioned, that it should be given in combination with magnesia, by which its acid menstruum is destroyed (acetate of magnesia being formed), and the active principle of the colchicum left in the most favourable state for administration. The average dose is from \(\|\) to \(\|\).

8. **EXTRACTUM [CORMI] COLCHICI ACETICUM**, L. E. D. [U. S.].—(Fresh Meadow Saffron cormus, ibj; Acetic [pyroligneous, \(Ed.\)] Acid \(\|\) iiij. Bruise the cormus gradually sprinkled with the acetic acid, then press out the juice, and evaporate it in an earthen vessel which is not glazed with lead [over the vapour-bath, \(Ed.\)] to a proper consistence. The Dublin College orders of Colchicum Root, dried, \(\|\); Dilute Acetic Acid \(\|\). Digest the root in the acid for fourteen days, then filter, and evaporate, by means of a water-bath, to the consistence of a soft extract. [Take of Colchicum Root, in coarse powder, a pound; Acetic Acid four fluid-ounces; Water a sufficient quantity. To the acetic acid add a pint of water, and mix the resulting liquid with the colchicum root. Transfer the mixture to a percolator, and pour water gradually upon it until the liquid passes with little or no taste. Lastly, evaporate the liquid in a porcelain vessel to the proper consistence, \(U. S.\).]—This compound contains the acetate of colchicina. It is a very favourite remedy in the treatment of gout and rheumatism, and was introduced into practice by Sir C. Seudamore. Dr. Paris\(^6\) observes that he has "found it useful in promoting healthy discharges of bile." He occasionally combines it with blue pill, calomel, or potassio-tartrate of antimony. The dose is from gr. j to gr. iiij twice or thrice a day.

9. **EXTRACTUM COLCHICI [CORMI]**, L.—(Fresh Meadow Saffron cormus ibj. Bruise the cormus, sprinkled with a little water, in a stone mortar; then press out the juice, and evaporate it, unstrained, to a proper consistence.)—This is a favourite

---

5. *Appendix to the Eighth Edition of the Pharmacologia*.
10. **Succes Colchici; Preserved Juice of Colchicum.**—I am informed that in one experiment from one cwt. of very fine cormi gathered at the end of August, and well bruised and pressed, four imperial gallons and 5 xij of a light fawn-coloured juice were obtained. This juice becomes darker coloured by exposure to the air. After standing forty-eight hours the spirit is added to it. A large quantity of feculent deposit is formed, and the liquor acquires a paler tint. The deposit by boiling yields a coagulum. Exposure to light appears to render it somewhat paler. The smallest dose of succes colchici is five minims.

**Antidote.**—See **Veratrum album.**

56. **Hermodactylus, Auct.—Hermodactyl.**

**History.**—Among the later Greek and the Arabian physicians, a medicine called hermodactyl (ηρομδακτυλα, from ηρομδακτυλα, Mercury or Hermes; and δακτυλος, a finger) was in great repute as a remedy for arthritic diseases. It was first mentioned by Alexander of Tralles, who flourished A.D. 569. Paulus Eugenius, who lived A.D. 650, Aucmena, Serapion, and Mesue, also speak of it. It is deserving of especial notice, that, under the name of Saurum or Hermodactyl, Serapion comprehends the κολχικος and τηφιμορος of Dioscorides, and the ιμπολικος: of Paulus. By some of the old writers, hermodactyl was called anima articulorum, or the soul of the joints.

**Natural History.**—The cormi brought from Oriental countries in modern times under the name of hermodactyl, answer to the descriptions given of the ancient substance bearing this name. I am, therefore, induced to believe them to be identical with the latter. Their resemblance to the cormi of Colchicum autumnale leads me to reject the notion of Matthiolus, at one time entertained by Linnaeus, and adopted by Martius and Frans, that they are produced by *Iris tuberosa*. That they are the underground stems of some species of colchicum can scarcely, I think, be doubted by any one who carefully examines them. Notwithstanding the statements of Mr. Want and of Sir H. Halford, I cannot admit the assumption that hermodactyls are the cormi of *Colchicum autumnale*, though this is the only species of *Colchicum* admitted into the new Greek Pharmacopoeia. Though resembling the latter in several circumstances, they possess certain distinct peculiarities. Some of the most eminent pharmacologists of Europe (e.g. Guibourt, Goebel, Geiger, Geoffroy, &c) also regard them as distinct. The *Colchicum illyricum*, mentioned in many works as yielding hermodactyl, is unknown to modern botanists. The cormus of *Colchicum byzantinum* is too large to be confounded with hermodactyl. *Colchicum variegatum* has been supposed by several botanists and pharmacologists to be the source of hermodactyl, but further evidence is required to establish the opinion. This plant is a native of Sicily, Crete, Greece, and Portugal. Dr. Sibthorp found it on Helicon, Parnassus, and other mountains of Greece. It is not improbable, I think, that *Colchicum bulbocodiodes* may yield hermodactyl, which Dale tells us is brought from Syria. Dr. Lindley informs me that this species was found by Colonel Chesney near the Euphrates, where it was very common, flowering in March. The cormi were not brought over. *Iris tuberosa* was not found there. Forskål found *Colchicum montanum* (which Sprengel, in his *Syst. Veg.*, regards as identical with *C. bulbocodiodes*) at Kurma, in Arabia.

**Description.**—Mesue says that hermodactyl is either long, like the finger, or round. Of the round, he adds, there are three kinds—the white, the red, and the black; the white being the best. C. Baulin considered that the black and red hermodactyl of Mesue and Serapion are *C. autunnale*, or, as he terms it, "Colchicum commune;" but the white hermodactyl he regarded as a distinct kind, which he calls "Colchicum radice sicenta alba." Through the kindness of my friend Professor Royse, I have had the examination of two kinds of hermodactyl, procured by him in the bazaars of Northern India, brought, he thinks, from Surat or Bombay, and probably imported there from the Red Sea.

1. **Tasteless Hermodactyl; Sorinjan sheoram (i.e. sweet sorinjan), Royse; Hermodactylus, Auct. nostrum usitatissimum.**—In their general form these cormi resemble those of *Colchicum autumnale*. They are flattened, cordate, hollowed out or grooved on one side, convex on the other. At

their lower part (forming the base of the heart) is a mark or disk for the insertion of the root fibres. Their size varies: the specimens I have examined were from \( \frac{3}{2} \) to 1 1/2 inches in length or height, 1 to 1 1/2 inches in breadth, and about \( \frac{3}{2} \) an inch in depth. They have been deprived of their coats, are externally dirty yellow or brownish, internally white, easily broken, farinaceous, opaque, odourless, tasteless, or nearly so, and worm-eaten. They agree precisely with herbodactyl furnished me by Professor Guibourt. They are readily distinguished from the cormi of Colchicum autumnale by the following characters, which are correctly stated by Geoffroy. They are not rugose, are white internally, are moderately hard, easily broken, and form a whitish powder; whereas the dried cormi of Colchicum autumnale are rugose, softer, and have a reddish or grayish tint both internally and externally.

2. Bitter Herbodactyl; Sorinjan tulch (i.e. bitter sorinjan), Royle. Bulb [cormi] of another Colchicum.2 ?? Herbodactylus rubens et nigrier (Avicenna and Messeu).—The cormi of this variety are distinguished from the preceding by their bitter taste, their smaller size, and by having externally a striped or reticulated appearance. Their colour for the most part is darker; in some specimens it is blackish. One cormus is ovate-cordate; 1 inch in height or length, \( \frac{3}{2} \) of an inch broad, and about \( \frac{4}{5} \) of an inch thick, grooved or hollowed on one side, convex on the other; of a brownish-yellow colour, semi-transparent, has a horny appearance, and is marked by longitudinal stripes, indicating a laminated structure. A second is opaque, amylaceous, reticulated externally, white internally, less flattened, and of a remarkable shape, the concave or hollow side of the cormus being continued half an inch below the mark for the attachment of the root. The other cormi are of the size and shape of a large orange pip, but flattened or grooved on one side; some of them are worm-eaten, and one is blackish-brown externally.

**Composition.**—Lecanu3 analyzed herbodactyls (the tasteless variety), and obtained the following results: Starch (forming the principal constituent of the herbodactyl), fatty matter, yellow colouring matter, gum, supernatals of lime and potash, and chloride of potassium.

Is the absence of veratria or colchicina to be ascribed to the cormi having undergone decomposition by keeping? No inulin was detected.

**Chemical Characteristics.**—Both the tasteless and bitter herbodactyls are blackened by tincture of iodine, showing the presence of starch. A cold decoction of the bitter variety produced an intense blue precipitate (iodide of starch) with a solution of iodine. Tincture of galls, and solutions of protomitate of mercury, and of diacetate of lead, caused a cloudiness in the cold decoction.

**Effects and Uses.**—No modern experiments have been made to determine the activity of herbodactyls. The tasteless variety is probably inert, or nearly so; but the bitter variety, I suspect, possesses some activity. Is its operation analogous to that of the cormus of Colchicum autumnale?

Speaking of the treatment of gout and arthritis, Paulus says: "Some, in the paroxysms of all arthritic diseases, have recourse to purging with herbodactyls; but it is to be remarked that the herbodactyl is bad for the stomach, producing nausea and anorexia, and ought, therefore, to be used only in the case of those who are pressed by urgent business, for it removes rheumatism speedily, and after two days at most, so that they are enabled to resume their accustomed employment."4

57. VERATRUM ALBUM, Linn. —WHITE HELLEBORE.

**Sex. Syst.** Polygamia, Monoeica.

(Rhizoma, L.—Rhizoma, E.)

**History.**—This is, I think, the \( \xi \xi \chi \beta \varepsilon \sigma \omega \varepsilon \varsigma \varepsilon \zeta \varsigma \varsigma \zeta \) of Dioscorides (lib. iv. cap. 150), and probably, therefore, of other ancient writers, as Hippocrates and Theophrastus. On this point, however, considerable difference of opinion has existed. Schulze,5 while he acknowledges the great similitude between Veratrum album, Linn. and the white hellebore of Dioscorides, is of opinion that the true hellebore (both white and black) of Theophrastus is wholly lost. And Dr. Sibthorp,6 who found both *V. album* and *V. nigrum* in Greece,7 regards *Digitalis ferruginea* as the white hellebore of Dioscorides—an opinion from which Sir J. Smith, the editor of the Prodromus, expresses his dissent.8 The term *veratum* is said by Lemery to be derived from

6 Neither Fuss, nor any other botanists, whose collections in Greece he examined, found either of the above-mentioned species of veratum.
7 For some interesting information respecting the ancient hellebore, consult Dierbach, Arzneimittel. d. Hippocrates, p. 167.
from *vera atrum* (truly black), in reference to the colour of the rhizome; but this etymology is improbable.

**Botany.** — **Gen. Char.** — Flowers polygamous. *Perianth* six-parted; segments broad, concave, imbricating, nearly equal, striated, not excavated at the base. *Stamens* six, equal, inserted into the base of the segments; *filaments* subulate; *anthers* reniform, with confluent cells. *Ovary* with three divervaricating *stigmas*. *Capsule* three-horned, separating into three many-seeded *follicles*. *Seeds* compressed, winged at the apex. *(Lindley.)*

Root composed of numerous fleshy brownish-white fibres, arising from a perennial, cylindrical, fleshy, subterraneous stem or *rhizome*, which is brown externally, brownish-white internally, and is placed obliquely in the earth. *Stem* one to four feet high. The plant flowers from June to August.

Two varieties (by some considered distinct species) are included here:—

a. *albiflorum* (V. *album*, Bernh.) with decompound raceme and white flowers.

b. *viridiflorum* (V. *Lobelianum*, Bernh.) with compound raceme and greenish flowers.

**Hab.** — Mountainous regions of Europe. Abounds in the Alps and Pyrenees.

**Description.** — The *rhizome* or *cormus* (radix *veratri*, offic., *radix hellebori* *albi*) is single-, double-, or many-headed, having the form of a cylinder, or, more frequently, of a truncated cone. It is from two to four inches long, and about one inch in diameter, rough, wrinkled, grayish, or blackish-brown externally, whitish internally. Portions of the root fibres are usually attached to it, as well as some soft, fine hair-like fibres. At the upper extremity of the rhizome we frequently observe the cut edges of numerous concentric, woody, or membranous scales: they are portions of the dried leaf-sheaths. When cut transversely, the rhizome presents a large central portion (frequently called *medulla*), which varies in its qualities; being woody, farinaceous, or spongy, in different specimens. This is separated by a brown fine undulating line from a thick woody ring, in which the root fibres take their origin. On the outside of this is a narrow but compact brown epidermoid coat. The odour of the dried rhizome is feeble; the taste is at first bitter, then aerid. By keeping, the rhizome is apt to become mouldy.

The rhizome of *Veratrum viride* is used in the United States as a substitute for that of *Veratrum album* (see p. 185).

**Composition.** — White hellebore rhizome was analyzed in 1820 by MM. Pelletier and Caventou, who obtained the following results: Fatty matter (composed of olein, stearin, and a volatile [cevadic?] acid), superphallate of veratrin, yellow colouring matter, starch, ligneous matter, and gum. The ashes contained much phosphate and carbonate of lime, carbonate of potash, and some traces of silica and sulphate of lime, but no chlorides. They could not obtain the volatile [cevadic?] acid in a crystalline form.

1. *Veratrin.* *(See p. 190.)*

2. *Jermin* (so called from *Jerra*, the Spanish name for a poison obtained from the root of white hellebore); *Barytin.* — A white crystalline, fusible, and inflammable substance, discovered

*Baunin's* *Pinax*, p. 186.
VEGETABLES.—NAT. ORD. MELANTHACEAE.

by Simon. 1 It is soluble in alcohol, but not in water. With acetic and phosphoric acids it yields readily soluble salts; but, on the contrary, with sulphuric, nitric, and hydrochloric acids, it forms difficulty soluble compounds. 2 On account of its resembling baryta in being precipitable from its solution in acetic acid by sulphuric acid, it was called at first barytin. Its composition, according to Will, is $\text{C}_6\text{H}_5\text{N}_2\text{O}\text{S}_2$.

CHEMICAL CHARACTERISTICS.—A decoction of the rhizome undergoes, on the addition of a solution of gelatin, no change, showing the absence of tannic acid; but with the sesquichloride of iron, it becomes olive green (gallate of iron). With tincture of galls, it became slightly turbid (tannates of veratrum and starch). With acetate and diacetate of lead, and protonitrate of mercury, it formed copious precipitates. Oil of vitriol reddens the concentrated decoction, owing to its action on the veratrum. The rhizome left after the decoction had been prepared from it, becomes, on the addition of a solution of iodine, black (iodide of starch).

PHYSIOLOGICAL EFFECTS. a. On Vegetables.—Not ascertained.

b. On Animals generally.— The best account of its effects is contained in a thesis by Dr. Schabel, published at Tübingen, in 1817. Collecting together the experiments previously made by Wepfer, Courten, Viborg, and Orfila, and adding a number of excellent experiments of his own, he infers that it is poisonous to animals of all classes—horses, dogs, cats, rabbits, jackdaws, starlings, frogs, snails, and flies; that it acts in whatever way it is introduced into the system—by the stomach, windpipe, nostrils, pleural membrane of the chest, on external wounds, or the veins; that it produces in every instance symptoms of irritation in the alimentary canal, and injury of the nervous system; and that it is very active, three grains of the extract applied to the nostrils of a cat having killed it in sixteen hours. 72

c. On Man.—Its local action is that of a powerful acid. Applied to the Schneiderian membrane, it excites violent sneezing. Epistaxis even is said to have been induced by it. Its operation, when swallowed or placed in contact with the skin, is also that of an energetic irritant.

Its remote action is on the secretory apparatus, the stomach and intestines, and the nervous system. In small and repeated doses, it promotes secretion from the mucous surfaces, the salivary glands, the kidneys, and the uterus, and increases the cutaneous exhalation. 4 In larger doses, it causes vomiting, purging, pain in the abdomen, tenesmus, and occasionally bloody evacuations, and great prostration of strength. In some instances, a few grains even have had these effects. Schabel says there is no substance which so certainly and promptly provokes vomiting; and Horn 5 employed it as a sure emetic. In addition to the local action which it exercises, when swallowed, on the stomach and intestines, it possesses a specific power of influencing these viscera: for Etmüller 6 has seen violent vomiting result from the application of the rhizome to the abdomen; and Schröder 7 observed the same occurrence where the rhizome was used as a suppository. In excessive doses, it operates as a narcotic-acid poison, producing gastro-intestinal inflammation and an affection of the nervous system. The symptoms are violent vomiting and purging (sometimes of blood), tenesmus, burning sensation of the mouth, throat, oesophagus, stomach, and intestines, constriction of the throat, with a sense of strangulation, gripping pain in the bowels, small, and, in some cases, almost imperceptible pulse, faintness, cold sweats, tremblings, giddiness, blindness, dilated pupils, loss of voice, convulsions, and insensibility, terminating in death. A cutaneous eruption has, in some instances, followed the use of white hellebore.

I am indebted to Dr. Wm. Rayner, of Stockport, for notes of three cases of poisoning by infusion of white hellebore. The symptoms resembled those just mentioned, except that there was no purging. All three cases rapidly recovered.

5 Archiv, it. x. H. 1, S. 181.
6 Opera omnia, tom. ii. p. 344.
7 Orla, Taricel. Gen.
Hutchinson remarked that, when death did not occur, palpitation and intermitting pulse, besides dyspeptic and nervous symptoms, remained for some time.

These effects were not observed in Dr. Rayner's cases.

In its action on the system, Veratum album is more closely related to cebadilla and meadow saffron than to any other medicinal agents. It is more aerid and less stupefying than Helleborus niger, with which it has been so frequently compared both by ancients and moderns. Orfila ascertained, by experiment on animals, that it is more active as a poison than the last-mentioned substance. It exercises no known chemical influence over the tissues by which it is distinguished from the mineral irritants, as baryta and emetic tartar, with which Schabel compared it.

Uses.—It is but rarely employed, principally on account of the alleged uncertainty of its operation. But, from the few trials which I have made with it, I suspect this uncertainty is much exaggerated, and is principally referable to the varying lengths of time which the rhizome has been kept after its removal from the earth, for, like colchicum, it deteriorates by keeping. The following are the principal cases in which it has been employed:—

1. In affections of the nervous system, as melancholia, mania, and epilepsy. As an emetic, purgative, and promoter of the secretions generally, we can easily understand that it may prove occasionally beneficial.

2. In chronic skin diseases, as herpes, Dr. C. Smyth gave the tincture internally with benefit. As external applications, the decoction and ointment are used in scabies (hence the Germans call the rhizome Kratzwurzel, i.e. itch-root), tinea capitis, &c.; but their use is not quite free from danger.

3. In gout, it was given in combination with opium, by Mr. Moore, as a substitute for, or in imitation of, the Eau Medicinale. The dose, in a paroxysm of gout, was from forty minimis to two drachms of a mixture composed of three parts of Vin. Veratri albi and one part of liquid laudanum.

4. In amaurosis and chronic affections of the brain occurring in torpid habits, it is employed as an erthrine or sternutatory (hence its German name, Niesswurzel, i.e. sneeze-root). It is usually diluted with some mild powder. The German snuff called Schneebürger is said to contain it.

5. To destroy pediculi, the decoction is used as a wash.

6. As an emetic, it was employed by Horn.

Administration.—The following are the principal modes of exhibition:—

1. PULVIS VERATRI; White Hellebore Powder.—The dose of this at the commencement should not exceed one or two grains. This quantity will sometimes occasion nausea and vomiting; but Greding found that in some cases eight grains, and, in a few instances, a scruple of the bark of the rhizome in powder were required to excite vomiting. As an erthrine, not more than two or three grains, mixed with eight or ten of some mild powder (as starch, liquorice, Florentine orris, or lavender) should be employed at one time. It is a constituent of the Unguentum Sulphuris compositum (see vol. i. p. 360).

2. VINUM VERATRI, L.; Tinctura Veratri albi; Tincture of White Hellebore.—(White Hellebore, sliced, 3vii; Sherry Wine Oij. Macerate for seven days, and strain.)—As a substitute for colchicum in gout and rheumatism, the dose is ten minims twice or thrice daily. This quantity is to be gradually increased. A full dose acts as an emetic and cathartic.

3. DECOCTUM VERATRI, Ph. L. 1836; Decoction of White Hellebore.—(White Hellebore, bruised, 3x; Distilled Water Oij; Rectified Spirit 63iiij. Boil the hellebore in the water down to a pint, and when it is cooled, add the spirit.)—This preparation is only used as an external application in skin diseases (scabies, lepra,
tinea capitis, &c.), and to destroy pediculi. When the skin is very irritable, the decoction will sometimes require dilution. If the surface to which it is applied be denuded, absorption of the veratria may occur, and constitutional symptoms be thereby induced; hence it is a dangerous application, especially to children.

4. **UNGUENTUM VERATRI**, Ph. L. 1836 [Unguentum Veratri albi, U. S.]; **Ointment of White Hellebore.**—(White Hellebore, powdered, ʒij; Lard ʒvij; Oil of Lemons m. xx. Mix.)—This ointment is used in the treatment of the itch as a substitute for the disagreeable, though far more effective, sulphur ointment. Like the decoction, there is danger of the absorption of the active principle of the rhizome when the ointment is applied to raw surfaces; it is, therefore, an unfit remedy for children.

**Antidotes.**—Astringent solutions have been recommended; and in one case, which fell under my notice, infusion of nutgalls seemed to give relief. The supposed benefit has been referred to the union of tannic acid with veratria, by which the solubility and activity of the latter are diminished; but Schabel¹ found that three draehms of a tincture of white hellebore, given with infusion of galls, to a cat, proved fatal in twenty minutes. Hahnemann recommends coffee, both as a drink and in oyster. Demulcent liquids, and, in some cases, opiates, may be useful. The other parts of the treatment must be conducted on general principles. Stimulants will be usually required on account of the failure of the heart's action.

---

58. **Veratrum viride, Wild.**—**American Hellebore.**

*Sez. Syst. Polygania, Monocia.*

(Rhizoma)

The **Veratrum Viride**, U. S. (Secondary List), is known in the United States as **American Hellebore, Swamp Hellebore, Indian Poke, and Ick Weed**. It has a perennial, thick, fleshy root, tunicated at top, the lower part solid and sending off numerous white or light-yellow radi- cles. The stem is annual, from two to three feet high, pubescent. Leaves at base six inches to a foot long, broad, oval, nervèd, acuminate, of a deep green colour, and pubescent; those on the stem narrower, and, at the summit, bracteiform. Flowers in panicles, terminal, and of a greenish-yellow tint. The calyx is wanting; petals six, stamens six, pistil a rudiment (Wilde- now). Germs three, when not rudimentary, on the lower portion of the panicle.

The plant is found in many parts of the United States, from Canada to Carolina, inhabiting damp places in the neighbourhood of streams and meadows. It appears early in March.

The whole plant has an acrid and burning taste; the root only is officinal. This, when dried, consists of a somewhat tunicated top, with a thick hard base, and numerous radicles attached to it. The odour, disagreeable in the recent state, is lost by drying. The taste is at first sweetish, then bitter, followed by an acrid burning sensation in the mouth, which lasts for some hours after it has been chewed. When powdered, it acts as a sternutatory. For the composition of this root, we are indebted to Mr. Henry Worthington (American Journal of Pharmacy, vol. x. p. 97), who found it to contain gum, starch, sugar, bitter extractive, fixed oily matter, colouring matter, gallic acid, an alkaloid substance identical with veratria, lignin, and salts of lime, and potassa.

With regard to the alkaloid substance, he describes it as "nearly insoluble in water, more soluble in ether, and entirely soluble in absolute alcohol. When exposed to flame, it first melts, then swells up, and burns without residue. It produces a burning acrid sensation in the mouth, which lasts for several hours. It acts powerfully as a sternutatory, producing violent sneezing, which lasts for half an hour after it has been applied to the nose." "In its chemical relations, the analogy is carried out by not being changed to a red colour by the action of nitric acid, and from its forming salts with the acids, none of which are crystallizable but the sulphate, tartrate, and oxalate."

That the framers of the United States Pharmacopoeia have done well in the introduction of this article, is shown by the testimony in its favour as a potent medicine. Dr. Osgood (Am. Journ. of Pharm., vol. vii. p. 202), and Dr. Ware (Bigelow's Med. Bot. vol. ii. pp. 121, 132), have each instituted a course of experiments to test its remedial powers. The first found it an emetic; and the second met with a case where this effect on the stomach was produced by the application of the ointment to an ulcer on the leg. Mr. Worthington submitted himself to the test of its powers. He took the fourth of a grain of the Alcoholic Extract, which caused an acrid, burning sensation in the mouth, and communicated to the throat and fauces a sense of dryness and heat, which finally reached the stomach. In the course of about an hour, this dryness and

¹ Quoted in Brandt and Ratzburg's *Giftgewächse*, Abt. 1, S. 26.
burning sensation in the throat and stomach became intense, and a disposition to hiccough was excited, which soon commenced, gradually increasing in frequency until it reached fifteen or twenty times per minute. This was attended with some sickness and retching until vomiting took place. This was violent, and seemed to come on about every ten or fifteen minutes for the space of an hour. During this time, dizziness and tremor were created, which passed off with the effect of the dose. With the hiccough there was a copious secretion of saliva and discharge of mucus from the stomach and nose. During the action of this dose, the pulse was weakened so as to be scarcely perceptible, and reduced from sixty-eight to fifty-two pulsations per minute. (Op. cit.)

The experiment just detailed was repeated three times, and in neither was there a disposition to catharsis. The effects are those of an acro-narcotic, and not one of the least potent of this class of remedies. The uses and mode of administration are similar to those of the White Hellebore. In gout and rheumatism, the medical gentlemen before mentioned speak in its favour. A knowledge of it is stated to be possessed by the North American Indians.—J. C.

59. Veratrum Sabadilla, Retz.

*Sex. Syst.* Polygamia, Monoeccia.

(Semina.)

A native of Mexico and the Antilles. Its leaves are radical, oval-oblong, obtuse, ribbed. Its stem is almost leafless. The panicle is nearly simple. The flowers have short pedicels, and are nodding.

Its fruit and seeds are said to be brought from the Antilles, under the name of *cebadilla* (*semina sabadilla caribaea*), but I have never met with them.

60. *ASAGRÆA OFFICINALIS*, Lind.—SPIKE-FLOWERED *ASAGRÆA*.

*Sex. Syst.* Hexandria, Trigynia.

(Alkal. *semine* *parum* *atrum*, *L.*—Sabadilla; *Fruit of Veratrum Sabadilla* of Helonia* officinalis*, and probably of other Melanthacem, E.)

**SYNONYMES.—** Veratrum officinale, *Schlecht*; Helonia officinalis, *Don*.

**HISTORY.—** This plant was described by Schlechtendahl, afterwards by Mr. Don, and subsequently by Dr. Lindley. The seeds were known to Monardes in 1573. They were called *sabadilla*, or *cevadilla*, or, more properly, *cebadilla* (from the Spanish *cebada*, *barley*), on account of the supposed resemblance of the inflorescence of the plant to that of *hordeum*.

**BOTANY.**

**Gen. Char.—** Flowers polygamous, racemose, naked. *Perianth* six-partite; *segments* linear, veinless, almost equal, with a nectariferous excavation at the base, equal to the stamens. *Stamens* alternately shorter; *anthers* cordate, as if unilocular, after dehiscence shield-shaped. *Ovaries* three, quite simple, attenuated into an obscure *stigma*. *Follicles* three, acuminate, papery; *seeds* scimitar-shaped, corrugated, winged. *Bulbous herbs*, with grass-like *leaves*, and small, pale, densely-racemose *flowers* (Lindley).

**Sp. Char.—** The only species known.

*Leaves* linear, acuminate, subaurinate, roughish at the margin, four feet long, and three lines broad. *Scape* round, about six feet high. *Raceme*, a foot and a half long, very dense, very straight, spiciform. *Flowers* white, with a bractea at the base. *Anthers* yellow.

**Hab.—** Eastern side of the Mexican Andes, near Barranca de Tioselo (Schiede). Neighbourhood of Vera Cruz (Hartweg).

**Description.—** The *cebadilla*, *cevadilla*, or *sobadilla* of the shops (*sabadilla*; *semina sabadillae mexicanae*), comes from Vera Cruz and Mexico. It consists of the follicles (some containing seeds, others empty), loose seeds, stalks,

---

1. See p. 185.
3. *Linnae, vi. 45.*
and abortive flowers of the Asagracea officinalis, and perhaps of Veratrum Sabadilla also.

The follicles, commonly termed capsules, rarely exceed, or even equal, half an inch in length, and are about one line or a line and a half in diameter. They are ovate-oblong, acuminate. Their colour is pale yellowish-brown, or reddish-gray. The coat of each is thin, dry, and of a papery consistence. Each fruit is composed of three follicles mutually adherent towards the base, open at the superior and internal part. The receptacle, fruitstalk, and the remains of the dried and withered calyx, are usually present in the cebadilla of the shops. Seldom more than one or two, though sometimes three, seeds are found in each follicle.

The seeds are two or three lines long, scimitar-shaped, pointed, blackish-brown, shiny, wrinkled or corrugated, slightly winged. Internally, they are whitish or horny. Embryo straight, next the hilum, lodged in fleshy albumen. They have little odour, but a bitter, acrid, persistent taste.

**Composition.**—Two analyses of cebadilla have been made about the same time (1819); one by Meissner; and a second by Pelletier and Caventou. The following are the results:

1. **Cevadin or Sabadillie Acid.**—This is a crystalline, fusible, volatile, fatty acid, having an odour analogous to butyric acid. It is soluble in water, alcohol, and ether. It is obtained by the saponification of the oil of cebadilla (fatty matter). Cevadate of ammonia causes a white precipitate with the persalts of iron. The composition of this acid is unknown.

**Oil of cebadilla** given me by Mr. Morson is green, lighter than water, and has a faint, somewhat rancid taste.

2. **Veratric Acid**, of Merck.—This is a crystalline, fusible, volatile acid, soluble in alcohol, slightly so in water, but insoluble in ether. According to Schroetter, it consists of C\(^4\)H\(^8\)NO\(^4\) + \(\text{aq.}

3. **Resins.**—The two resins found by Meissner, but overlooked by Pelletier and Caventou, are probably endowed with activity.

Couterbo obtained from cebadilla seeds, sabadillina, helolin or resin of veratrina, and gum resin of sabadillina.

a. **Sabadillina** is a white crystalline solid, possessing alkaline properties, being soluble in boiling water and in alcohol, but not in ether. In the fused state it consists of C\(^4\)H\(^8\)NO\(^5\). It forms with acids crystallizable salts. It is said, by Simon, to be merely a compound of resinate of soda and resinate of veratrina. Dr. Turnbull found it inferior in activity to veratrina.

b. **Helolin or resin of veratrina** (Couterbo; pseudo-veratrina) is a brown solid, fusible at 365°. Insoluble in ether (by which it is distinguished from veratrina), and in water. It combines with acids; but neither saturates them, nor forms with them any crystallizable salts. It consists of C\(^4\)H\(^8\)NO\(^5\). Its action on the animal economy has not been determined.

c. **Gum-resin of sabadillina** (resinigomme, Couterbo; nonohydrate of sabadillina, Alter.) is a reddish solid, soluble in water and alcohol, but slightly so in ether. It saturates acids, but does not form crystalline compounds with them. Alkalis throw it down from its saline combinations. It consists of C\(^6\)H\(^14\)NO\(^3\). Hence it differs from anhydrous sabadillina in containing an atom more water. Furthermore, it is distinguished from this alkali in not being crystallizable.

4. **Veratrina.**—(See p. 190.)
CHEMICAL CHARACTERISTICS.—The brownish-coloured decoction of cebadilla reddens litmus, owing to the presence of free acid. Sesquichloride of iron deepens the colour of the decoction, and causes an olive brown precipitate. Alkalis deepen, whilst acids diminish, the colour of the decoction (by their action on the yellow colouring matter, Pelletier). Acetate and diacetate of lead, proconitrate of mercury, and sulphate of copper, form precipitates in the decoction. Oxalate of ammonia renders it turbid (exulater of lime). Nitrate of silver forms a coloured precipitate, which, for the most part, soluble in nitric acid: the insoluble portion is chloride of silver. Solutions of iodine and tincture of nutgalls have no obvious effect. Oil of vitriol reddens the decoction owing to its action on the veratria.

PHYSIOLOGICAL EFFECTS. a. On Vegetables.—Not ascertained.

b. On Animals.—Are similar to those of Veratrum album. Cebadilla has proved poisonous to dogs and cats. 1 A pinch of it produced violent spasms in cats; half a drachm caused vomiting and convulsions in dogs. It is a poison to insects. Thus bugs die from it in convulsions: hence its use as a bug poison. 2 Its efficacy in destroying pediculi has long been known.

7. On Man.—The action is probably similar to, though more acrid than, white hellebore. The effects of small and repeated doses have not been satisfactorily ascertained. Large and poisonous doses cause burning and pain in the throat and stomach, nausea, vomiting, purging, prostration of strength, convulsions, delirium, and sometimes a cutaneous eruption. Even the external application of the powder has caused dangerous effects. Pelletier tells us of a young man who was rendered temporarily insane by the application of powder of cebadilla to the head. Lentin says an infant, whose nurse had sprinkled the powder in its hair, died in convulsions. 3

Rubbed on the skin, the tincture causes a stinging sensation similar to that produced by veratrum. After its use for some days, a slight eruption appears on the skin. Rubbed over the cardiac region, it in some instances reduces the frequency and force of the pulse in a marked degree. The alcoholic extract has nearly the same effects, when taken internally, as veratrum. It also induces sensations of heat and tingling on the surface of the skin, and sometimes acts as a diuretic. 4

Uses.—Cebadilla has been employed internally, as an anthelmintic, in both thread-worms and tape-worms. 5 Dr. Turnbull 6 has given the extract with benefit in painful rheumatic and neuralgic affections. Though it is applicable in all the maladies for the relief of which veratrum has been recommended, it is rarely administered by the mouth.

Externally the powder of the seeds has been used to destroy pediculi; hence the Germans called the seeds Läuseesamen, or lice-seeds. But it cannot be applied with safety to children, and especially when the skin is broken. I have already referred to the dangerous consequences of its employment. The tincture has been used as a rubefacient in chronic rheumatism, and, rubbed over the heart, in some cases of nervous palpitation. 7 It may, in fact, be employed as a cheap though efficient substitute for the tincture of veratrum.

But the principal use of the seeds, for which indeed they have been introduced into the Pharmacopoeia, is for yielding veratrum.

ADMINISTRATION.—The following are the preparations of cebadilla which have been employed in medicine.

1. Pulvis SABADILAE; Pulvis contra pediculos; Poudre de Capucin; Powder of Cebadilla.—The dose for an adult is from two to six grains; gradually increased. In one case of tape-worm, half a drachm was taken daily for fourteen days. 8
2. TINCTURA SABADILLE; Saturated Tincture of Cebadilla, Turnbull.—(Cebadilla seeds, freed from their capsules and bruised, any quantity; Rectified Spirit, as much as will cover them. Digest for ten days.)—Used as a rubefacient liniment in chronic rheumatism and paralysis. It is rubbed over the heart in nervous palpitation.

3. EXTRACTUM ALCOHOLICUM SABADILLE; Alcoholic Extract of Cebadilla.—Eva- porate the saturated tincture, with a very gentle heat, to a proper consistence. Dose, 1-6th of a grain, gradually increased. It is given, in the form of pill, in rheumatic and neuralgic cases.

4. VERATRIA, L. E. [U.S.]; Veratrin; Veratrina, Thomson; Sabadillina, Meissner.—This vegetable alkaloid was discovered about the same time (1819), by Meissner in Germany, and by Pelletier and Caventou in France. Courbe had probably been the first who obtained it pure.

The process of the Edinburgh Pharmacopoeia is as follows:—

"Take any convenient quantity of Cevadilla: pour boiling water over it in a covered vessel, and let it macerate for 24 hours; remove the Cevadilla, squeeze it, and dry it thoroughly with a gentle heat. Beat it now in a mortar, and separate the seeds from the capsules by brisk agitation in a deep narrow vessel. Grind the seeds in a coffee-mill, and form them into a thick paste with rectified spirit. Pack this firmly in a percolator, and pass rectified spirit through it till the spirit ceases to be coloured. Concentrate the spirituous solutions, by distillations, so long as no deposit forms, and pour the residuum, while hot, into twelve times its volume of cold water. Filter through calico, and wash the residuum on the filter so long as the washings precipitate with ammonia. Unite the filtered liquid with the washings, and add an excess of ammonia. Collect the precipitate on a filter, wash it slightly with cold water, and dry it, first by imbibition with filtering paper, and then in the vapour bath. A small additional quantity may be got by concentrating the filtered ammoniacal fluid, and allowing it to cool.

"Veratrin thus obtained is not pure, but sufficiently so for medicinal use. From this coloured substance it may be obtained white, though at considerable loss, by solution in very weak muriatic acid, decolorization with animal charcoal, and re-precipitation with ammonia."

Cebadilla yields, to rectified spirit, veratrina in combination with a vegetable acid. Ammonia unites with the vegetable acid, and sets free the alkaloid.

By Courbe’s process, a drachm of commercial veratrina may, it is said, be procured from one pound of cebadilla.

Commercial veratrina was said by Courbe to be composed of pure veratrina, sabadillina, resin of veratrina (veratrin, Courbe), and gum-resin of veratrina (resinogomme, Courbe). These are separated from each other by the successive action of water, ether, and alcohol, as shown by the following table:—

Commercial Veratrina

yields to boiling water •

1. Sabadillina, which crystallizes on cooling.

2. Resin of Veratrina, left in the cold solution.

3. Veratrina, soluble in ether.

insoluble in boiling water

4. Gum-resin of veratrina, insoluble in ether, but soluble in alcohol.

The nature of sabadillina has been already pointed out (p. 188).

Properties.—Commercial veratrina is pulverulent, odourless, and grayish or brownish white. All the samples I have tasted were bitter and acrid, and produced a feeling of numbness and tingling when applied to the tongue. But pure veratrina is an almost white, friable solid, having the aspect of a resin: it is uncrystallizable, odourless, has a very acrid taste, without any mixture of bitterness. It is fusible at 240° F. It is sparingly soluble in ether, readily so in alcohol, scarcely so in cold water. It possesses alkaline properties: thus, it restores the blue colour of reddened litmus, and saturates acids. Its salts crystallize with difficulty: indeed, the sulphate and hydrochlorate alone have been obtained in the state of crystals; the other salts have a gummy aspect. Both the hydrochlorate and sulphate are soluble in water.

Characteristics.—Veratrina is known by the following characters: Its alkalinity, its combustibility, its uncrystallizability, the difficult crystallizability of its salts, its solidity at ordinary temperatures, its ready solubility in alcohol, its being almost

1 Ann. de Chim. et de Phys. t. 32, p. 368.
insoluble in water, and by the intense red colour which it assumes when mixed with oil of vitriol. Pure veratria is readily soluble in ether; not so, impure or commercial veratria. Nitric acid renders commercial veratria reddish, and forms a yellow solution with it (see Morphia and Narcoctina). A solution of veratria in dilute acetic acid produces a whitish precipitate (tannate of veratria) with tincture of nutgalls, a white one (hydrated veratria) with ammonia, and an intense red colour with oil of vitriol. Carbazotic acid does not occasion a precipitate unless the solution be concentrated. To these chemical peculiarities must be added those characteristics derived from its physiological effects: A minute portion of veratria causes violent sneezing, and a small quantity of a solution of four grains of veratria in a fluidrachm of rectified spirit, rubbed on the wrist or forehead, produces, within three or four minutes, heat and tingling. Pure veratria is less apt to occasion sneezing, by handling, than the impure or commercial sort.

The London College (1851) gives the following characters of veratria: Dissolves but slightly in water, more soluble in ether, but most in alcohol. It has no smell, but violently irritates the nostrils, and has a bitter taste. It is to be cautiously administered.

[The following characteristics are given by the U.S. Phar. Pulverulent, grayish-white, innocuous, but very irritant to the nostrils, and of an acrid bitter taste, causing a sensation of tingling with numbness in the tongue. It is very slightly soluble in water, but readily and wholly dissolved by alcohol. It has an alkaline reaction, and is entirely dissipated by a red heat. With nitric acid it forms a yellow solution, and, when in contact with concentrated sulphuric acid, becomes intensely red.]

COMPOSITION.—The following is the composition of pure veratria, according to Couerbe:

PHYSIOLOGICAL EFFECTS.  

a. On Animals.—Magendie has shown that the local action of veratria is that of an irritant. Placed in the nostrils of a dog, the acetate of veratria provoked violent and continued sneezing. When introduced into the intestinal canal, it caused inflammation. Applied to parts whence absorption goes on actively (as the pleura and tunica vaginalis), it occasions tetanus, and death in a few minutes. Forcke gave moderate and gradually increased doses (1/4 to 1/2 of a grain) of veratria for twenty days. It caused vomiting, and occasionally foaming at the mouth. The stools continued hard. Dr. Bardsley observed vomiting and giddiness (reeling) produced in animals to whom he gave veratria.

β. On Man.—Applied to the nose, a minute quantity excites excessive sneezing. Rubbed on the skin in the form of ointment, it causes a sensation of heat and tingling (called by Dr. Turnbull electro-stimulation). This effect is not confined to the part and its immediate neighbourhood where the application has been made; for somewhat similar sensations are occasionally experienced in distant parts.

Taken internally, in small or medicinal doses, veratria excites a feeling of warmth in the stomach and bowels, which extends to the chest and extremities. Tingling and various anomalous sensations (as of a current of hot or cold air or water passing over the skin) are perceived in various parts of the body. Nausea and vomiting are occasionally excited by a full dose. On the secretions and exhalations its action is not very uniform. It frequently produces perspiration, and not unfrequently diuresis. Forcke mentions increased secretion of saliva and of tears produced without the contact of the veratria either with the conjunctiva or mouth. The bowels are for the most part confined, so that purgatives are not unfrequently required during the use of it. Yet in some cases veratria has caused copious bilious evacuations. In

1 Fromulnire, p. 192, 8me edit.  
2 Hosp. Facts and Observ. 1829.  
3 Untersuch. uber d. Veratrin, 1837.  
some instances it has promoted, in others diminished, the appetite. Forcke mentions that a pustular eruption is sometimes induced by it. Dr. Bardsley generally found the pulse become slower and depressed after the use of veratria.

I am not acquainted with any cases of poisoning in the human subject by excessive doses of veratria. Vomiting and convulsions would probably be induced.

USES.—Veratria is employed externally or internally: sometimes in both ways at the same time. It has been tried in the following cases:—

a. In neuralgia, it has been used by Dr. Turnbull, Dr. Ebers of Breslau, and Dr. Forcke. It is applied in the form of ointment, containing from twenty to forty grains of veratria to an ounce of lard. The frictions are to be continued until the heat and tingling caused by the veratria have acquired a considerable degree of intensity. Though, according to my own experience, it fails to give relief in a large majority of cases, yet in some few its effects are highly beneficial, and in none is it injurious. As a remedy for neuralgia, it is, however, far inferior to Aconitum and its alkali Aconitina.

b. In some nervous diseases (Neuroses, Cult.).—Veratria has been extensively used in this class of diseases, but for the most part empirically. If it possess any therapeutical power, "a more extended experience is required to establish its claim to our regard." Among the maladies against which it has been used (in some instances internally, but mostly externally) are—nervous palpitation, paralysis, hooping-cough, epilepsy, hysteria, hypochondriasis, &c.

c. In rheumatism and gout.—Dr. Bardsley gave it internally in rheumatism, but with no remarkable results. Externally it has been employed in the form of ointment by Sir C. Scudamore and Dr. Turnbull. It should not be applied while the inflammation is of an active kind. It would appear to be best adapted for the neuralgic forms of rheumatism.

d. In dropsy.—Dr. Bardsley administered it internally in dropsy, but says it possesses "no particular claims to the attention of the profession." Ebers employed veratria endermically, and also in the form of ointment, epidermically. It acted as a diuretic, and gave relief.

ADMINISTRATION.—The ordinary veratria of the shops is administered in doses of one-sixth of a grain, three times a day. On account of its acridity it should not be given in solution, but in the form of pills.

a. Pilulae Veratriae; Veratria Pills; Turnbull.—Veratria gr. j; Extract of Hyoscyamus; Liquorice powder, sa. gr. xij. Let 12 pills be made, of which one may be taken every three hours.

b. Tinctura Veratriae; Veratria Embrocation; Turnbull.—Veratria 7 j; Rectified Spirit 3 j; Dissolve. This embrocation is sometimes used as a substitute for the ointment. Magendie (Formulaire) directs a tincture of veratria to be prepared by dissolving four grains of the alkali in an ounce of alcohol. Of this from 10 to 25 drops are taken, in a cup of broth, as a substitute for the tincture of colchicum.

c. Unguentum Veratriae; Veratria Ointment; Turnbull.—Veratria 3 es.; Olive Oil 3 j; Prepared Lard 3 j; M.

d. Sales Veratriae.—The sulphate and tartrate of veratria (prepared by saturating veratria with sulphuric or tartaric acid) are sometimes used instead of the uncombined alkali. The dose and mode of administration are the same as for the latter.

ANTIDOTE.—Vide Veratum Album.

ORDER XI. LILIACEÆ, Lindl.—LILYWORTS.

CHARACTERS.—Calyx and corolla both alike, coloured, regular, occasionally cohering in a tube. Stamens six, inserted into the sepals and petals; anthers opening inwards. Ovary superior, three-celled, many seeded; style one; stigma simple or three-lobed. Fruit succulent, or dry and capsular, three-celled. Seeds packed upon one another in one or two rows; embryo with the
same direction as the seed, in the axis of fleshy albumen, or uncertain in direction and position, occasionally very minute. \textit{Herbaceous} plants, shrubs, or trees, with bulbs, or tubers, or rhizomes, or fibrous roots. \textit{Leaves} narrow, with parallel veins, membranous, not articulated with the stem; either sessile or with a narrow leafy petiole.

\textbf{Properties.}—Not uniform. Mucilage, resinous matters, acrid volatile oils, and acid extractive substances, are the organic principles to which the medicinal qualities of this order are chiefly referable. Their relative proportions, however, vary considerably in different species.

The fleshy bulbs are usually more or less acidic. Those of the genus \textit{Allium} owe their acridity to a volatile oil (sulphuret of allyl) whose composition is \(\text{C}_4\text{H}_4\text{S}\) (see vol. 1, p. 253). Bundles of acicular crystals or \textit{raphides}, usually considered to be phosphate, but by Schleiden declared to be oxalate, of lime are found in some of the cells of these bulbs.

\section*{61. \textit{Aloe}, Linn.—Aloe.}

\textit{Sex. Syst.} Hexandria, Monogynia.

\textit{Succus proprius spissatus foliorum ex varis Aloe speciebus.}

\textbf{History.}—Neither aloe plants nor the inspissated juice of their leaves are mentioned by Hippocrates or Theophrastus; but both are described by Dioscorides\textsuperscript{1} and Pliny.\textsuperscript{2}

\textbf{Botany. Gen. Char.}—\textit{Perianth} tubular, six-cleft, fleshy, nectariferous at the base, the sepals of the same form as the petals, and closely imbricating them. \textit{Stamens} hypogynous, as long as the perianth, or even longer. \textit{Capsule} membranous, scarious, three-corned, three-celled, three-valved, with a loculicidal dehiscence. \textit{Seeds} numerous, in two rows, roundish or angular. (Lindley).—Succulent plants.

\textbf{Species.}—The following species furnish the greater part of the substance called in the shops \textit{aloe}:

1. \textit{Aloe vulgaris}, Lam. L. D.; \textit{Aloe perfoliata}, \textit{vera} Linn.; \textit{A. bardadensis}, Miller, Haworth; \textit{Aloë}, Dioscor. Sibth.—\textit{Stem} woody, simple, cylindrical, short. \textit{Leaves} fleshy, amplexicaul, first spreading, then ascending, lanceolate, glaucous, green, flat above, convex below, armed with hard, distant, reddish spines, perpendicular to the margin; a little mottled with darker colour; the parenchyma slightly coloured brown, and very distinct from the tough leathery cuticle. \textit{Scape} axillary, glaucous reddish, branched. \textit{Spike} cylindrical-ovate. \textit{Flowers} at first erect, then spreading, afterwards pendulous, yellow, not larger than the stamens. (Lindley).—East Indies, Barbary, Spain, Italy, Sicily, Malta, Greece, West Indies.

Specimens of this species are frequently brought to London from the West Indies by sailors, a tattered cloth being closely tied around the truncated stem to prevent the escape of the juices of the plant. If suspended by a cord from the ceiling of a room, they continue to live for a considerable time, and throw out fresh leaves. I have had one in my possession for nearly two years, and it is still living and growing.

This species yields \textit{Barbados aloe} (\textit{Aloe Bardadensis}, Ph. Lond.).—The brownish-yellow, bitter, resinous juice which, by inspissation, forms aloe, is contained in parallel greenish vessels beneath the epidermis of the leaves.

2. \textit{Aloe arborescens}, Lam. is by some writers considered to be a variety of \textit{A. vulgaris}. By Kunth it is regarded as a distinct species. Its flowers are greenish yellow. It is a larger and more resinous species than the preceding, and was brought from Africa by Bruce. It may, perhaps, yield a portion of the aloes of commerce. It contains a very bitter juice, which becomes brown in the air.

3. \textit{Aloe succotrina}, Lam. De Cand.—\textit{Stem} woody, straight, one and a half feet high or more, naked below, where it is strongly marked with the scars of leaves. \textit{Leaves} amplexicaul, ascending, ensiform, green, curved inwards at the point, convex below, rather concave above, marked with numerous small white marginal serratures, the parenchyma abounding in a bright brownish-yellow juice. \textit{Raceme} cylindrical, unbranched. \textit{Flowers} scarlet at the base, pale in the middle, green at the point. \textit{Stamens} unequal, three of them longer than the flowers. (Lindley).—Soeotra; also, according to Nees von Esenbeck, Cape of Good Hope.

\textsuperscript{1} Lib. iii. cap. xxv.

\textsuperscript{2} Hist. Nat. lib. xxviii. cap. v.
VEGETABLES.—NAT. ORD. LILIACEAE.

Lieut. Wellsted\(^1\) says that the hills on the west side of Socotra are covered for an extent of miles with aloe plants; and he observes that it is not likely, at any future period, that the whole quantity will be collected which might be required.

It is said to yield socotrine (and real hepatic?) aloe.—Under the epidermis of the leaves are parallel greenish vessels containing the bitter resinous juice, as in the last-mentioned species. By drying, the leaves of A. socotrana (like those of A. purpurascens, but unlike those of A. vulgaris) acquire a purplish-red colour, which commences first in the parallel vessels, and is probably produced by the oxidation of the resinous juice contained in these vessels.

4. A. purpurascens, Haworth.—This species has dark red flowers and glaucous leaves, which become purplish-red when drying. It has the same localities as the last-mentioned species. Its juice is very bitter and resinous, and becomes blood red in the air.

5. Aloe spicata, Thunb. D.—Stem three to four feet high, as thick as a man's arm. Leaves thick, fleshy, broad at the base, gradually narrowing to the point, channelled, full two feet long, distantly toothed, with a few white spots; their parenchyma almost colourless. Spike a foot long, very compact, with the flowers campanulate and horizontal. The three petals broader, ovate, obtuse, white, with a triple green line, the sepals narrower, less conave. Stamens much longer than the perianth. The flowers are filled with a purplish honey. (Ivindley.)—This species is a native of the interior of the Cape of Good Hope, and contributes to yield Cape Aloes. Thunberg\(^2\) states that it yields the best hepatic aloes, ("sucus Aloes hepaticus purus et optimus.")

6. Aloe ferox, Lam.—Stem very lofty. Leaves perfoliate, thick, juicy, sword-shaped, deflexed, glaucous, prickly throughout, but bearing larger and sharper spines along the margins. Flowers racemose, crowded. Stamens double as long as the corolla. L. Pappe, Fl. Capensis Med. Prodr.—A native of Swellendam, Cape of Good Hope. Yields the best Cape aloes.

7. Aloe Africana, Miller.—Yields Cape aloes almost equally good with A. ferox, but not so bitter, nor so powerful a drastic.

8. Aloe plicatilis, Miller.—Inhabits the mountainous range near the Paarl, Drakenstein, and Fransche Hock, at the Cape of Good Hope. It yields the aloes commonly used by the colonists, which is milder than the preceding, and much resembles Barbados aloes.

Other Species.—It is probable that several other species contribute to the supply of the aloes of commerce. I have received four species from Mr. Dunsterville, of Algoa Bay, who writes that from all of them, as well as from other species, the so-called Cape aloes is obtained. Thunberg\(^3\) states that A. perfoliata yields a large quantity of aloes at the Cape, and he also says\(^4\) that A. linguaformis, Linn. yields the best and purest sort. Dr. Christison\(^5\) suggests that A. Commelini of Wildenedow may yield some. He was informed, by Mr. John Lyell, that at Swellenden and George (South Africa), aloes is obtained from A. spicata, A. Africana of Haworth, and varieties of these crossed with A. ferox. The last-mentioned species is now cultivated in Barbados, according to Schomburgk.\(^6\)

In Arabic, Forskål found A. officinalis (A. rubescens of De Candolle?), whose juice had the odour of the official socotrine aloes. Its flowers were red.

In India, there is also a species with reddish flowers, which Dr. Royce\(^7\) has called A. Indica. This, if known to Roxburgh, was probably included by him in A. perfoliata.

Nees von Esenbeck mentions the following species as being rich in a bitter resinous juice: A. humilis, Lam.; A. Ferra, De Cand.; A. ferox, Lam.; and A. subferox, Spreng. He also found that the following were feebly bitter, but in different degrees: A. glauca, Mill.; A. paniculata, Jacq.; A. saponaria, Haw.; A. canta, S. D.; A. plicatilis, Mill.; A. arborescens, Mill.; and A. frutescens, S. D. He says that A. glauca, Mill. was also slightly bitter, but that the juice became

---

2. Dissertatio Botanica Medica de Aloa, 1765.
5. Flora Egyptiaco-Arabica, p. 72, 1775.
Aloes:—Preparation.

195
dark brown in the air, which shows that this colouring matter is a peculiar principle originally different from the bitter matter.

Preparation.—The finest kind of aloes is obtained by evaporating the juice which flows spontaneously from the transversely-cut leaves. This juice is lodged in vessels running longitudinally beneath the epidermis. The exudation of it is promoted by gravity, by dipping the leaves in hot water, and by making fresh sections of the leaves. But if pressure be employed, the proper aloetic juice becomes mixed with the mucilaginous liquid of the leaves, and thus an inferior kind of aloes is obtained. A still commoner variety is procured by boiling the leaves, from which the juice has been previously allowed to escape, in water.

a. Of Socotrine Aloes.—In the Island of Socotra the leaves are plucked at any period, and by any one who chooses to take the trouble; and after being placed in a skin, the juice is allowed to exude from them. The following mode of preparing socotrine aloes, as related by Hermann, was communicated to Ray by Dr. Palmer: *

*When the leaves which have been pulled from the roots are gently compressed by the hand or an instrument, the juice drops from them into a receiving vessel; and being allowed to stand during a night deposits the grosser parts. The next day it is transferred to another vessel, in which it is exposed to the sun that it may harden and become dry, when it acquires a brownish-yellow colour."

3. Of Barbados Aloes.—In Barbados, the aloes is best procured in the month of March. It is obtained as follows: "Every slave hath by him three or four portable tubs. The leaves being cut near the roots, are thrown into these with their broken ends downwards; and as the leaves are full of large longitudinal veins or vessels, they yield an easy passage to the juice (which is of a greenish-yellow colour) to drip out. This being boiled for about five hours in a copper or kettle, the watery particles evaporate, and the remainder comes to a consistency and thickening as sugar doth when sufficiently boiled. The way to know when it is enough boiled is, to dip a stick in the liquor, and observe whether the aloe-sticking to it, when cold, breaks short: if it doth, then it is boiled to perfection, and fit to be poured into gourds or calabashes, or other vessels, for use."  

Dr. Wright* says, that in Jamaica, the leaves contained in hand-baskets or nets are boiled in water, and the strained liquor evaporated to a proper consistence, and then poured into gourds or calabashes. Dr. Patrick Browne, on the other hand, states that the sun-dried juice is called socotrine aloes; but the common aloes, he adds, is obtained by squeezing out the juice by the hand, adding water to it, and boiling down to a proper consistence.

γ. Of Cape Aloes.—The method of preparing aloes followed at the Cape of Good Hope has been described by Thunberg, ¹ Lieut. Moody, ² and others. ³

Mr. George Dunsterville, surgeon of Algoa Bay, and formerly one of my pupils, has furnished me with the following information respecting the manufacture of Cape aloes: "A shallow pit is dug, in which is spread a bullock's hide or sheep's skin. The leaves of the aloe plants in the immediate vicinity of this pit are stripped off, and piled up on the skin, to variable heights. These are left for a few days. The juice exudes from the leaves, and is received by the skin beneath. The Hottentot then collects in a bucket or other convenient article the produce of many heaps, which is then put in an iron pot capable of holding 18 or 20 gallons. Fire is applied to effect evaporation, during which the contents of the pot are constantly stirred to prevent burning. The cooled liquor is then poured into wooden cases of about three feet square by one foot deep, or into goat or sheep skins, and is thus fitted for the

¹ Welstend, op. citato. ² Dale, Pharmacologia. ³ Hughes, Natural History of Barbados, p. 134, 1780. This account is further confirmed by that of Mr. Millington, Lond. Med. Journ. vol. viii. p. 422. But Dr. Chrisslen states, the Barbados aloe of the present day is the extract of a decoction.

market. In the colony, aloes realizes about 24d. to 34d. per lb." Mr. Dunsterville also informs me that the Hottentots and Dutch boors employ indiscriminately different species of Aloe in the preparation of Cape aloes. He adds, that "the Cape aloes, which is usually prized the highest in the English market, is that made at the Missionary Institution of Bethelsdorp (a small village about nine miles from Algoa Bay, and chiefly inhabited by Hottentots and their missionary teachers). Hence it is called Bethelsdorp Aloe. Its superiority arises, not from the employment of any particular species of Aloe, for all species are indiscriminately used; 'but from the greater care and attention paid to what is technically called 'the cooking of the aloes,' that is, to the evaporation, and to the absence of all adulterating substances (fragments of lime-stone, sand, earth, &c.) often introduced by manufacturers.'

DESCRIPTION AND VARIETIES.—I am acquainted with seven commercial varieties of aloes; namely, Socotrince, Hepatic, Barbados, Cape, Mocha, Caballine, and Indian. To these must be added Curacoo Aloe.

The terms socotrince, hepatic, and caballine, have been used to indicate rather the quality and purity, than the origin, of aloes. Thus Thunberg says, "Pro diversa puritate potius, quam quidem eun origine, triplicem imprimis Aloe's speciem in Pharmacopelia nostri introductum invenimus, scilicet socotrinam, hepaticam, et caballinam." And Jussieu states that he saw all three varieties prepared at Morvidero, in Spain, from the Aloe vulgaris.

The term Aloe lucida, or clear aloe, has been applied by Schroeder, Geoffroy, Fécé, and others, to a clear or transparent aloe supposed to be formed by the concretion of the juice on the leaves after they have been incised. It is probable that by this term are meant the clearest and most transparent pieces of socotrince aloes. I have never met with, in English commerce, any aloe by this name: and a similar remark has been made by Alston.

1. Socotrince Aloe (Aloe socotrina, L.; Aloe socotrina and Aloe Indica, E.). A few years ago this kind of aloe was brought by way of Smyrna, and hence was frequently termed Turkey aloes. But since the expiration of the charter of the East India Company, it is usually brought by way of Bombay. It is the kind sold at Apothecaries' Hall, London, and at other places under the name of extract of spiked aloes (extractum aloes spicatum), although there is no evidence of its being obtained from Aloe spicata. The London College (1851) states it to be the juice of the cut-off leaves, dried in the air, of an uncertain species of aloe. It comes over in skins contained in casks (holding from 11 to 15 cwt. each), kegs, and chests. Its consistency and colour are subject to considerable variation. The exterior portion of each skifful is usually hard, but the internal portion is frequently soft or even semi-liquid.

The hardened portions vary in colour in different parts of the same mass; sometimes they are garnet red, at other times much paler, and when quite dry are golden red, and yield a golden yellow powder. By exposure to the air the colour is deepened. The fracture of fine selected pieces is smooth, glassy, and conchoidal; but socotrince aloes of excellent quality often breaks with a roughish fracture. The finest kind of socotrince which I have met with had the semi-transparent red colour observed when we break a fine tear of myrrh. Thin films of pure and hardened socotrince aloes are usually translucent or nearly transparent. The fragments, which have a ruby colour, are called aloe socotrina vera. The odour of fresh broken pieces (especially when breathed on) is very fragrant, and is much stronger in recent and soft specimens. The same agreeable odour is obtained by heating the aloes on a point of a knife in a candle. By distillation with water, we obtain a liquid having the same odour, but free from any bitter taste. When fresh, socotrince aloes pos-

4 Tractatus de Materia Medica, t. ii, p. 849, 1714.
5 Cours d'Hist. Nat. Pharm. t. i. p. 327, 1825.
7 I have received from Dr. D. Macleod, Lecturer on Materia Medica in Edinburgh, two specimens of aloes; one marked "True Socotrince Aloe, garnet red in their fragments," the other "Aloe given to me as True Socotrince, rough fracture nearly garnet red in thin fragments. Included under Aloe indicum, Ed. Pharm." Both kinds are Socotrince aloes.
8 I am informed that they are the skins of the Gazelle.
Socotr ine Aloes; Hepatic Aloes.

197

sesesses considerable acidity, and the late Mr. Hennell informed me that, in the preparation of the compound extract of colocyn rh, he had frequently observed the fatty acid of the soap set free by the acid of the socotrine aloe. I have been shown a sample of what was declared to be socotrine aloe, which was soft or semi-liquid, and had a bright or palm-oil yellow colour, and a very fragrant odour.

When a package of socotrine aloe arrives at a druggist warehouse, it is usually garbled or sorted. The finest, clear, and hard pieces are separated for sale. The soft portions are placed upon slabs or in shallow tin trays, or other vessels, and exposed to a very gentle heat to harden them (hardened socotrine aloe), and at the same time to preserve the favourite colour of this kind of aloe. Mr. Whipple, who has had great experience in these matters, informs me that “the loss would be frightful, if, after selecting or separating the clean aloe, the skins were not washed and the aloe obtained by subsequent evaporation.”

It is brittle, bitter, reddish brown, with an aromatic odour; fresh thin films of it are translucent. Ph. Lond.

“In thin pieces, translucent, and garnet red; almost entirely soluble in spirit of the strength of sherry. Very rare.” P. Ed.

But socotrine aloe as imported is not “in thin pieces;” this character being given to it in the garbling process, or by drying the soft portions in thin layers as above mentioned. Translucency and a garnet red colour are qualities not possessed by many fine specimens of socotrine aloe. The alcoholic strength of sherry is subject to variation, and, therefore, the statement of the College as to the solubility of socotrine aloe is not very definite. Lastly, as to socotrine aloe being very rare, I may observe that the late Mr. Hennell, of Apothecaries’ Hall, informed me (Dec. 21, 1841), that he would be happy to take an order for 500 lbs. of it.

The impure and dirty pieces of socotrine aloe are sometimes melted and strained (strained socotrine aloe), by which the colour and odour are impaired, and the other qualities somewhat altered.

Socotrine aloe has long been regarded as the best kind of aloe, though its commercial value is now below that of Barbados aloe. It is, I suspect, inferior in activity.

Socotrine aloe is mentioned by Avicenna and Mesue, both of whom regarded it as the best kind. By Fée, and some other continental writers, it is confounded with Cape aloe.

The aloe prepared in the Island of Socotra is probably procured from Aloë socotrina; and perhaps also A. purpurascens. In 1833, the quantity exported from this island was 85 skins, or 2 tons. But a much larger quantity might be procured if required. Two samples (one of which I have in my museum) brought direct from the Island of Socotra, by a friend of Professor Royle, are largely intermixed with foreign substances, as sand, skins, &c.

Sir Whitelaw Ainslie says, that the greater part of the extract now sold under the name of socotrine aloe is prepared in the kingdom of Melinda; and I am informed by an eminent drug merchant that both socotrine and hepatic aloe have been imported into London directly from Zanzibar.

2. Genuine Hepatic Aloe; Liver-coloured Socotrine Aloe (Aloë hepatica, L. D.; Aloë Indica, E.).—This sort of aloe usually comes to London from Bombay (hence it is sometimes called Bombay or East India Aloe) in skins, contained in casks holding from 200 to 300 pounds, or in kegs. The London College (1851) declares it to be the “inspissated juice of the leaf?” of “an uncertain species of aloe.” Its odour is very much the same as that of the socotrine kind, or perhaps it is a little

1 Cours d’Hist. Nat. Pharm. t. i. p. 265.
4 I suspect hepatic aloe is included by the Edinburgh College under “Aloë Indica.” For, in preparing Deception of Aloes, the College orders Socotrine or Hepatic Aloes, though the term hepatic does not occur in the list of Materia Medica.
5 Mr. Whipple informs me that it is “received in packages varying from 50 lbs. to 12 cwt. casks, most commonly in Årkins. Lately, it has come over in boxes lined with tin, and holding about 50 lbs. All of these, except the last, contain the skin packages.”
VEGETABLES.—

less fragrant. It is distinguished from the latter by its opacity and its liver colour. It might, therefore, be called opake liver-coloured socotrine aloe. It appears to me to bear very much the same relation to the transparent or real socotrine aloe that the opake yellow resin bears to the dark transparent or fiddler’s resin. It is sometimes imported in a soft or liquid state, and in this condition I know not how to distinguish it from liquid socotrine aloe. The similarity of the odour of socotrine and hepatic aloe leads to the suspicion that they are obtained from the same plants; and which is further confirmed by the two being sometimes brought over intermixed, the socotrine occasionally forming a vein in a cask of hepatic aloe. Some samples of hepatic aloe, when digested in rectified spirit of wine, yield a tincture, at the bottom of which there remains undissolved a yellowish granular powder (in appearance something like lycopodium), which is insoluble in water, alcohol, ether, and dilute sulphuric acid, but is readily soluble in a solution of caustic potash, forming a red-coloured liquid.

The place of produce of this species is probably the same as that of the so-called socotrine aloe.

Opake, liver-coloured, bitter, with an unpleasant odour. Ph. Lond.

3. Barbados Aloe; Aloe in gourds (Aloë barbadensis, Ph. L. and Ed.)—This is the kind denominated by most continental writers (as Geiger, Theod. Martius, Pfaff, Fée, and others), hepatic aloe (aloe hepatica), but its colour is not constantly that of the liver. It is imported from Barbados or Jamaica usually in gourds (Lagenaria vulgaris), weighing about 60 to 70 pounds, or even more than this; and sometimes in cases or boxes holding 56 lbs. each. The hole in the gourd-shell is partially closed by a piece of gourd let in and covered by a portion of coarse cloth, which is nailed down over the aperture.

The finest Barbados aloe is the inspissated juice, which I have heard called by an inhabitant of the island cold drawn Barbados aloe, to distinguish it from the extract of the decoction, which is of inferior quality.

Barbados aloe varies in colour from a dark brown or black (brown or black Barbados aloe) to a reddish-brown or liver colour (liver-coloured or hepatic Barbados aloe): even in the same gourd a difference of colour is occasionally observed. The fracture also varies, sometimes being dull, at other times glossy, or even resinous. Its unpleasant odour (which is much increased by breathing on it) will always distinguish it from the foregoing kinds. Its powder is of a dull olive-yellow colour. This kind of aloe is obtained chiefly, if not exclusively, from the Aloë vulgaris.

The London College (1851) declares it to be the “inspissated juice of the cut-off leaves of Aloë vulgaris.”

Opake, not glistening, liver-coloured, becoming blackish, with a bitter nauseous taste, and very unpleasant odour.—Ph. Lond.

The quantity of aloe annually exported from Barbados is stated by Sir R. H. Schomburgk (op. cit. pp. 140, 150, and 160) to be as follows:

4. Cape Aloe (Aloë capensis; A. lucida of Geiger).—This kind is imported, as its name indicates, from the Cape of Good Hope. It is brought over in chests and skins, the latter being preferred, as the aloe contained therein are usually purer

1 Dr. Maycock (Flora Barbadosis, 1830) notices no other species of Aloë indigenous, naturalized, or cultivated in Barbados. But Dr. Christian observes that, though at one time Barbados aloe was made only from A. vulgaris, he is assured by various pupils from that island that, while this species is commonly used, others are likewise employed. Sir R. H. Schomburgk (History of Barbados, p. 590, 1847) mentions A. ferox, Lam. or Great Hedge-hog Aloe, as having been introduced from the Cape of Good Hope. Kuhn (Enum. Plant.) says, but I know not on what authority, that A. socotrina is cultivated at Barbados.
and more glossy. It has a shining resinous appearance, is of a deep brown colour, with a greenish tint, and has a glossy or resinous fracture; its edges, or thin laminae, viewed by transmitted light, have a yellowish red or ruby colour; its odour is stronger and more disagreeable than the Barbados aloes; its powder is greenish yellow. Some of the commoner kinds of Cape aloes have a rough fracture. The finest kind of Cape aloes is called Bethelsdorp aloes (see ante, p. 196).

Occasionally it has been imported of a reddish-brown colour, like that of the liver, and opake (liver-coloured or hepatic Cape aloes). Some years since an experienced dealer bartered 3 lbs. of Cape aloes for 1 lb. of what he thought to be the genuine hepatic aloes, but which turned out to be a fine sort of Cape aloes. I presume this is the kind which Professor Guibourt, to whom I sent a specimen of it, formerly termed false hepatic aloes; and which more recently he calls opake Cape aloes. Its odour, when breathed on, instantly detects it.

I have received four species of Aloë plants from Mr. Dunsterville, of Algon Bay, and the four extracts which he was informed were obtained respectively from the species sent. Two of the plants were dead and rotted; and the others were unknown to the late Mr. Anderson, of the Chelsea Gardens. The four extracts are as follows:

a. Ordinary Cape Aloes.—Dark, glossy, very resinous, with a strong disagreeable odour, and greenish tint.

b. Soccotrine Cape Aloes.—This, in colour, resembled soccotrine aloes; but it was more glossy, brittle, and transparent. Its odour, though disagreeable, was less so than the first kind.

c. Hepatic Cape Aloes.—This is an intermixture of an opake liver-coloured extract (hepatic Cape aloes) with a dark, glossy, transparent extract.

d. This very much resembled the preceding, and might equally claim for its opake portion the name of hepatic Cape aloes.

Cape aloes is procured from Aloë specicata and other species (see ante, p. 194).

5. Fetid, Horse, or Caballine Aloes (Aloë caballina).—I have never met with any particular kind of aloes under this name in English commerce; Barbados aloes being used in England for horses. From Prof. Guibourt I have received two substances, which he denominates Aloës Caballin.

a. One is impure or foot Cape aloes.

b. The other is in black opake masses, intermixed with straws, pieces of bark, sand, charcoal, and other impurities. Its fracture is uniform. It is difficult to pulverize, adheres to the pestle, gives a greenish powder, has a very little odour, and yields a dark brown decoction. It is probably an extract prepared by boiling the leaves in water.

Guibourt says Caballine aloes is procured either in the countries which furnish ordinary aloes, or in Spain or Senegal.

6. Mocha Aloes (Aloë de Mochâ).—Under this name, I found in a drug warehouse, where it had lain for many years, an impure kind of aloes, in large irregular masses, opake, and black externally, intermixed with sand, strings, &c. In its brittleness, odour, and the pale colour of its decoction, it resembles Cape aloes. The interior of the mass is not uniform: in some places it is dark and opake, somewhat like Barbados aloes; in other places it resembles soccotrine aloes, and here and there we find portions having the transparency and resinous appearance of Cape aloes. Recently, this kind of aloes has been imported under the name of Mocha aloes from Muscat, in chests containing nearly 2 cwt. each. Dr. Christison thinks it is East Indian aloes of low quality. It is described by Guibourt under the name of blackish or fetid aloes (aloës noirâtre et fétide).

7. Indian Aloes (Aloë indica; not the Aloë indica of the Edinburgh Pharmacopoeia).—Dr. O'Shaughnessy mentions two kinds of Indian aloes: Kurachee aloes, nearly black, opake, and soluble in water to the extent of 52 per cent.; and Deckan aloes, deep brown, and soluble to the extent of 98 per cent. 

Footnotes:
3 Hist. des Drog. simpl. 3me édit. t. ii. p. 418.
3 Ibid. 4me édit. p. 106.
4 Formerly the inhabitants of Morviedro, in Valencia, cultivated the aloes plant (A. esgaviaris), and obtained from it three kinds of aloes, called respectively soccotrine, hepatic, and caballine (Jussieu in Chaplin's Elements of Chemistry, vol. iii. p. 69); but Laborde (Vues de Spain, vol. i. p. 304, 1808) says the cultivation is now neglected.
5 Dr. Whipple tells me, that in dissolving and straining Mocha aloes, he has never found less than 25 per cent. of impurities (sand, stones, &c.).
Through the kindness of Professor Royle, I have examined four kinds of aloes brought from the interior of India:

1. **Aloes from Northern India.**—Is dull, black, and brittle, and has little odour. It came from the northern parts of India, where it is common in the bazaars (Bazaar aloes). It is probably the kind which Ainallie says resembles Barbados aloes, and is brought to India from Yemen, in Arabia. Is this the produce of *Aloe officinale*, Forskål?  

2. **Guzerat Aloes.**—Is dark, more gummy in its appearance and feel, more difficult to fracture.  

3. **Salem Aloes.**—In blackish masses. It was brought from Salem. It is distinguished from all the preceding by the numerous large air cavities observed in its interior. Its odour is analogous to that of socotrine aloes. Its price is marked one anna and nine pice [about two-pence halfpenny] a pound.  

4. **Trichomanes Aloes.**—Resembles Cape aloes in its brittleness, odor, and colour, but is more opaque. Its price is marked at two annas [about three-pence] a pound.

These aloes are the produce, in part at least, of *Aloe indica*; a species with reddish flowers, common in dry situations in the northwestern provinces of India, and which, if known to Roxburgh, was included by him in the *A. perfoliata*, Linn., and perhaps also of *A. vulgaris*, or the plant mentioned by Rhexed.  

5. **Curacoa Aloes.**—This species of aloes is not known in the London market, but a notice of it has been published by Mr. A. Faber. It is the produce of the Dutch West India Island, Curacoa; but as even in Holland it cannot be regularly obtained, it is probable that its production is scanty.

It is most like Cape aloes, but does not possess the greenish colour which is sometimes perceived in the latter; its appearance is more dull; and its colour is often that of the liver. From hepatic aloes it differs by its saffron-like odour. It is probably the produce of *A. vulgaris*.

**Powdered Aloes.**—In January, 1846, the lecture assistant of the Pharmaceutical Society carefully powdered selected samples of five kinds of aloes in the Society’s museum. The colour of the various powders were as follows:

<table>

**Strained Aloes; Aloë colata.**—In order to deprive aloes of the various foreign matters with which they are frequently mixed, the wholesale druggist purifies the extract by melting and straining it. The fusion is effected in a metallic vessel heated by steam or hot water, a hair or wire sieve being used for straining the liquor. By this process the aloes suffers a physical, and probably also a chemical change. It becomes darker coloured, harder, and somewhat less odorous. It is probable that the deepened colour is produced by the action of atmospheric oxygen.

**Composition.**—Aloes has been analyzed by Trommsdorff, by Bouillon-Lagrange and Vogel, by Braconnot, and by Winkler.

4.引自 p. 155.  
Aloes:—Chemical Characteristics.

1. Aloesin, Pfaff (Saponaceous Matter; Extractive; Bitter Principle of Aloe or Aloe bitter; Aloin).—This is the principal constituent of aloe. It is contained in the cold infusion of aloe, and also in a decoction which has cooled: it may be obtained from either by evaporation. Thus procured, it is a brown and bitter mass, readily soluble in water, but difficultly so in spirit of wine. In pure alcohol or ether it is said to be insoluble, or nearly so. Besides carbon, hydrogen, and oxygen, it contains nitrogen, for it yields ammonia by destructive distillation, and furnishes carboxylic acid when treated by nitric acid. Aloesin is probably a mixture or compound of various proximate principles. Obtained as above, Braconnot says it contains some of the puce-coloured principle, which may be removed by oxide of lead.

2. Aloe Resin.—The substance which deposits from a decoction of aloe as it cools is usually denominated resin. Braconnot says it is a mixture of aloesin and puce-coloured principle; while Berzelius regards it as apothéme combined with unaltered extract. It is transparent, brown, fusible, soluble in alcohol, ether, and alkaline solutions. The puce coloured principle of Braconnot is an odourless and tasteless powder, combustible, but not fusible; and is prepared by digesting aloe with water and oxide of lead: a compound of the puce principle and the oxide is procured, which is to be washed and decomposed by weak nitric acid: the oxide is dissolved, and the puce principle left. From Braconnot's observations, this principle seems to be rather oxidized extractive (apothéme, Berz.) than resin.

3. Vegetable Albumen.—This term is applied to a substance insoluble in both water and alcohol.

4. Aloeic Acid.—This is the acid which Trommsdorff supposed to be gallic acid. A solution of aloe reddens litmus, darkens ferruginous solutions, but does not precipitate gelatin: hence Trommsdorff assumed the presence of gallic acid. But while gallic acid causes a blue colour with the persulphate of iron, infusion of aloe produces an olive brown one. Furthermore, if excess of diacetic of lead be added to this infusion, and sulphured hydrogen be passed through the filtered liquor, to throw down the excess of lead, the boiled and strained liquor possesses the property of becoming olive brown on the addition of sesquichloride of iron. Hence it appears to me that the acid is a peculiar one, and I have accordingly termed it aloeic acid. It must not be confounded with an acid obtained by the action of nitric acid on aloe, and which has been termed aloetic acid.

Meissner has given the name of Aloine to a supposed alkali in aloe. Its solution was brown, and acted as an alkali on redened litmus paper. With sulphuric acid, aloine formed a crystalline salt.

Winkler regards aloe as a neutral vegetable salt, composed of two peculiar basic substances (viz., a non-bitter resin, and a bitter substance) and an acid, viz., a colouring, non-bitter matter.

Fabron obtained a fine violet colour from the recent juice of the Aloë, which has been proposed as a dye for silk. It is formed by the action of the oxygen of the air on the juice.

Messrs. T. and H. Smith have obtained a yellow crystalline substance from aloe, to which they have given the name of aboiné. Its composition is stated by Dr. Stenhouse to be CH11BO3. In doses of one or two grains it operates as a purgative.

Chemical Characteristics.—Aloe is almost completely soluble in boiling water. When the decoction of aloe cools, the substance called resin is deposited. The clear cold solution (aloesin) reddens litmus, strikes a deep olive-brown tint (aloesate of iron) with sesquichloride of iron, is deepened in colour by alkalies, but is unchanged with gelatine. Diacetate of lead forms a copious yellow precipitate with it.

The alcoholic tincture of aloe does not become turbid when mixed with water. When the ethereal tincture is poured in water, the ether evaporates, and leaves a film of resin.

The bitter principle of aloe (aloesin) is distinguished from that of rhubarb by its not striking a green colour with the salts of iron, and by its insolubility in ether.

The differential chemical characters of the various kinds of aloe are not constant. The following, however, are the results of some experiments:

a. Cape aloe, when good, usually completely dissolves in boiling water, leaving no residuum of vegetable albumen, &c. The decoction is clear, usually paler than that of the other kinds, and deposits much of the so called resin in cooling.

b. Barbados aloe sometimes leaves an insoluble residuum (vegetable albumen, &c.) when boiled in water. The decoction, when cold, is dark and usually turbid: generally, it is darker than that of the other sorts, yet I have found it the palest. I have also observed that the

2 Ann. de Chim. xxvi. 301.
3 Schwartz, Pharm. Tabell. p. 291, 2to Aug.
4 Chemical Gazette, March 15, 1853.
decoction on cooling becomes turbid, and lets fall a yellow powder like that which I have seen in decoction of hepatic aloe.

γ. Socotrine aloe yields a decoction which, when cold, is dark and nearly clear.

δ. Hepatic aloe yields a decoction which, on cooling, frequently deposits a yellow powder.

Products of the decomposition of aloe by nitric acid.—When aloe is heated with nitric acid, nitrous fumes are evolved, and the principles of which aloe consist are oxidized. The residuum has an intensely bitter taste, and is termed artificial aloe-bitter (künstliches Aloeental.) It is a mixture of several principles.

The products of the action of nitric acid on aloe have occupied the attention of several distinguished chemists; but the results of their experiments, though highly interesting, are not uniform. Braconnot¹ and Chevreul² examined the reaction. The former applied the term aletic acid to the residual solid, which Liebig³ subsequently declared to be a mixture of nitric or nitrous acid, carbazotic acid, and a peculiar, non-acid, reinos, red matter. Boutein⁴ has more recently examined the reaction of nitric acid on aloe, and he states the products to be polyhydroxylic acid (the aletic acid of Braconnot) composed, according to Pelouze, of C₄H₅NO₂⁵, oxalic acid, carbazotic acid, and cyanide. Schunk⁶ states that, by the action of nitric acid on aloe, he obtained four peculiar acids, viz., aletic acid, aloetrisic acid, chrysemic acid, C₄H₅NO₂+HO, and chrysolepic acid, C₄H₅NO₂-HO.

Mallet⁷ has recently examined the products of the reaction of nitric acid on aloe. Anhydrous chrysemic acid, he says, consists of C₄H₅NO₂. The so-called chrysolepic acid he considers to be identical with nitroperic acid (i.e. carbazotic acid). He found the composition of the foliaceous crystals of this acid to be C₄H₅NO₂.

Physiological Effects. a. On Vegetables.—Not ascertained.

β. On Animals.—Aloe is the ordinary purgative for solipedes (the horse, the ass, the zebra, &c.), as it is both safe and sure. In horses, previously prepared by two or three bran-mashes to soften the dung, the dose is from five to seven drachms. It acts slowly, requiring from eighteen to forty-eight hours for its operation. Mr. Youatt informs me that aloe is a valuable purgative for the dog, in doses of from one to three drachms, and with the addition of from one to three grains of calomel. Barbados aloe is preferred by veterinarians, as being more effective than Cape aloe, in the ratio of about seven to five. Aloe proves purgative to oxen, sheep, and pigs, but, as in the other cases, it operates slowly.⁸ Moiroud⁹ injected into the veins of a horse four drachms of aloe dissolved in water with a little alcohol, and the next day an ounce more, without any other effect than the evacuation of a large quantity of urine. The dung, however, was enveloped by a thin pellicle formed by altered intestinal mucus. This was collected and analyzed subsequent to the death of the animal (which followed three days after the injection): it offered scarcely any traces of the constituents of the bile.

γ. On Man.—Taken internally in small doses aloe acts as a tonic to the alimentary canal, assisting the digestive process, strengthening the muscular fibres, and promoting the secretions, especially that of the liver, which organ it is thought specifically to influence. In large doses it acts as a purgative. There are, however, some peculiarities attending its cathartic operation deserving of notice. In the first place, these effects are not so speedily produced as by some other purgatives; for eight, twelve, and sometimes twenty-four hours elapse before they are produced. Secondly, aloe acts especially on the large intestines, and a full dose is in some persons apt to produce heat and irritation about the rectum, and tenesmus; and, in those troubled with hemorrhoids, it is said not unfrequently to increase, or even to bring on, the sanguineous discharge. Fallopian⁰ tells us, that of one hundred persons who used aloe as a purgative, ninety were affected with the hemorrhoidal flux, which ceased when the use of aloe was omitted. But though this statement has been often quoted as an objection to the use of aloe, it is of little importance, as there is no evidence that the disease was brought on by aloe. The uterus, in

common with all the pelvic viscera, is stimulated by aloes. A determination of blood towards these organs, and a fulness of the blood-vessels (especially of the veins), are produced, and thus uterine irritation and menorrhagia are apt to be increased by aloes, while in amenorrhoea and chlorosis it may occasionally act as an emmenagogue. Dr. Wedekind\(^4\) says that small doses of aloes often occasion erection, and increase the sexual feelings.

The purgative effects of aloes do not arise merely from their local action on the alimentary canal, since this effect is sometimes produced when the medicine has been neither swallowed nor given by the rectum. Thus Monro \textit{primus}\(^3\) tells us, that the tincture of aloes applied to a caries of the bone produced purging; and it is said\(^2\) that an aloetic pill used as a stimulant to an issue had a similar effect; lastly, applied to a blistered surface it has the same operation. So that the purgative action of aloes appears to be of a specific kind.

According to Dr. Wedekind,\(^4\) the operation of aloes depends on the increased secretion of bile, which is produced by the specific action of this medicine on the liver. He founds this opinion on the results of various experiments. Thus, he says, that if aloes be added to purgatives (a laxative infusion and sulphate of soda), whose operation is speedy, its effects do not take place for some hours after those caused by the other purgatives; and he also asserts that the evacuations in the second purging differ from those of the first both in appearance and smell. Moreover, he found that, as long as the stools were white or gray in icterus, the aloes did not purge even when exhibited in large doses; but the purgative effect supervened immediately after the fecal matter began to contain bile, proving that the presence of bile in the intestinal canal is a necessary condition of the purgative effect of aloes. But in Moiroud's experiment, above quoted, no effect seemed to be produced on the hepatic secretion.

In all probability, the increased secretion of bile, the irritation about the rectum, the disposition to hemorrhoids, and the vascular excitement of the sexual organs, all of which are said to be produced by aloes, are the effects of a stimulant action exerted by this medicine over the venous system of the abdomen, and especially of the pelvis.

Dr. Greenhow\(^5\) ascribes a diuretic effect to aloes, and his statement is corroborated by Moiroud's experiment.

Socotrine aloes is said not to be so apt to occasion hemorrhoids as the Barbados kind. Some years since, Dr. Clutterbuck instituted numerous experiments at the General Dispensary, Aldersgate Street, which I witnessed, to determine the effects of the different kinds of aloes, but scarcely any difference in their operation on the human subject was perceptible. However, it is probable that Cape aloes is less powerful in its action on man, as it is on the horse, than the Barbados kind. But the difference is the less obvious in the human subject, on account of the comparative smallness of the dose required to produce the purgative effect.

As a purgative, aloes holds an intermediate rank between rhubarb and senna. Vogt\(^6\) places it between jalap and rhubarb. From rhubarb it is distinguished by its more stimulant influence over the large intestines and the pelvic organs: from senna by its febrile action as a purgative, by its slow operation, and by its tonic influence when given in small doses. It irritates less powerfully than either jalap or scammony: further, its influence over the blood-vessels of the pelvic viscera is greater than these.

\textbf{Use.—} The uses of aloes may be readily inferred from the remarks already made. It is evidently not adapted for those cases in which a speedy effect is required; and it is, therefore, useless to add it to purgatives to quicken their operation. It is well fitted for cases of costiveness where there is a scanty secretion of bile, and for

\(^1\) \textit{Rust's Magazin.} 1827, Bd. 34, Heft 2, S. 304.

torpid conditions of the large intestines, especially when attended with deficient uterine action. Some of the ill effects ascribed to the use of aloe are probably imaginary, and others are much exaggerated. It is, however, advisable to avoid the use of this purgative in inflammatory conditions and organic diseases of the liver, in biliary calculi, in mechanical impediments to the passage of the blood through the branches of the portal veins, in hemorrhage from any of the pelvic organs (as the uterus and rectum), in irritation of the rectum, prostate gland, or bladder, in pregnancy, &c. For we have many other equally efficient purgatives, to the use of which, in these cases, no ill consequences have been ascribed. While, therefore, I concur with Dr. Fothergill in advising that the exhibition of aloe should be avoided when the menses are about to cease, I am not prepared to admit that "the piles, strangury, immoderate discharges of the menses, racking pains in the loins, representing labour pains, and other similar complaints," are frequently induced by this medicine. On the contrary, I suspect this catalogue of the evils of aloeic purges to be much overcharged. "Aloetic medicines," says Dr. Denman, "are forbidden during pregnancy, lest they should do mischief by their supposed doobstruent qualities; but they are cheap, and conveniently given in the form of pills, and I have not observed any bad effects from them." The emaciation, stricture of the rectum, and enteritis, referred by Dr. Greenhow to the long-continued use of aloetic medicines, ought, doubtless, to be ascribed to other causes.

The following are some of the cases in which the use of aloe has been advised:—

1. In loss of appetite and dyspepsia, depending on a debilitated condition of the digestive organs, accompanied by costiveness, but unattended with any signs of local irritation, aloe may be given in small doses as a stomachic.

2. In habitual costiveness, depending on deficiency of bile, or on a sluggish condition of the large intestines—particularly in hypochondriacal or studious persons, or in those whose habits or occupations are sedentary—aloe, given in sufficient doses to purge, will be found a very useful medicine. A torpid state of the colon, with large fecal accumulation, is not unusual in females. In such, the use of aloe is often attended with much benefit.

3. To excite the menstrual discharge, aloe is frequently employed. It has been supposed that, by determining an afflux of blood to the pelvic organs, aloe would stimulate the uterine vessels, and thus relieve deficient menstruation connected with atonic conditions of the uterus. But it often fails: indeed, Dr. Cullen says that it rarely succeeds.

4. To reproduce the hemorrhoidal discharge, aloe has been frequently employed in large doses. Serious affections of the head, or of other parts, have sometimes disappeared on the occurrence of the hemorrhoidal flux; and, therefore, in persons who have been subject to this discharge, but in whom it has stopped, it is advisable to attempt its re-establishment, with the view of relieving other more serious disorders.

5. To promote the secretion of bile where a deficiency of this fluid does not arise from hepatic inflammation; as in some forms of jaundice which are unconnected with biliary calculi, inflammation, mechanical obstruction of the ducts, &c.

6. In cerebral affections.—The compound decoction of aloe is a most valuable stimulating purgative for elderly persons in whom a tendency to apoplexy exists, especially in cold and phlegmatic habits. It will frequently be necessary to conjoin other cathartics, as the infusion of senna.

7. As an anthelmintic, a decoction of aloe, used as an enema, has been efficacious in the small thread-worm (Ascaris vermicularis).

Administration.—On account of its nauseous taste, aloe is frequently given in the form of pill (pilula aloetice, offic.). One or two grains seldom fail to pro-

5 Intro, to the Pract. of Midwifery.
6 Treat. of the Mat. Med.
due one stool, which seems to be merely an evacuation of what may be supposed to have been present for the time in the great intestines (Cullen). The ordinary dose is five grains; but ten, fifteen, or even twenty grains are sometimes given.

1. PILULA ALOES COMPOSITA, L. D.; Pilulæ Aloes, E.; Compound Pills of Aloes.—(Socotrime Aloes [Hepatic, D.], powdered, $\frac{3}{5} j$; Extract of Gentian $\frac{3}{5} s$; Oil of Caraway $\text{m} x l$. $\frac{5}{5} s$, D.); Treacle, as much as may be sufficient [5j; D.].—Beat them together until incorporated. The Edinburgh College orders of Socotrime Aloes and Castile Soap equal parts; Conserve of Red Roses a sufficiency; beat them into a proper pill mass. This pill may be also correctly made with the finer qualities of East Indian Aloes, as the Socotrime variety is very scarce; and many, not without reason, prefer the stronger Barbados Aloes, E.—This pill is a valuable purgative in habitual costiveness. Dose, five to fifteen grains.

2. PILULA ALOES CUM MYRRHÀ, L. D.; Pilulæ Aloes et Myrrhæ, E. [U. S.]; Pilulæ Rufi, offic.; Pills of Aloes and Myrrh; Rufus's Pills.—(Socotrime or Hepatic Aloes $\frac{3}{5} s$ [four parts, E.]; Saffron $\frac{5}{5} j$ [one part, E.]; Myrrh $\frac{5}{5} j$ [two parts, E.]; Soft Soap $\frac{5}{5} j$; Treacle [Conserve of Red Roses, E.], as much as may be sufficient. Rub the aloes and the myrrh separately to powder; then beat the whole together until incorporated [Aloes $\frac{5}{5} j$; Myrrh $\frac{5}{5} j$; Saffron $\frac{3}{5} s$; Syrup q. s. M. To be divided into 480 pills, U. S.].—Used as a purgative in chlorosis and amenorrhea. Dose, ten to twenty grains.

3. PILULA ALOES CUM SAPONE, L.; Pilulæ Aloes Diluta; Pills of Aloes and Soap.—(Extract of Barbados Aloes powdered, Soft Soap, Extract of Liquorice, equal parts; Treacle as much as may be sufficient. Beat the aloes with the soap; then, having added the others, beat the whole together until incorporated.)—Dose, grs. v to grs. x.

4. PILULE ALOES ET ASSAFETIDÆ, E. [U. S.]; Pills of Aloes and Assafetida.—(Aloes [Socotrime or East Indian], Assafetida, and Castile Soap, equal parts. Beat them, with Conserve of Red Roses, into a proper pill mass.)—Used in dyspepsia attended with flatulence and costiveness. Dose, ten to twenty grains.

5. PILULE ALOES ET FERRI, E.; Pills of Aloes and Iron.—(Sulphate of Iron three parts; Barbados Aloes two parts; Aromatic Powder six parts; Conserve of Red Roses eight parts. Pulverize the aloes and sulphate of iron separately; mix the whole ingredients, and beat them into a proper mass, which is to be divided into five-grain pills.)—A valuable emmenagogue in atonic amenorrhœa and chlorosis. Dose, one to three pills.

6. PULVIS ALOES COMPOSITUS, L.; Compound Powder of Aloes.—(Socotrime or Hepatic Aloes $\frac{3}{5} s$; Guaiacum Resin $\frac{5}{5} j$; Compound Powder of Cinnamon $\frac{3}{5} s$. Rub the aloes and the guaiacum resin, separately, to powder; then mix them with the compound powder of cinnamon.)—Purgative and sudorific. Seldom used. Dose, ten to twenty grains.

7. PULVIS ALOES CUM CANELLÀ [U. S.]; Hiera Picra, offic.; Powder of Aloes and Canella.—(Hepatic Aloes $\frac{1}{5} j$; Canella bark $\frac{5}{5} j$. Powder them separately, and then mix.)—A popular emmenagogue. Dose, five to fifteen grains.

8. DECOCTUM ALOES COMPOSITUM, L. D.; Decocutum Aloes, E.; Compound Decoc- tion of Aloes.—(Extract of Liquorice $\frac{5}{5} j$ [5s, E. D.]; Carbonate of Potash $\frac{5}{5} j$ [5j, E. D.]; Extract of Socotrime Aloes [Hepatic, D., or Socotrime, E.] powdered, Myrrh powdered, Saffron, of each $\frac{3}{5} s$ [5j, E. D.].) Compound Tincture of Cardamom $\frac{5}{5} j$ [5j, E., as much as is sufficient, D.]; Distilled Water Oiss [5j, E., $\frac{5}{5} j$, D.]. Boil down the liquorice, carbonate of potash, aloes, myrrh, and saffron, with the water, to a pint [5j, E.], and strain; then add the compound tincture of cardamom [as much as will make sixteen fluidounces, D.].—A most valuable preparation. A mild cathartic, tonic, antaedic, and emmenagogue. Used
VEGETABLES.—NAT. ORD. LILIACEAE.

in the before-mentioned cases in doses of f3ss to f3ii. Acids, acidulous salts, and most metallic salts, are incompatible with it. If it be desirable to conjoin chalybeates with it, either the Potasse Ferrico-Tartras (see vol. i. p. 752) or the Ammoniae Ferrico-Citras (see vol. i. p. 749) may be added to the cold decoction without undergoing decomposition. The quality of the aloe used, the length of time the decoction is boiled, and the purity of the extract of liquorice, affect the transparency or turbidity of this decoction, which is never so bright as tinture of aloe.²

9. EXTRACTUM ALOES, L.; Extractum Aloes Purificatum; Purified Extract of Aloes.—(Socotrinite Aloes ^ixv; Boiling Water Cong. j. Macerate for three days with a gentle heat; afterwards strain and set by, that the dregs may subside. Pour off the clear liquor, and evaporate it to a proper consistence.—It is intended to deprive the aloe of the substance called resin, on which its irritating and griping qualities have been supposed to depend. Dose, five to fifteen grains.

3. EXTRACTUM ALOES BARBADENSIS, L.; Extract of Barbados Aloes.—This is prepared in the same way as the Extractum Aloes, L.

4. EXTRACTUM ALOES HEPATICÆ; Extractum Aloes Aquosum, D.; Extract of Hepatic Aloes; Watery Extract of Aloes.—Hepatic Aloes, in coarse powder, ^iv; Water Oij. Boil the aloe until it is dissolved; when the solution is cold, and the dregs have subsided, pour off the clear liquid, and evaporate it to a proper consistence, D.

The effects, uses, and doses of these two preparations are the same as those of Extractum Aloes.

10. TINCTURA ALOES, L. E. [U. S.]; Tincture of Aloes.—(Socotrinite or Hepatic Aloes, coarsely powdered, ^ij; Extract of Liquorice ^iji; Distilled Water Ois [Oj and ^ivii; E.]; Rectified Spirit Oii [^ixij, E.]. Macerate for seven [with occasional agitation, E.] days, and strain. This tincture cannot without difficulty and delay be prepared by percolation, E.)—Purgative and stomachic. Dose, ^j to ^j.

11. TINCTURA ALOES COMPOSITA, L.; Tinctura Aloes et Myrrhae, E. [U. S.]; Elixir Proprietas of Paracelsus, Compound Tincture of Aloes.—(Socotrinite or Hepatic Aloes, coarsely powdered, ^iv [^iij, U. S.]; Saffron ^iij [^ii, U. S.]; Tincture of Myrrh Oij. Macerate for seven days, and strain, L. This tincture cannot be well prepared by percolation, E.)—Purgative, stomachic, emmenagogue. Used in cold, sluggish habits. Dose, ^ss to ^j.

12. VINUM ALOES, L. E. [U. S.]; Tinctura Sacra; Wine of Aloes.—(Socotrinite or Hepatic Aloes, rubbed to powder, ^ijj; Canella, powdered, ^iv; Sherry Wine Oij. Macerate for seven days, frequently shaking, and strain. The Edinburgh College uses Aloes [Socotrinite or East Indian] ^iss; Cardamom seeds ground, Ginger in coarse powder, of each ^iss; Sherry Oij. Digest for seven days, and strain through linen or calico [Aloes, in powder, ^i; Cardamom bruised, Ginger bruised, of each a draehm; White Wine a pint. Macerate for fourteen days, with occasional agitation, and filter through paper, U. S.].—Wine of aloes is purgative in doses of f3ss to f3iij; stomachic in doses of f3^i to f3^ij.

Aloes is a constituent of several other preparations (as Pilula Colocynthidis composita, L. D.; Pilula Colocynthidis, E.; Pilulae Rhei compositae, L. E.; Pilulae Cambojiae, E.; Pilulae Cambojiae compositae, L.; Tinctura Rhei et Aloes, E.), which will be described hereafter.

62. URGINEA SCILLA, Steinheil.—THE SEA ONION, OR OFFICINAL SQUILL.

Sex. Syst. Alexandria, Monogynia.
(Bulbus recens, L.—Bulb, Z. D.)

SYNONYMES.—*Squilla maritima*, Steinheil;¹ *Scilla maritima*, Linn.; *Cepa marina*, Lobel.

HISTORY.—The Egyptians worshipped a bulbous plant called by Lucian Κρόομυνον; and which Pauw² asserts to be the squill, and further suggests that it was the red variety (? *Squilla Puncture* var. *& Bulbo rafos*, Steinheil); but by others it is has been thought to be the onion (see *Allium Cepa*). Pythagoras³ is said to have written a volume on the medicinal properties of squill, and to have invented the *acetum scillae*. Hippocrates employer squill (*σκίλλα*) internally,⁴ externally,⁵ and as a pessary.⁶ Pliny⁷ says there are two medicinal sorts of squills—one, which he calls the *male*, with white leaves; the other, or *female*, with black leaves: the former probably is white, the latter red squills.

BOTANY. Gen. Char.—Sepals three, coloured, spreading. Petals very like them, and scarce broader. Stamens six, shorter than the perianth; filaments smooth, somewhat dilated at the base, acuminate, entire. Ovary three-parted, glandular and mellowiferous at the apex; style smooth, simple; stigma obscurely three-lobed, papillose. Capsule rounded, three-cornered, three-celled. Seeds numerous, in two rows, flattened with a membranous testa. (Steinheil.)

Sp. Char.—Leaves very large, subsequently spreading. Bracts long. Flowers white; flower-bud somewhat acute. Anthers yellow. Ovarium thick, yellowish. Bulb very large. (Steinheil.)

Bulb roundish-ovate, half above ground. The leaves appear after the flowers: they are broad, lanceolate, twelve to eighteen inches long. Scope about two feet high, terminated by a dense long raceme.

Hab.—Shores of the Mediterranean, viz.: Spain, France, Sicily, Africa, &c. Navarino has long been celebrated for its squills. In its native soil the plant flowers about August.

*Squilla Pancration*, Steinb. (Παντρακίον, Dioscorides) is said by Steinheil to yield a small bulb of a reddish colour, found in commerce under the name of squill.

DESCRIPTION.—The fresh bulb (*bulbus recens*, L.; *radix recens*, offic.) is pyriform, of the size of the fist to that of a child's head, and is composed of thick, fleshy, smooth, shiny scales, attenuated at their edges, closely applied over each other, and attached to a conical disk (a rudimentary stem) which projects inferiorly, and gives origin to the root fibres, the remains of which are to be frequently found in the bulbs of commerce. The outer scales are usually dry, thin, coloured, membranous, or papery. By cracking the inner or fleshy scales, numerous spiral vessels may be drawn out. On submitting the cuticle of the scales to a microscopic examination, numerous acicular crystals (*raphides*) are perceived in cells, which are distinguished from the surrounding angular cells by being larger and elliptical. The *pulvis scillae*, offic., contains nine or ten per cent. of these crystals.

Two kinds of squills, both abounding in an acrid juice, and having a very bitter taste, are met with in commerce; viz., the *white* (*squilla alba*, mascula, vel hispa-

¹ In 1834, Steinheil (Ann. Sc. Nat. t. i. p. 261, 2nd Sér.) proposed the name *Urginea* for the genus to which squill (*Urginea Scilla*, Steinb.) belongs. Some objections having been raised to it, and no systematic writer having then adopted it, Steinheil, in 1836 (op. cit. t. vi. p. 372), proposed to substitute the name of *Squilla* (*σκίλλα*) for *Urginea*; but subsequently some writers have adopted the term *Urginea* as the generic name.

² *Phil. Diss. on the Egyptians and Chinese*, vol. i. p. 120, 1765.

⁴ De *viciis ratione.*

⁶ *De nat. Mix.*
VEGETABLES.—Nat. Ord. Liliaceae.

4. Acrid, volatile? matter.—It is well known that squill, in the recent state, is very acrid, and, when applied to the skin, causes irritation, inflammation, and even vesication. By drying, the greater part of this acridity is got rid of; and hence the acrid principle is usually described as being of a volatile nature, and, in confirmation of its volatility, Athanasius states that two ounces of water distilled from fresh squills caused the death of a dog in six hours. However, by others, its volatility is denied; and Vogel says, that six ounces of water distilled from fresh squills had no effect on dogs. Buchner states, that besides the bitter scillitin, squill contains, according to his experiments, another principle, which is combined with phosphate of lime, and which is capable of exciting itching and inflammation. This acrid matter may be easily decomposed, but is not volatile, as is generally supposed.

2. Scillitin (Scillitia, Thomson).—The substance to which Vogel gave the name of Scillitin is a whitish transparent deliquescent substance, which, when dry, has a resinous fracture, and may be easily rubbed to powder. Its taste is bitter, and subsequently sweetish. It readily dissolves in water, spirit of wine, and acetic acid. The substance sold in the shops under the name of Scillitin is a thick treacle-like liquid. Landereich obtained crystals of Scillitin. He says they possessed alkaline properties. Leborcia on the other hand, says it is neutral and incrystallizable. It obviously requires further examination.

3. Rapidus (Phosphate of lime? Oxalate of lime?).—The acicular crystals found in the cuticle of the scales of the bulb, as before mentioned, probably consist of phosphate of lime, or, according to Schleiden, of oxalate of lime. These, perhaps, are the needle-like crystals obtained by Vogel by evaporating the juice of the bulb, and which he regarded as citrate of lime. According to the late Mr. E. Quekett they constitute about 10 per cent. of powdered squills.

Chemical Characteristics.—An aqueous decoction of squills is pale, and very bitter. Sesquichloride of iron communicates an intense purplish blue colour (gallate of iron) to it. (This test I have not found to succeed uniformly. The decoction of some specimens of squills scarcely becomes altered by the salts of iron.) Gelatin has scarcely any effect on it. Nitrate of silver forms a white precipitate (chloride of silver) soluble in ammonia, but insoluble in nitric acid. Oxalate of ammonia renders the decoction turbid, and after some time causes a white precipitate (oxalate of lime). Diacetate of lead and proto-nitrate of mercury form pre-

Physiological Effects.

209

cipitates in the decoction. Tincture of nutgalls has little or no effect on it; it sometimes occasions a cloudiness. Starch is not recognizable in it by iodine. Alkalis heighten the colour of the decoction.

An infusion of squills in water acidulated with hydrochloric acid yields a white precipitate with oxalate of ammonia (oxalate of lime); and with caustic ammonia sometimes a precipitate (phosphate of lime), at others scarcely a cloud.

Physiological Effects. 1. On Vegetables.—Not ascertained.

2. On Animals.—An ounce of powdered squills acts as a diuretic on horses and other large animals; the same effect is produced on smaller animals by half a drachm. When the dose is large, squill acts as a poison. It first causes local irritation; then its active principle becomes absorbed, affects the nervous system, and thereby quickens the respiration, causes convulsions, and death. Hillefeld mentions paralysis produced in a rabbit by nineteen grains of powdered squill. Emmert and Hoering state that the squill juice introduced into the abdominal cavity became absorbed.

γ. On Man.—Squill is an acrid. In small doses it acts as a stimulant to the excretory organs. Thus it promotes secretion from the mucous membranes (especially the bronchial and gastro-intestinal) and the kidneys. Its most marked effect is that of a diuretic. Its expectorant effects are less obvious and constant. Sometimes, when it fails to act on the kidneys, it increases cutaneous exhalation. Its influence on secreting organs is probably to be referred to the local stimulus communicated to their vessels by the active principle of squill in its passage out of the system, for Emmert and Hoering have shown that the juice is absorbed, so that squills may be regarded as an acrid even for these remote parts. When it proves diuretic in dropsies, it usually promotes the absorption of the effused fluid—an effect which is, I think, indirect, and a consequence of the diuresis. But Sundelin observes that squill, that it promotes the secretion of urine less by its local irritation of the kidneys, than by its general excitement of the absorbent apparatus.

By the continued use of squill, in gradually increased doses, it disturbs the functions of digestion and assimilation.

In full medicinal doses, squill excites nausea and vomiting. Purging, also, is not unfrequently produced. When squill proves emetic or purgative, its diuretic operation is much less obvious—a circumstance which Cullen refers to the squill being prevented reaching the blood-vessels and kidneys. Home, however, alleges that the diuretic effects are not to be expected unless there be some operation on the stomach. But the operation on the stomach may be, as Cullen suggests, a mere test of the activity of the squills. However, that the effect of squill, in strong doses, is not confined to the alimentary canal, is proved by the fact, that when the vomiting and purging were present, the pulse has been observed to be reduced in frequency, often to forty beats per minute (Home).

In excessive doses, squill acts as a narcotico-acrid poison, and causes vomiting, purging, griping pain, strangury, bloody urine, convulsions, inflammation, and gangrene of the stomach and intestines. Twenty-four grains of the powder have proved fatal.

Considered with reference to its diuretic effect, squill is comparable with foxglove. But it exceeds the latter in its stimulant influence over the urinary organs. On the other hand, foxglove is characterized by its powerfully sedative effect on the vascular system; for though squill has, in some instances, reduced the frequency of the pulse, this effect is by no means common. Squill, says Vogt, preponderates in its action on the inferior or vegetative [organic] life; foxglove, on the other hand, in its action on the higher or animal life.

1. Moiroud, Pharm. Vétér.
USING.—The principal uses of squill are those of an emetic, diuretic, and expectorant.

1. As a diuretic in dropsies.—It is applicable to those cases of dropsy requiring the use of stimulating or acrid diuretics, and is improper in inflammatory cases. It is an unfit remedy for dropsy complicated with granular kidney or vesical irritation; but when these conditions are not present, it is adapted for torpid phlegmatic subjects. Hence, it is more serviceable in anasarca than in either ascites or hydrothorax. It should be given so as to excite a slight degree of nausea (not vomiting), as recommended by Van Swieten. By this means its absorption is promoted. The acetate or bitartrate of potash may be conjoined. Calomel is usually regarded as a good adjunct for promoting the diuretic influence of squill. When it does not purge it is beneficial, but its tendency to affect the bowels is an objection to its use.

2. As an expectorant in chronic pulmonary affections admitting of the use of a substance stimulating the capillary vessels of the bronchial membrane. Thus, in chronic catarrh, humid asthma, and winter cough, it is often employed with considerable benefit. It is of course improper in all acute cases accompanied with inflammation or febrile disorder. In old persons it is often combined with the tinctura camphorae composita, and with good effect. The oxymel or syrup of squill may be given to relieve troublesome chronic coughs in children.

3. As an emetic, it is occasionally used in affections of the organs of respiration requiring or admitting of the use of vomits. Thus, the oxymel is given, with the view of creating sickness and promoting expectoration, to children affected with hooping-cough; and sometimes, though with less propriety, in mild cases of croup. The great objection to its use is the uncertainty of its operation: in one case it will hardly excite nausea, in another it causes violent vomiting. Furthermore, it is of course highly objectionable as an emetic for delicate children with irritable stomachs, on account of its acrid properties, and the irritation it is capable, in these cases, of setting up.

ADMINISTRATION.—The following are the preparations of squills usually employed:

1. PULVIS SCILLÆ; Powder of Squill.—The bulb loses about four-fifths of its weight by drying; so that six grains of the dry powder are equal to half a drachm when fresh. Powdered squill readily attracts water from the atmosphere, and becomes soft and mouldy; hence the necessity of preserving it in stoppered bottles and in a dry place. I have seen it become hard and massive like diachylon plaster. It is usually administered in the form of pill. The dose of the powder, as an emetic, is from six to fifteen grains; ten grains being the average. As an expectorant or diuretic we should commence with one grain, and gradually increase the dose until slight nausea is excited.

2. PILULA SCILLÆ COMPOSITÆ, L.; Pilulae Scillæ Compositæ, D. [U. S. ]; Pilulae Scillæ, E.; Compound Squill Pill.—(Squill, fresh dried and powdered, 5i; [5iiss, D.]; Ginger powdered, Ammoniacum powdered, of each 5i; Soft Soap 5i (Castile Soap 5i, D.) [Syrup, U. S.]; Treacle as much as may be sufficient [by weight 5iss, D.]. Mix the powders together; then beat them with the other ingredients until they are incorporated. The Edinburgh College takes of powdered Squill five parts; powdered Ammoniac, Ginger, and Spanish Soap, of each four parts; Conserve of Red Roses two parts; and forms them into five-grain pills.)—Expectorant and diuretic. Principally used in chronic bronchial affections. Dose, from five to twenty grains. It readily spoils by keeping.

3. TINCTURA SCILLÆ, L. D. E. [U. S. ]; Tincture of Squills.—(Squill, fresh dried [in coarse powder, E.], 3v; Proof Spirit Oij; macerate for seven [fourteen, D.] days, and strain, L. Prepare this tincture by percolation, as directed for

1 Commentary upon Boerhaave's Aphorisms, vol. xii. p. 435.
tincture of cinchona, but without packing the pulp firmly in the percolator. It may likewise be obtained by the process of digestion from the sliced bulb." E.) [The U. S. Pharm. directs of Squill four ounces; diluted Alcohol two pints; macerate for fourteen days, compress and filter through paper; or, this tincture may also be prepared by thoroughly moistening the Squill in powder, with diluted Alcohol, allowing it to stand for twenty-four hours, then transferring to an apparatus for displacement, and gradually pouring upon it diluted Alcohol, until two pints of the filtered liquor are obtained.—Expectorant and diuretic. Used in chronic bronchial affections. Dose, m x to fʒs.

4. ACETUM SCILLE, L. D. E. [U. S.]; Vinegar of Squills.-(Squill, fresh dried and powdered, ʒiij, D.]; Dilute Acetic Acid Oj [Acetiac Acid of commerce (sp. gr. 1.044), ʃʒ; Distilled Water ʒxiij, D.]; [Proof Spirit ʃʒiij, L.]. The ingredients and relative proportions used by the Edinburgh College are the same as those of the London College, except that distilled vinegar is employed. Macerate the squill with the vinegar, with a gentle heat, in a covered vessel, for three [seven, D. Ed.] days; afterwards press out [the liquor] and set it aside, that the dregs may subside; lastly, add the spirit to the clear liquor. [The U. S. Pharm. directs, of Squill, bruised, four ounces; Diluted Acetic Acid two pints; Alcohol a fluidounce. The process is the same as that of the Dublin College; or it may be made by displacement.]—Expectorant and diuretic. Used in chronic pulmonary affections and dropsies, under the regulations before described. Dose, ʒiij to ʒiij, in some aromatic water.

5. OXYMEL SCILLE, L. [U. S.]; Syrupus Scille, E.; Oxyrnel of Squills; Syrup of Squills.—(Honey ḫb; Vinegar of Squill Ɋiij. Boil down the vinegar, with a slow fire, to twelve fluidounces, and mix the honey, made hot, L.—Vinegar of Squills Oij; Pure Sugar ḫbįj. Dissolve the sugar in the vinegar of squills with the aid of a gentle heat and agitation, E.) [Vinegar of Squill Oj; Clarified Honey Oiij. Mix them, and evaporate, by means of a water-bath, to the proper consistence. The specific gravity should be 1.32, U. S.)]—Used as an expectorant in chronic catarrhs and asthma, in doses of ḫj or ʃj. As an emetic, it is sometimes given to children affected with hooping-cough or croup, in doses of a teaspoonful repeated every quarter of an hour until vomiting occurs.

6. SYRUPUS SCILLE, U. S.; Syrup of Squills.—This is directed to be prepared of Vinegar of Squills a pint; Sugar two pounds. Add the sugar to the vinegar of squill, and proceed in the manner directed for syrup. This preparation is used in place of the preceding as an emetic and expectorant. In affections of the lungs, where squill is beneficial, it may be employed as an ingredient of cough mixtures, variously compounded. As a common remedy for children in cases of cough or cold, it is with safety directed and commonly used. The dose is ʃʒs to ʃʒ or ʃj.

7. SYRUPUS SCILLE COMPOSITUS, U. S.; Compound Syrup of Squill; Hive Syrup.—Take of Squill bruised, Senega bruised, each four ounces; Tartrate of Antimony and Potassa forty-eight grains; Water four pints; Sugar three pounds and a half. Pour the water upon the squill and senega, and having boiled to one-half, strain, and add the sugar; then evaporate to three pints, and, while the syrup is still hot, dissolve in it the tartrate of antimony and potassa. Another mode of preparation is, to take of Squill in coarse powder, Senega in coarse powder, each four ounces; Tartrate of Antimony and Potassa forty-eight grains; Alcohol half a pint; Water a sufficient quantity; Sugar three pounds and a half. Mix the alcohol with two pints and a half of water, and macerate the squill and senega in the mixture for twenty-four hours. Put the whole in an apparatus for displacement, and add as much water as may be necessary to make the filtered liquor amount to three pints. Boil the liquor for a few minutes, evaporate to one-half, and strain; then add the sugar, and evaporate until the resulting syrup measures three pints. Lastly, dissolve the tartrate of antimony and potassa in the syrup, while it is still hot.

This preparation is a modification of that made according to the formula given.
by Dr. J. R. Coxe, and which goes by the name of Coxe’s Hive Syrup. In the former editions of the Pharmacopoeia, the formula of Dr. Coxe was adopted; and as honey was substituted for sugar, it had the official name of *Mel Scillae composition.* The formula above cited authorizes the substitution of sugar for honey, as it is less liable, when prepared as directed, to undergo fermentation—a great desideratum in hot weather. There is no difference between the proportions of the ingredients, so that an equal strength of the two preparations is obtained by both. The latter was introduced in accordance with the recommendation of the Committee of Revision of the Philadelphia College of Pharmacy.

This preparation combines the advantages of squill, senega, and tartarized antimony, and is an exceedingly active preparation. In sufficient doses, it operates upon the stomach, producing free vomiting and expectoration. It is used at the commencement of croup, hooping-cough, and catarrhal affections in children, with the view to its evacuant impression. In the inflammatory stages, as an expectorant and nauseant, it may also be employed with advantage, in reduced doses. The dose is from gtt. x to f51, according to the age of the child, repeated every ten or fifteen minutes until it pukes. As an expectorant for adults, the dose is gtt. xx to gtt. xxx.

**Antidote.**—No antidote is known. The first object, therefore, in a case of poisoning, is to evacuate the stomach; the second, to allay the inflammatory symptoms which may supervene.

---

**63. ALLIUM SATIVUM, Linn.—Common or Cultivated Garlic.**

*Sex. Syst. Hexandria, Monogynia.*

**(Bulb, E.)**

**History.**—This plant was well known to the ancients. The Greeks called it *oxóßov;* the Romans *Allium.* It was used by Hippocrates.

**Botany.**

**General Char.**—Flowers umbellate, with a membranous spathe. **Perianth** six-parted, permanent, equal. **Stamens** inserted into the base of the perianth; **filaments** either all alike, or every other one tricuspidate, with the **anther** on the middle point. **Style** subulate, **stigma** simple. **Capsule** usually obtusely three-cornered or three-lobed, depressed, three-celled, bursting into three valves through the dissepiments, and containing two or one black angular seed in each cell.

*(Lindley.)*

**Specific Char.**—Bulb surrounded by smaller ones. **Leaves** linear, entire. **Umbel** bulbiferous, globose. **Spatha** ovate, rounded. **Segments** of the perianth ovate, obtuse. **Pistil** and **stamens** exsert. **Stem** about two feet high. **Flowers** whitish.

**Description.**—The bulb (*bulbus allii*) is composed of *clove* (*spicium vel nuclei allii*), each furnished with its proper envelopes. Its odour is strong, irritating, and characteristic; its taste is acrid.

**Composition.**—Cadet analyzed garlic. He found the constituents to be *acrid volatile oil,* *extractive* (a little), *gum, woody fibre, albumen,* and *water.* The ashes contained alkaline and earthy salts. Bouillon-Lagrange has detected, besides these, *sulphur,* *starch,* and *saccharine matter.*

**Oil of Garlic (Oleum Allii)** is a sulphuret of allyle, **AII=CH**2=S (see vol. i. p. 233). According to Wertheim, an oxide of allyle, **AIIO=CH**2=O, also exists in the crude oil. Oil of garlic has a very acrid taste, a strong smell, and a yellow colour. It is heavier than water, and is soluble in alcohol. As it contains sulphur it produces, in burning, sulphurous acid. According to Cadet, 20 lbs. of garlic yielded only six drachms of essential oil; Wertheim obtained between

---

three and four ounces from 1 cwt. of garlic. It strikes a black colour when rubbed with oxide of iron. It is a powerful irritant, and when applied to the skin causes irritation. The Hindoos, according to Dr. Ainslie, prepare a stimulating expressed oil from garlic, which they give internally inague, and use externally in palsy and rheumatism.

Physiological Effects.—Garlic is a local irritant. When swallowed, it operates as a tonic and stimulant to the stomach. Its volatile oil becomes absorbed, quickens the circulation, occasions thirst, and is thrown out of the system by the different excretories, the activity of which it promotes, and to whose excretions it communicates its well-known odour. Large doses occasion nausea, vomiting, and purging. Pullen\(^6\) says the expressed juice has proved fatal.

Uses.—Employed by the cook as a flavouring ingredient in various made-dishes, sauces, &c. Rarely used by the medical practitioner. Internally, it has been exhibited as a stimulant and stomachic in enfeebled digestion; as an expectorant in old chronic catarrhs; as a diuretic in atonic dropsies; and as an anthelmintic. Externally, it has been employed as a resolvent in indolent tumours; as a local irritant or rubefacient applied to the feet to cause revulsion from the head or chest; as an anti-spasmodic liniment (composed of oil and garlic juice) in infantile convulsions; as a remedy for some cases of deafness, a clove or a few drops of the juice being introduced into the ear.

Administration.—A clove may be swallowed either entire, or, more conveniently, cut into small pieces. The dose of the fresh bulbs is one or two drachms. The expressed juice mixed with sugar, the infusion of garlic, and a syrup, are sometimes employed.

[Syrupus Allii.—Take of fresh Garlic, sliced, six ounces; diluted Acetic Acid a pint; Sugar two pounds. Macerate the garlic in the diluted acetic acid in a glass vessel for four days, then express the liquor, and set it by that the dregs may subside. Add the sugar to the clear liquor, and proceed in the manner directed for syrup.

This formula was adopted upon the recommendation of Mr. Daniel B. Smith, of Philadelphia, who demonstrated the futility of the old method of preparing syrup of garlic, of which formula (Journal of Philadelphia College of Pharmacy, No. 1, p. 50) it is a modification. Dose, 3i.]

64. Allium cepa, Linn.—The Onion.

Sax. Syst. Hexandria, Monogynia.

(Bulbus.)

History.—The onion was known and used in the most ancient times. By Fraas\(^4\) it is considered to be the χρόμυυς (see ante, p. 207) of Theophrastus\(^5\) and Dioscorides.\(^6\) The στάνων of Theophrastus was a variety of onion. By Pliny\(^8\) the onion is called cepa. It was employed in medicine by Hippocrates. An onion taken from the hand of an Egyptian mummy perhaps 2000 years old has been made to grow,\(^9\)

Sp. Char.—Stem fistulous, ventricose beneath; longer than the terete, fistulous leaves. Umbel capsuliferous, globose. Segments of perianth linear-elliptic, obtuse; shorter than the stamens and pistil.\(^6\) Biennial. Flowers white. July.

Loudon\(^4\) enumerates eighteen varieties deserving of culture.

Hab.—Egypt. Cultivated in kitchen gardens.

Besides A. sativum and A. Cepa, various other species of Allium are also cultivated for culinary purposes; as, A. Porrum, the Leek; A. ascalonicum, the Shallot; A. Schemorphym, the Chive; and A. Scorodoprunum or Rocambole. Their virtues are analogous to those of the onion and garlic.

\(^4\) Materia Indica, i. 131.
\(^6\) Lib. ii. cap. 181.
\(^7\) Mueller's Physiol. by Baly, vol. i. p. 29.
\(^8\) Encyclopedia of Gardening.
\(^9\) Quoted by Wibmer, Die Wirk. d. Arzneim.
VEGETABLES.—NAT. ORD. LILIACEÆ.

Description.—The bulb (bulbus) is tunicated. When cut, it evolves an acid principle, having a well-known odour, and a powerful action on the eyes, causing a flow of tears. Its taste is sweet and acid. Onion juice is colourless, but by exposure to the air it becomes reddish.

Composition.—According to Foureroy and Vauquelin, the onion contains an acid volatile oil, uncrystallizable sugar, gum, woody fibre, albumen, acetic and phosphoric acids, phosphate and citrate of lime, and water.

Oil of Onions (Oleum cepae) contains sulphur, and is probably similar in composition to oil of garlic, AlIS=OH₂S. It is acid, piquant, and colourless.

Physiological Effects.—Analogous to those of garlic, but milder. The oil becomes absorbed, and communicates the well-known onion odour to the breath. By boiling onions the volatile oil is dissipated, and the bulb is deprived of its irritating qualities, and becomes a mild esculent substance.

Uses.—Extensively used as an article of food and as a condiment. It is very rarely employed in medicine, but is adapted to the same cases as garlic. Raw onions are occasionally taken as an expectorant, with advantage, by elderly persons affected with winter cough.

Administration.—A roasted onion is sometimes employed as an emollient poultice to suppurating tumours, or to the ear to relieve ear-ache. The expressed juice has been given to children, mixed with sugar, as an expectorant.

Sex. Syst. Alexandria, Monogynia.

(Turiones et Radix.)

A well-known indigenous culinary vegetable, which is extensively cultivated in gardens for its young succulent shoots (turiones asparagi), which, when boiled, form a much admired article of food. These, as well as the root (radix asparagi), have been used in medicine.

The shoots have been chemically examined by Robiquet, who found in their juice asparagin, mannite, peculiar aqueous extractive, green acid oleo-resinous matter, wax, gluten, albumen, colouring matter, and salts of potash and lime.

Dulong analyzed the root, and found in it albumen, gum, a peculiar matter (precipitable by basic acetate of lead and protonitrate of mercury), resin, succarine matter (reddened by oil of vitriol), and salts of potash and lime. He detected neither asparagus nor mannite.

Asparagus (also called asparagus, althaein, and agédöil) crystallizes in right rhombic prisms, whose formula is C₆H₁₃NO₄·2HO. When heated to 248° F, they lose 12 per cent. of water. They have a cooling, somewhat nauseous taste, are slightly soluble in cold water, more so in boiling water, but are insoluble in alcohol and ether. By the action of acids and alkalis aided by heat asparagus is resolved into aspartic acid, C₆H₁₂N₂O₂, and ammonia, NH₃. Asparagus is found in the urine of those who have swallowed it (see ante, p. 270).

The young shoots act as diuretics, and communicate a peculiar fetid odour to the urine. This is produced neither by the asparagus nor by the volatile matter contained in the distilled water of the shoots, but by something which resides in the aqueous extract. Formerly, an emmenagogue and aphrodisiac property was ascribed to asparagus.

The medicinal properties of the root are similar to those of the shoots. Like the latter, it communicates an unpleasant odour to the urine. It formed one of the five greater aperient roots (radices quinque aperientes majores) which were formerly used in visceral diseases. The other four were butcher's broom (Ruscus aculeatus), celery or smallage (Apium graveolens), parsley (Petroselinum sativum), and fennel (Foeniculum officinale).

Though no longer contained in our Pharmacopœia, asparagus is still occasionally used as a popular remedy, chiefly as a diuretic in dropsies, and as a lithic. For these purposes the shoots are boiled and used at table; or the root, which is considered superior to the shoots, is taken in the form of an infusion or decoction (prepared by boiling an ounce of the root in a quart of water), which may be taken as a common drink.

3 Journ. de Pharm. t. xii. p. 276, 1826.
4 Mr. C. Brooke, Pharm. Journ. vol. vi. p. 560, 1847.
5 Murray (App. Med. vol. v. p. 184, 1790) thinks the odour not dissimilar to that of Geranium robertianum.
6 Plessis et Henry fils, in Journ. de Pharm. xvi. 723, 1830.
7 For some experiments on the solvent power of asparagus-juice for urinary calculi, see Lobb's Treatise on Dissolvents of the Stone, 1739.
66. Polygonatum vulgare, Def.—Solomon’s Seal.

Sex. Syst. Hexandria, Monogynia.
(Rhizoma.)

Convallaria Polygonatum, Linn.—A well-known indigenous plant, whose rhizome (radix polygonati), though long banished from the Pharmacopoeia, is still kept in the herb shops, and sold as Solomon’s Seal (Sigillum Salomonis). I suspect that the rhizome of _P. multiforum_ is also sold under the same name. When neither species is to be obtained, bryony root is commonly substituted.

Solomon’s seal is a white, fleshy, odourless rhizome, having a sweetish, mucilaginous, very slightly bitterish, acrid taste. Iodine applied to the fresh cut surface of the rhizome gathered in September does not darken it. In these properties, the rhizomes of both the above-mentioned species of Polygonatum agree. Walz examined chemically the herb, stem, and root of _P. multiforum_. He found in them asparagin, uncrystallized sugar, starch, gum, gluten, peculiar nitrogenous matter, acrid resin, pectin, malic, citric, hydrochloric, and phosphoric acids, potash, magnesia, lime, and alumina.

Solomon’s seal is a popular application to bruised parts (the eye, for example), to remove the marks. For this purpose it is scraped and applied to the parts. Gerard says it is “taken away in one night, or two at most, any bruise, black or blew spots gotten by falls or women’s wilfulness, in stumbling upon their hasty husbands’ fists.”

67. Dracaena Draco, Linn.

Sex. Syst. Hexandria, Monogynia.

This tree, which has the habit of a palm, is a native of the Canary Islands. Its stem yields by incision a red juice, which concretes and forms a red resin resembling dragon’s blood (see ante, p. 160), which appears to have been collected by the Spaniards when they took possession of those islands. Hence this species has usually passed for one of the sources of dragon’s blood. But none of the commercial article is obtained from it. Indeed, Guibourd states that, at the present time, it is impossible to obtain the smallest quantity of it at the Canary Islands.

One of the Dracaena-trees growing at Orotava has long been celebrated for its great size and age; and next to the Boabab trees (_Adansonia digitata_), it is regarded as one of the oldest inhabitants of the earth.¹

68. Xanthorrhoea, Smith.

Sex. Syst. Hexandria, Monogynia.

(Resina.)

The _Xanthorrhoeas_ or Grass-Trees of Australia differ considerably in habit from the other Liliaceae. Their stems are usually shrubby and resiniferous; their leaves long, narrow, grass-like, and in tufts; and their flowers small, white, and densely crowded on long cylindrical spikes like those of birches (Typha). Mr. Brown has described seven species, viz., _X. arbores_, _australis_, _Hastifolia_, _media_, _minor_, _bracteata_, and _Pumilio_. The first two are arborescent, the third and fourth have short stems, and the last three are stemless.

Two resins, both the produce of this genus, have been imported into this country—one yellow, the other red.

1. The yellow resin of _Xanthorrhoea_, known by the various names of yellow resin of New Holland (Hollandia Belgii), Botany Bay resin, and acaroid resin or gum (resina vel gummi acaroidis), was first noticed by Governor Phillip.² in 1769.

It is obtained from the trunk of one or more species³ of _Xanthorrhoea_ by spontaneous exudation.⁴ It occurs in more or less rounded tears; in flattened pieces, bearing on one side an im-

¹ Jahrh. f. pr. Pharm. vi. 15; vii. 17. (Wittstein’s Vollst, etym. chem. Handwörterbuch, Bd. i. S. 360, 1547.)
² Herbail, 1633.
⁴ Prodromus Flora Nova Hollandiae, 1810. One of the arborescent species (probably _X. arbores_) is called black boy (Drummond, in Hooker’s Journal of Botany, vol. ii. p. 314, 1840).
⁵ Voyage to Botany Bay, 1789.
⁶ Smith (Rees’s Cyclopaedia, vol. xxxix. art. Xanthorrhoea) refers it to _X. hastil_ and some other species (see, also, Bennett’s Wandering in New South Wales, &c. 1834). On the other hand, L. Gmelin (Handb. d. Chem. ii. 615), on the authority of Sieber, and Mertz and De Lens (Diet. Nat. Med. vi. 370, 1834), on the verbal authority of Mr. R. Brown, refer it to _X. arbores_.
pression of the stems to which they were attached, and intermixed with portions of wood, stalks, earth, &c.; and in masses of variable size and irregular shape, having, when fractured, a speckled or granitic character. The pure resin is reddish-yellow. Its fresh fractured surface resembles that of gamboge; its powder is greenish-yellow. When heated, it emits a vapour having a fragrant odour like that of Tolu or storax. It has been repeatedly subjected to chemical examination; viz., by Lichtenstein,\textsuperscript{3} Schrader,\textsuperscript{4} Laugier,\textsuperscript{5} Widmann,\textsuperscript{6} Trommsdorff,\textsuperscript{7} and more recently by Stenhouse.\textsuperscript{8} It consists essentially of resin, cinnamic acid, a small quantity of benzoe acid, and a trace of volatile oil. Some samples contain a small quantity of bassorine. Heated with peroxide of manganese and oil of vitriol, it evolves the odour of the oil of bitter almonds. Its alcoholic solution yields, on the addition of water, a yellow precipitate soluble in caustic potash. By the action of nitric acid it yields so large a portion of carbazic acid that it is likely to prove the best source of that acid. As it sometimes resembles Tolu and storax in composition, so it probably resembles them also in its medicinal properties. Mr. Kite\textsuperscript{9} employed it in several diseases. He says it neither vomits, purges, nor binds the belly; nor does it act materially as a diuretic or diaphoretic. More recently, Dr. Fish\textsuperscript{10} has employed it in the form of tincture with opium in fluctus hepaticus, and the colligative diarrhoea of phthisis. On account of its resemblance in composition to the balsams, it deserves a trial in chronic catarrhs. A tincture of New Holland resin is prepared by digesting the resin in rectified spirit: Kite used equal parts of resin and spirit; Fish, 2 ounces of resin to 1ij of spirit. The dose of the tincture is 3j or 3ij in milk or mucilaginous mixture.—It might be used as a substitute for, or mixed with other substances in the preparation of fumigating pastilles.

2. The red resin of Xanthorrhoea is sometimes imported under the name of black-boy gum. In colour it somewhat resembles dragon's blood, or Botany Bay kino (Eucalyptus resinifera); but many of the pieces, like some of those of the yellow resin of Xanthorrhoea, are marked by the impression of the trunk to which they have adhered. When heated, it evolves a fragrant balsamic odour; and, with the exception of the intermixed and adherent ligneous matters, is completely soluble in rectified spirit. The source of this resin would appear to be X. Hastili; for Vinquet (quoted by Nees Von Esenbeck)\textsuperscript{11} says that this species yields a red resin which resembles dragon's blood.

††† Flowers with a true perianth adherent to the ovary (inferior ovary), usually hermaphrodite.

ORDER XII. IRIDACEÆ, Lindl.—IRIDS, OR CORN-FLAGS.

**Iridi. Juss.**

**Characters.—**Calyx and corolla superior, confounded, their divisions partially cohering, or entirely separate, sometimes irregular, the three petals being occasionally very short. Stamens 3, arising from the base of the sepals; filaments distinct or connate; anthers bursting externally lengthwise, fixed by their base, 2-celled. Ovary 3-celled, cells many-seeded; style 1; stigma 3, often petaloid, sometimes 2-lipped. Capsule 3-celled, 3-valved, with a loculicular dehiscence. Seeds attached to the inner angle of the cell, sometimes to a central column, becoming loose; albumen horary, or densely fleshy; embryo enclosed within it.—Herbaceous plants, or very seldom under-shrubs, usually smooth; the hairs, if any, simple. Roots tuberous or fibrous. Leaves equitant, and distichous in most genera. Inflorescence terminal, in spikes, corymbes, or panicles, or crowded, sometimes radical. Bracts spathaceous, the partial ones often scarious; the sepals occasionally rather herbaceous (Lindley).

**Properties.—**The underground stems and roots usually abound in fecula and mucilage; but these nutritive substances are generally combined with an acid principle, which excludes their employment as articles of food. However, Moraca edulis, M. sisyrinchium, Gladiolus edulis, and a species of Tigridea, have been used as esculent substances. The rhizomes of several species of Iris (as I. Pseudo-acorus, I. germanica, I. sibirica, and I. versicolor) are remarkable, especially in the fresh state, for their acidity, in consequence of which some of them have been used as purgatives, salagogues, or erethines, or for issue-pens. The rhizomes of some species (as I. florentina and I. germanica) have an agreeable smell. The colour and the odour of safron are to be regarded as part of the peetaloid qualities of the stigma of Crocus. The effects of this medicine on the nervous system are regarded by De Candolle\textsuperscript{12} as similar to those of [certain odorous] flowers.

---

5. Geiger's Pharmacie, Bd. ii. S. 178, 2te Aufl. 1839.
69. CROCUS SATIVUS, Allioni.—THE SAFFRON CROCUS.

**Sex. Syst. Triandria, Monogynia.**

(Stigma, L.—Stigmata, E. D.)

**History.**—Saffron is mentioned in the Old Testament. Homer speaks of the *crocus* (χρόκος). Hippocrates employed saffron in uterine and other maladies. The word saffron (za'farān) is probably of Persian origin.

**Botany. Gen. Char.**—Perianth [coloured], with a slender tube twice as long as the limb; limb 6-partite, equal, erect. [Stamens 3, inserted into the tube; anthers sagittate.] Stigmas 3, thick, convoluted, generally crested. Capsule under ground, elevated by a short peduncle from the root, which peduncle elongates after the decay of the flowers, and the capsules appear above ground. (Hooker, with some additions.)

**Sp. Char.**—Stigma protruded, drooping, in 3 deep linear divisions. (Hooker.) Cormus roundish; its brownish coats reticulated, separating superiorly into distinct parallel fibres. Leaves linear, with a white central stripe, and surrounded at their base with long membranous sheaths. Flowers light purple, shorter than the leaves, with a two-valved membranous spathe. Anthers pale yellow. Stigmas deep orange-coloured.

**Hab.**—A native of Asia Minor. Now naturalized in England, France, and some other European countries. It is a doubtful native of the eastern parts of Europe. It is said to have been introduced into Spain by the Arabs. It flowers in September and October.

**Preparation.**—The flowers are gathered in the morning, and the stigmata, with a portion of the style, plucked out for use, the rest of the flower being thrown away. The stigmata are then dried on paper, either by means of portable kilns over which a hair-cloth is stretched, or in a room by the sun. When dried between paper under the pressure of a thick board and weights, the saffron is formed into cakes now no longer to be met with.

**Description.**—The only saffron now found in the shops is that called hay saffron. The article sold as cake saffron is in reality not saffron.

Hay saffron (crocus in feeno) consists of the stigmas with part of the style, which have been very carefully dried. They are from an inch to an inch and a half long, thin, brownish-red; the upper portion (stigma) is expanded, notched at the extremity; the lower portion, which constitutes part of the style (called by Th. Martius' Fontinelle), is narrow, capillary, yellowish. The odour is penetrating, aromatic, and, of large quantities, narcotic. The taste is bitter, somewhat aromatic. When chewed, saffron tingles the mouth and the saliva yellow.

It consists of triparted red filaments having an orange colour; the segments dilated at the apex. Moistened with water and rubbed on paper, it produces an intense orange-coloured stain.

—Ph. Lond.

I find by careful examination that one grain of good commercial saffron contains the stigmata and styles of nine flowers; hence 4,320 flowers are required to yield one ounce of saffron.

1. English saffron (crocus anglicus) is no longer found in commerce.
2. Spanish saffron (crocus hispanicus) constitutes the best saffron of the shops. It is imported from Gibraltar (principally), Cadiz, Denia, Santander, and Malaga. From the concurrent accounts of pharmacologists it would appear that formerly Spanish saffron was spoiled by being dipped in oil to preserve it. But the saffron now imported from Spain has not been subjected to this treatment. Occasionally Spanish, as well as any other kind of saffron, is oiled by the dealers to give it an appearance of freshness.
3. French saffron (crocus gallicus) is usually considered in commerce to be of second quality.

1 Solomon's Song, iv. 14.  
2 Opera, Ed. Farsi, pp. 497, 575, 614, 626, and 676.  
3 Iliad, xiv. 340.  
4 Dillon, Travels through Spain.  
5 Pharmacognosia, 1832.
It is the produce of Gattinias (Gattinias saffron) and Orléanais, which comprehend part of the departments of Seine-et-Marne and Eure-et-Loire, and the whole of the department of Loiret. The saffron of Aougoule is intermixed with the pale style, and is the worst. French saffron is shipped for England at Calais, Boulogne, and Havre.

Besides the preceding, several other varieties of saffron are mentioned by pharmacologists, but they are not distinguished in English commerce, and I am unacquainted with them. Such are Austrian, Bavarian, Oriental, and the Sicilian saffron (C. australicus, bavaricus, orientalis, and sicilienas) mentioned by Murray, Geiger, and others. The saffron of Lower Austria is said to be the best and most costly in Europe, but the produce is scarcely sufficient for the home consumption; and, therefore, saffron is imported into Austria. Austrian saffron is chiefly produced at Ravelbach, Meissau, Eggendorf, Kirchbeg, and Wagram.

From the Customs reports it appears that saffron is occasionally imported into England from Hamburg, Antwerp, Genoa, Naples, and Bombay. But I am ignorant of its place of growth and quality. According to Gussone, Crocus odorats yields Sicilian saffron. Dioscorides considered the saffron of Corycus (a mountain of Cilicia, in Asia Minor, now called Curo) to be the best, and that of Lycia and Olympus to be of second quality; while Cyrenaic saffron, as well as that from Centuripinum (Centorbe) in Sicily, he declares to be the worst.

Saffron (crocus in placenta) was formerly prepared by compressing hay saffron. But the cakes now met with in the inferior shops are composed of Safflower (Carthamus tinctorius) and gum-water, made into a paste, and rolled out on a tin plate with a rolling-pin into oval cakes of 11 inches long, 10 inches broad, and about one-tenth of an inch thick. These are dried on brown paper in a stove. They are shining, and of a brownish-red colour. I can detect neither saffron nor marigolds (Calendula officinalis) in them. Their price is considerably less than that of good hay saffron. I am informed by a maker of cake saffron that there is only another person besides himself by whom this substance is made in London.

Adulteration.—To increase the weight of saffron, it is said to be sometimes intermixed with sand or grains of lead. To detect these, it is sufficient to scatter the saffron loosely over a sheet of white paper, when the sand or grains of lead fall out.

To give saffron flexibility and an appearance of freshness, as well as to augment its weight, it is sometimes dampened or oiled. To detect either water or oil, a small portion of saffron should be subjected to pressure between folds of white blotting paper; if this become either moistened or greased, the adulteration is obvious.

Another adulteration practised on saffron is intermixing it with the petals of some plant; usually of safflower (Carthamus tinctorius), which is sometimes called bastard saffron. The safflower readily escapes the eye of a superficial observer. If rubbed with the moistened finger on paper, it produces a slightly yellow mark only, whereas genuine saffron causes a very intense orange-yellow stain. The fraud may also be detected by carefully examining the suspected portion by a magnifying glass. The fraud is the more easily detected if the suspected saffron be previously macerated in hot water. Genuine saffron consists of a filiform style, divided at one extremity into three long, convoluted, deep orange stigmata, which are a little dilated upwards and notched at the extremity. Safflower, on the other hand, is composed of florets, each consisting of a monopetalous, tubular, 5-toothed red corolla, inclosing 5 syngenesious stamina and a style. Moreover, the corolla is devoid of the softness and flexibility of the stigmata of saffron; but is, on the contrary, dry and brittle.

Other florets, or strips of petals, artificially dyed to give them colour, and greased with oil to render them supple, have been employed to adulterate saffron. Guibourt mentions the marigold (Calendula officinalis), Arnica, and soapwort (Saponaria), as having been used for this purpose. By attention to the above-mentioned characters of saffron, the fraud may be readily detected. The dilated extremities of the stigmata of saffron are broader than the style; whereas the extremities of the divisions of a strip of a petal will usually be found narrower than the body of the strip.

1 Guibourt, Histoire des Drag. ii. 194, 4ème édit. 1849.
3 Handbook of Pharmacy.
5 Lindley, Flora Medica.
6 Trade List for 1837-8-9.
7 Lib. i. cap. xxv.
Genuine saffron, from which the colouring matter has been extracted, is sometimes found in commerce. The sample which I have seen had the essential characters of the stigma of saffron, but wanted the softness and flexibility of good saffron, and was somewhat darker coloured. It did not present the pale yellow filaments (styles) of ordinary saffron, and imparted no colour to spirit of wine.

Fibres of smoked beef are said to have been used for adulterating saffron.

COMMERCE.—The quantity of saffron on which duty (of 1s. per lb.) is paid is about 5,000 lbs. per annum. The places from which it is imported have been already mentioned. It is brought over in cases, barrels, and boxes.

COMPOSITION.—Saffron was analyzed, in 1811, by Vogel and Bouillon-Lagrange, and in 1818 by Aschoff.*

1. Volatile Oil of Saffron. (Oleum Croci)—Obtained by distilling saffron with water. It is yellow, heavier than water, has a burning, acrid, somewhat bitter taste, and is slightly soluble in water. By keeping, it becomes white, solid, and lighter than water. On it depend probably the medicinal properties of saffron.

2. Colouring Matter: Polychroite (so called from πολύς, many, and χρώς, colour, in consequence of its being susceptible of numerous changes of colour).—By digesting the aqueous extract of saffron in alcohol, and evaporating the tincture to dryness, a substance is obtained which Bouillon-Lagrange and Vogel called polychroite, but which Henry5 has separated into volatile oil and a bitter red substance (polychroite properly so called). Pure polychroite is pungent, bitter, scarlet-red, odourless, slightly soluble in cold water, much more so in hot water, readily soluble in alcohol and oils (both fixed and volatile), slightly soluble in ether. Sulphuric acid turns it blue, then lilac. Nitric acid makes it green, but the colour is very fugitive. The hypochlorites destroy the yellow colour of a solution of polychroite.

CHEMICAL CHARACTERISTICS.—An aqueous infusion of saffron gives no indication of starch on the addition of a solution of iodide. The hypochlorites bleach it. Sulphuric and nitric acids act on it as on polychroite above mentioned. Acetate of lead causes no precipitate. By evaporation, the infusion yields an extract from which alcohol removes the colouring matter and leaves a gummy substance.

PHYSIOLOGICAL EFFECTS.—Formerly, saffron was considered to be cordial, aromatic, narcotic, and emmenagogue. Some have accused it of causing laughing delirium; others have ascribed to its use great mental dejection; and several have declared that they have seen immoderate uterine hemorrhage produced by it, which, in the case referred to by Riverius, is said to have terminated fatally. But modern experience has proved that most of these statements are erroneous. Alexander swallowed four scruples of saffron without perceiving any obvious effects therefrom; and Wibmer took a drachm without observing the slightest effect.

By the long-continued use of saffron, the colouring particles become absorbed, and tinge the secretions, especially the urine and perspiration. In some instances, the fetus in utero has been stained by it.10 The failure of Alexander to detect the yellow tinge in his secretions arose probably from the short time he had been using this medicine. Mr. Gibson11 gave a considerable quantity of saffron to a pigeon, which thereby had its feces tinged, yet no perceptible alteration was produced in its bones.

---

5. *Vogel.*
Headache, prostration of strength, apoplexy, and even death, have been ascribed to the inhalation of the vapour arising from large quantities of saffron; and perhaps correctly so, for it is well known that the odours of other plants (as the rose, the pink, &c.) act on some individuals as narcotic poisons.

USES.—Saffron is employed, especially on the Continent, as a flavouring and colouring ingredient in various culinary preparations, articles of confectionery, liqueurs, &c. It was used by the ancients as a perfume as well as a seasoning agent.

In the modern practice of medicine, it is used chiefly as a colouring ingredient. It is a popular remedy for assisting the eruption of exanthematous diseases; on the same principle, I suppose, that bird-fanciers give it to birds when mounting. It was at one time esteemed as an antispasmodic in asthma, hysteria, and erupation of the stomach; and was formerly used as an emmenagogue, and to promote uterine contractions and the locohal discharge. Lastly, it has been employed as a stimulant to the nervous system in hypochondriasis.

ADMINISTRATION.—It may be given in doses of from ten grains to a drachm, in the form of powder or pill. It is popularly used in the form of infusion or tea.

1. SYRUPUS CROCI, L. E. D.; Syrup of Saffron.—(Saffron [chopped fine, D.]
   3v [3x, E.; 3ss, D.]; Boiling Distilled Water Oj; Sugar ßbij [or as much as may be sufficient; Rectified Spirit, f3ijss or as much as may be sufficient, L.]
   Macerate the saffron in the water for twelve hours, in a vessel lightly covered, then strain the liquor and add the sugar to it. To the syrup, when cold, add the spirit.)
   —It is employed principally for its colour.

2. TINCTURA CROCI, E. D.; Tincture of Saffron.—(Saffron, chopped fine, f3ij; Proof Spirit Oj [Oj; D.].
   Macerate for fourteen days, strain, express, and filter, D.—This tincture is to be prepared like tincture of cinchona, either by percolation or by digestion, the former method being the more convenient and expeditious, E.)
   —Used as a colouring liquid. It is also employed as a stimulant and emmenagogue in doses of from f3ij to f5ij.

As a colouring and flavouring ingredient, saffron is a constituent of several other preparations.

70. Iris florentina, Linn.—Florentine Orris.
   Sex. Syst. Triandria, Monogynia.
   (Rhizoma.)

The orris root (radix iridis florentina) of the shops consists of the rhizomes of three species of Iris; namely, I. florentia, I. pallida, and I. germanica. They acquire their well-known violet odour while drying. They are brought to us in the decorated state, in casks, from Leghorn and Trieste.

Orris root consists, according to Vogel, of volatile oil, acrid resin, astringent extractive, gum, starch, and ligneous matter. Raspail detected in it crystals, which he considered to be those of oxalate of lime. The starch of orris root consists of elliptical-shaped particles, which form interesting objects for the polarizing microscope. Some of them consist of two mullar-shaped particles applied base to base. Most of them are cracked at the hilum, and even at their edges.

The most prevalent-sized particle is marked #.
This genus contains two species, which deserve a short notice.

1. **TACCA PINNATIFIDA**, Roxb., Fl. Ind. ii. 172.—A native of the Moluccas and Malay countries. The tuberous roots are intensely bitter when raw, but yield a large quantity of beautifully white starch, used for puddings, cakes, and other articles of confectionery. The tubers "are the tacca yoy of some navigators; they form an article of diet in China and Cochlin China, as also in Travancore," where, according to Dr. Ainslie, they attain a large size, and are eaten by the natives, with some acid, to subdue their acrimony.

2. **TACCA OCEANICA**, Nuttal, Amer. Journ. of Pharm. vol. ix. p. 306.—A native of Tahiti, and other islands of the South Sea. Until Mr. Nuttal pointed out its peculiarities, it was supposed to be identical with *T. pinnatifida*. Ellis says that the "pi, or arrow-root, *chilka tacca*" grows on the high sandy banks near the sea, or on the sides of the lower mountains.

The tuberous roots yield a highly nutritious fecula. At Tahiti (Otheihe), this fecula is procured by washing the tubers, scraping off their outer skin, and then reducing them to a pulp by friction on a kind of board made by winding coarse twine (formed of the cocoa-nut fibre) regularly round a board. The pulp is washed with sea-water through a sieve, made of the fibrous web which protects the young frond of the cocoa-nut palm. The strained liquor is received in a wooden trough, in which the fecula is deposited; and the supernatant liquor being poured off, the sediment is formed into balls, which are dried in the sun for 12 or 24 hours, then broken and reduced to powder, which is spread out in the sun to dry.

**Tacca starch**, or Tahiti arrow-root, sometimes called *Otheiteia salep*, is imported into London, and sold as "Arrow-root, prepared by the native converts at the Missionary stations in the South Sea Islands." It is a white amylaceous powder, with a slightly musty odour. Examined by the microscope, I find it to consist of particles which appear circular, mullar-shaped, or polyhedral. Some of the mullar-shaped particles are slightly narrowed at the base. Moreover, the base of the mullar, instead of being flat, appears to me to be hollowed out. The hilum is

---

**Schleiden** describes the starch particles of *Iris florentina* and kindred species as being perfectly hollow, and apparently cup-shaped.

Orris root is an acid substance, and in full doses causes vomiting and purging. It is principally used on account of its violet odour. Thus *hair and tooth powders, perfumed oils, &c.*, are frequently scented with it. Issue peans (*pois d’iris*) have been made of it. During teething, infants are sometimes permitted to rub their gums with, and bite the rhizome; but the practice is objectionable, since it is not unfrequently attended with irritation of the mouth, and disorder of the stomach and bowels. Furthermore, the danger of the rhizome getting into the oesophagus or trachea is not to be overlooked. One fatal case of this kind is recorded. Powdered orris root is sometimes used as an empline.

A *tinctura of orris root* (*tinctura iris florentina*), prepared by digesting one part of powdered orris root in eight parts of rectified spirit, is used as a scent, and is frequently sold as *essence of violets, or eau de violettes*.

---

**ORDER XIII. TACCACEÆ, Lindley.**

**Characters.**—A small and imperfectly known order of endogenous plants, with tuberous roots, leaves with curved parallel veins, hermaphrodite regular flowers, a petaloid tubular, 6-parted perianth, 6 stamens, a 1-celled inferior ovary, and seeds with fleshy albumen.

**Properties.**—The tuberous roots are bitter and acrid, but by cultivation become larger and milder. They yield a large quantity of nutritive farina.

The most prevalent-sized particle is marked thus *.
small and circular; it cracks in a linear or stellate manner. The rings are few and not very distinct.

This secta is used as a substitute for the West Indian Arrow-root, to which it would probably be equal if it were prepared with equal care. Its composition, like that of other starches, is presumed to be $\text{C}_6\text{H}_{10}\text{O}_5$.

**ORDER XIV. AMARYLLIDACEÆ, Lindl.—AMARYLLIDS.**

None of the plants of this order are employed in England as articles of the Materia Medica. Yet many of them act powerfully on the system, and one of them (Hemanthus toxiccarina) is said to be used by the Hottentots to poison their arrow-heads. The prevailing property of the order is acridity, which is possessed principally by the bulbs, several of which (as those of Pancratium maritimum and Hemanthus cocineus) seem to be endowed with properties very similar to those of squill. The leaves and flowers of Narcissus Pseudo-Narcissus or Daffodil are enumerated among the simples of the French Codex. In doses of 20 or 30 grains they sometimes cause vomiting. They have been employed in spasmodic affections (as hooping-cough), in diarrhoea, and in aegua. Several other species of Narcissus, as N. Tazetta and N. odoratus, also possess emetic properties. Narcissus Tazetta, the Italian or Polyanthus Narcissus, is supposed by Dr. Sibthorp to be the Narcissus of the poets. The root and succulent leaves of the Agava Americana or American alc, a native of Tropical America, yield a saccharine juice which lathers like soap, and when fresh is said to be laxative, diuretic, and emmenagogue. By fermentation it yields an acid liquor. The ligneous fibres of the leaves and roots are used as a thread (pila thread).

**ORDER XV. MUSACEÆ, Agardh.**

**Characters.**—Leaves with veins curved, and proceeding from the midrib to the margin (curved-vincent). Perianth 6-parted, adherent, petaloid, irregular; Stamina normally 6, by abortion usually 5; Anthers 2-celled. Ovary inferior, 3-celled. Fruit 3-celled. Seed albuminous.

**Properties.**—An important order of endogens, whose fruits (bananas and plantains) form a valuable article of food in some tropical regions.

72. **Musa sapientum, Linn.—Plantain; Banana.**

_Sex. Syst. Pentandria, Monogynia._ 1

( Fructis; Amylum).

Plantains (Musa paradisiaca, Linn.) and Bananas (Musa sapientum, Linn.) are probably only varieties of the same species. The former have a stem wholly green, and persistent male flowers; the latter have a spotted stem, deciduous male flowers, and shorter and rounder fruit. Numerous varieties of each are cultivated in the tropical parts of Asia, Africa, and America; the wild parent is found at Chittagong, and other parts of tropical Asia. The fruit is a berry, and in the unripe state acorns in starch; but during maturation this disappears, being converted into a mucilaginous substance and this into sugar, so that in the ripe fruit not an atom of starch can be detected. 2

Boissinger 3 analyzed the ripe fruit of Musa paradisiaca, and found in it sugar, gum, maltic, gallic, and pectic acids, albumen, and lignin.

Plantains and bananas form important and valuable articles of food to the inhabitants of many tropical regions. "But for plantains," says Dr. Wright, 4 Jamaica would scarcely be habitable, as no species of provision could supply their place. Even flour, or bread itself, would be less agreeable and less able to support the laborious negro, so as to enable him to do his business, or to keep in health."

Humboldt 5 calculates that, as 33 lbs. of wheat and 90 lbs. of potatoes require the same space as that in which 4,000 lbs. of bananas are grown, the produce of bananas is consequently to that of wheat as 133:1, and to that of potatoes as 44:1. Dr. Shier, 6 in an interesting report on the starch-producing plants of British Guiana, has given

1 Mérat and De Lens, _Dict. de Mat. Méd._ t. iv.
2 De Candolle, _Essai sur les Propriétés Méd._
3 I have followed Roxburgh ( _Fl. Indica_, vol. 1) in referring this genus to Pentandria, Monogynia. In Reichard's edition of Linnaeus's _Systema Plantarum_ (1759), it is placed in Polygium, Monogynia; and in Loudon's _Encyclopedia of Plants_, it is referred to Hexandria, Monogynia.
4 _Avequin, Journ. de Pharm._ t. xxiv. p. 555, 1858.
5 _Journ. de Pharmacie_, xxii. 355.
7 Humboldt's _Pl. Equino_; also, _Library of Entertaining Knowledge—Vegetable Substances._
us some interesting details respecting the plantain. He states that "a new plantain walk in this colony will yield 450 bunches of 50 lbs. each, of which, as nearly as possible, 50 per cent. will be core, containing 17 per cent of starch, thus producing 17 cwt. of starch per acre." I am indebted to this gentleman for specimens of the sliced plantain core dried, plantain meal, and plantain starch, prepared in April 1847.

Fig. 222.  Fig. 223.

The Plantain.  The Banana.

a. Sliced Plantain core.—The sample sent to me by Dr. Shier was prepared in April, 1847. It was obtained by stripping off the husk of the plantain, slicing the core, and drying it in the sun. The dried slices, as I have received them, are segments of circles from \( \frac{1}{2} \) to \( \frac{3}{4} \) of an inch in diameter, and \( \frac{1}{4} \) to \( \frac{3}{4} \) of an inch in thickness. Their prevailing tint is whitish, like that of dried slices of colchicum corni, but marbled with reddish veins. Their colour is fragrant, and somewhat similar to that of orris root. Their taste is farinaceous.

b. Plantain meal; Conquin-tay.—Obtained by powdering and sifting the thoroughly dried sliced plantain core. It is known among the creoles of the colony by the name of Conquin-tay. It is a whitish meal, speckled with minute dark-reddish spots. Its colour is fragrant, and similar to that of orris root (Dr. Shier says it resembles fresh hay or tea). Its taste is bland, like that of common wheat flour. When examined by the microscope, it is seen to consist chiefly of starch grains. According to Dr. Shier's statement, plantain meal contains about 68 per cent. of starch. 100.0 parts of plantain meal yielded Dr. Shier 0.88 parts of nitrogen. If this number be multiplied by 6.5 (see ante, p. 106, foot-note), we have 5.72 as the per centage amount of proteinaceous matter (albumen, gluten, &c.) contained in plantain meal.

It is obvious, therefore, that plantain meal must be greatly superior to the pure starches, inasmuch as it contains blood- and flesh-making principles which the latter are devoid of. Dr. Shier states that it is easy of digestion, and that it is largely employed in British Guiana as the food of infants, children, and invalids; but it will not serve for the manufacture of macaroni, as this, when made from it, falls to powder when put into hot water. The same authority tells us that the plantain yields about 20 or 25 per cent. of meal.

c. Plantain starch.—This is obtained from the plantain by rasping and washing; but owing to the flesh-coloured tissue in which the starch is imbedded being somewhat denser than the latter, it settles below the starch, and it is somewhat difficult to separate completely the finer parts of it from the starch; hence the latter is not perfectly white. The plantain yields about 17 per cent. of starch. Examined by the microscope, I find the starch grains\(^1\) to be flat, transparent disks, like those of the starch of Zingiberaeeae; hence they have but little lateral shading, and when superimposed the contour of the lower grains can be seen through the upper ones. Their shape is more or less elliptical and ovate, the extremity at which the so-called nucleus or hilum is placed being narrower than the opposite one. When viewed edgewise, their shape appears to be linear, and the lateral shading is stronger.

\(^1\) The following measurements, in parts of an English inch, of the particles of plantain starch (prepared by Dr. Shier, of Demerara) were kindly made for me by Mr. George Jackson:

The most prevalent-sized particles are marked thus *.
The lines or segments of rings seen on the flat surfaces of the grains do not extend to the edges of the grain, nor do they surround the hilum. When examined by the polarizing microscope, these grains present the well-known crosses. In its chemical, dietetical, and medicinal properties, the starch of the plantains agrees with those of other starches.

ORDER XVI. MARANTACEÆ, Lindl.

Cannaceæ, Agardh.

Characters.—Calyx superior, of 3 sepals, short. Corolla tubular, irregular, with the segments in 2 whorls; the outer 3-parted, nearly equal, the inner very irregular; one of the lateral segments usually coloured, and formed differently from the rest; sometimes by abortion fewer than 3. Stamens 3, petaloid, distinct, of which one of the lateral and the intermediate one are either inactive or abortive, and the other lateral one fertile. Filament petaloid, either entire or 2-lobed, one of the lobes bearing the anther on its edge. Anther 1-celled, opening longitudinally. Pollen round (papillose in Canna cocinea, smooth in Calathea sebrina). Ovary 3-celled; ovules solitary and erect, or numerous and attached to the axis of each shell; style petaloid or swollen; stigma either the mere denuded apex of the style, or hollow, hooded, and incurved. Fruit capsular, as in Scitamineæ. Seeds round, without aril; albumen hard, somewhat floury; embryo straight, naked, its radicle lying against the hilum. Herbsaceous tropical plants, destitute of aroma. Rhizome often tuberous, and abounding in starch. Stem often branching. (Lindley.)

Properties.—The rhizomes frequently abound in starch.

73. MARANTA ARUNDINACEA, Linn.—THE WEST INDIAN ARROW-ROOT.

Sex. Syst. Monandria, Monogynia.

(Tuberis fecula. Ph. Lond.—Fecula of the tubers; Arrow-root. Ed., D.)

History.—This plant was brought from the island of Dominica, by Colonel James Walker, to Barbados, and there planted. From thence it was sent to Jamaica. That gentleman observed that the native Indians used the root against the poison of their arrows, by mashing and applying it to the poisoned wounds.¹

The valuable properties of the starch made from the root are mentioned by Hughes,² in 1751, and the mode of procuring it described by Browne,² in 1789.

Botany. Gen. Char.—Corolla unequal, one of the inner segments in the form of a lip. Stamens petaloid, with half an anther on its edge. Style hooded, adhering to the edge of a sterile filiment. Ovary 3-celled, smooth; ovules solitary. Fruit even, dry, 1-seeded.—Caulescent plants with fleshy rhizomata or tubers. Stems branched, often dichotomous. Inflorescence terminal, panicked, jointed, with glumaceous, deciduous bracts. (Lindley.)

Rhizome white, articulately, tuberous, placed horizontally in the earth, and giving origin to several tuberous jointed stolons (stolones tuberosi), similar to itself, but covered with scales. Those stolons are often more than a foot long, and curved, so that the points rise out of the earth and become new plants (Nees and Ebermaier). Stem two or three feet high. Leaves alternate, with long, leafy, hairy sheaths. Flowers white and small.

The Moranta indica, Tussac,¹ is, botanically, characterized by its leaves being smooth on both sides, and by its seeds; those of M. arundinaecea being violet. But, after a careful examination, Wickstrom declares that Tussac’s plant is identical with the M. arundinaecea, Linn.⁵

Hab.—West Indies. It is cultivated both in the West and East Indies, Ceylon, Sierra Leone, &c.

Composition of the Root.—According to P. C. Benzon,⁶ the root of the Maranta

¹ Siennae Jamaica, vol. i. p. 284. ² The Natural History of Barbados, p. 251, 1759.
² The Civil and Natural History of Jamaica, p. 112, 1789. ⁶ Journ. Bot. iii. 11.
The West Indian Arrow-root:—Commerce.

has the following composition: volatile oil, 0.07; gummy extract, 0.50; starch, 26.00; woody fibre, 6.00; albumen, 1.58; muriate of lime, 0.25; and water, 65.600.

The per centage quantity of starch obtained from the root has been thus stated by other authorities: 7.51 (Dr. J. Clark), 1 12.5 (De Candolle), 2 21.43 (Dr. Shier 3 from roots scarcely ripe).

Extraction of the Fecula.—The starch, or fecula, is extracted from the roots (tubers) when these are about ten or twelve months old. The process is entirely a mechanical one, and is performed either by hand or by machine.

In Jamaica, it is procured as follows: The tubers are dug up, well washed in water, and then beaten in large, deep, wooden mortars to a pulp. This is thrown into a large tub of clean water. The whole is then well stirred, and the fibrous part wrung out by the hands and thrown away. The milky liquor being passed through a hair-sieve, or coarse cloth, is suffered to settle, and the clear water is drained off. At the bottom of the vessel is a white mass, which is again mixed with clean water and drained; lastly, the mass is dried on sheets in the sun, and is pure starch. 4

In Bermuda the roots are first deprived of their paper-like scales, and then rasped by a kind of wheel-rasp (something like Fig. 224, p. 228), and the fecula well washed through sieves and carefully dried.

Upon the Hopewell estate, in the Island St. Vincent, the carefully-skinned tubers are washed, then ground in a mill, and the pulp washed in tinned-copper cylindrical washing-machines. The fecula is subsequently dried in drying houses. In order to obtain the fecula free from impurity pure water must be used, and great care and attention paid in every step of the process. The skimming or peeling of the tubers must be performed with great nicety, as the cuticle contains a resinous matter, which imparts colour and a disagreeable flavour to the starch. German silver palettes are used for skinning the deposited fecula, and shovels of the same metal for packing the dried fecula. The drying is effected in pans covered by white gauze to exclude dust and insects.

COMMERCE.—Arrow-root is brought, in tin cases and in barrels and boxes, from the West India Islands (Jamaica, Barbados, Antigua, St. Vincent, Dominica, Bermuda, St. Kitt's, Grenada, Demerara, and Berbice), Calcutta, and Sierra Leone.

The packages of West-Indian arrow-root sent to this country are lined with paper attached with arrow-root paste. When sent to this country in the hold of the ship, their contents are easily tainted by noisome effluvia.

Arrow-root is usually distinguished by the name of the island or place producing it; as Bermuda arrow-root, St. Vincent's arrow-root, Jamaica arrow-root, African or Sierra-Leone arrow-root, &c. Bermuda arrow-root is the most esteemed variety. In 1845, about 400,000 lbs. were manufactured, of which more than three-fourths came to England. Dr. Ure says that the St. Vincent's arrow-root prepared on the Hopewell estate vies with the Bermuda sort.

In commerce, the term arrow-root is frequently used generically to indicate a starch or fecula. The following are illustrations of its use in this way:—

Portland Arrow-root is obtained from Arum maculatum (see ante, p. 158).

East India Arrow-root is the fecula procured from Curcuma angustifolia, and will be described hereafter. But the West Indian plant (Maranta arundinacea) is also cultivated in the East Indies, and the fecula obtained therefrom is exported from thence, and might with equal propriety be called East India arrow-root.

Brazilian Arrow-root is the fecula of Jatropha Manihot, and will be noticed hereafter (vide Euphorbiaceae).

Tahiti Arrow-root is the fecula of Tacca oceanica, and has already been noticed (see ante, p. 221).

VOL. II.—15
VEGETABLES.—NAT. ORD. MARANTACEAE.

Properties.—The starch or fecula (amylo vel *fexula marantæ*), called in the shops *West Indian arrow-root*, or simply *arrow-root*, is white, odourless, and tasteless. It is in the form either of a light opake white powder, or of small pulverulent masses. When passed between the fingers, it feels firm, and, when rubbed, produces a slight crackling noise. When viewed by a good pocket lens, it is seen to consist of glistening particles. When examined by a microscope, these are seen to be convex, more or less elliptical, and moderately uniform in size. The shape is more or less irregular, but often oblong, or usually somewhat ovate-oblong, frequently obscurely triangular, or oyster-shaped, or mussel-shaped. After having been digested for a short time in water, one, or rarely two, mammillary processes are, in some samples, seen projecting from the surface of some of the particles. In some specimens, these processes have appeared like short spines. The rings are very distinct, though fine. The nucleus, central cavity, or hilum is usually very distinct, generally towards one end of the particle normally circular, but frequently cracked in a linear or stellate manner. When viewed by the polarizing microscope, the particles show very distinct crosses: the junction of the arms of the cross indicates the position of the hilum.

Composition of the Starch.—Arrow-root has been analyzed by Dr. Prout and by Payen, who obtained the following results:

<table>

<td>Arrow-root</td>
<td>100.0</td>
</tr>
</tbody>
</table>

The formula which agrees with Prout’s third analysis is \( \text{C}_{12}\text{H}_{22}\text{O}_{10} \).

Dr. Prout regards arrow-root as a low variety of starch analogous to the low sugar of honey; while wheat-starch he considers to be the most perfect form of starch, analogous to sugar-candy.

Substitutions, Impurities, and Adulterations.—The presence of accidental impurities (such as insects, dust, &c.) may be readily detected by alterations in the colour, odour, and flavour of the arrow-root.

Other cheaper feculas are sometimes substituted for the genuine arrow-root; especially tapioca-meal, potato-starch, and tapioca-starch or Brazilian arrow-root.

The fraud is readily detected by the microscope. When squeezed in the hand, the tapioca-meal cracks like arrow-root; but when submitted to microscopic examination, the truncated extremity of many of the particles giving them either a mullar shape or dihedral summit, the irregular or tuberculated surface, and the size of the particles, readied served to distinguish it from arrow-root.

1 The following measurements, in parts of an English inch, of the particles of *West India* arrow-root, were kindly made for me by Mr. George Jacaikan:

The most prevalent-sized particle is distinguished thus *.

2 Schleiden (*Principles of Scientific Botany*) describes the granules as being compound, without evident central cavity, and always exhibiting the smooth connecting surfaces; but this description does not apply to commercial *West Indian* arrow-root. Raspail has depicted the grains of the fecula of Convolvulus Balans for arrow-root (see Payen, *Ann. Scienc. Nat.*, 2de Sér. 1 x. Botanique, p. 13, 1558).

3 *Phil. Trans.* 1837.

5 *Lancei*, Feb. 1, 1551.
Potato-starch is sometimes sold for West Indian arrow-root. I have met with it in commerce under the name of English arrow-root. It is devoid of the dull or dead white appearance presented by West India arrow-root. The naked eye, or still better a pocket lens, readily distinguishes its large glistening particles from those of genuine arrow-root. The microscope instantly detects the difference. The particles of potato-starch are larger than those of arrow-root, and have coarser and more distinct rings. Moreover, the shape of the particles serves to distinguish them (see Potato-starch). Lampadius observed that potato-starch evolves a peculiar odour when boiled with water and sulphuric acid, and that arrow-root does not evolve this odour when treated in a similar way. Arrow-root, moreover, "is destitute of that fetid, unwholesome oil, extractible by alcohol from potato-starch."

Mixed with one and a half, or twice its weight, of concentrated hydrochloric acid, arrow-root yields an opake paste, whereas that produced by potato-starch is transparent. Arrow-root takes a longer time than potato-starch to become viscid when mixed with equal parts of acid and water.

Other kind of feculas, which are said to have been substituted (on account of their cheapness) for the genuine arrow-root, such as East India arrow-root or Curcuma starch (see Curcuma angustifolia), and Brazilian arrow-root or tapioca-starch (see Jatropha Manihot), are readily distinguishable by the microscope.

Physiological Effects.—By the Indians of South America, and even by some Europeans, the roots (tubers) have been supposed to possess alexipharinic properties. But their chief if not their only real value is that of yielding the starch called arrow-root, which is a much esteemed non-nitrogenized alimentary principle, which, like some other agents of this kind (see vol. i. p. 116), are useful in the animal economy for the production of fatty and saccharine matters, lactic acid, and heat. Arrow-root is one of the most palatable and digestible of the starches.

Uses.—The roots (tubers) have been used by the South American Indians to counteract the effects of wounds inflicted by poisoned arrows. Very recently the expressed juice of the root has been lauded as an antidote to poisons taken into the stomach, and to the bites and stings of venomous insects and reptiles.

The starch or arrow-root is employed at the table as an article of food, in the forms of puddings. It forms an agreeable, non-irritating diet for invalids or infants. In irritation of the alimentary canal, of the pulmonary organs, or of the urinary apparatus, it is especially valuable as a nutritive, emollient, and demulcent.

Administration.—To invalids and infants arrow-root (the starch) is exhibited when boiled in water or milk and flavoured. Milk disagrees with some patients, and in such is of course to be avoided. The addition of sugar improves the flavour and increases the nutritive qualities. Spices, lemon juice, or wine may be employed according to circumstances.

74. Canna edulis, Ker.—Tous-les-Mois?

(Canna. Fecula of the root of an imperfectly determined species of Canna. Tous-les-Mois, E.—The root is supposed to furnish the fecula called Tous-les-Mois, D.)

The starch or fecula called Tous-les-Mois was introduced to the notice of the British public by the late Mr. Opherti of St. Kitts, about 1836. It was at first stated to be the produce of C. coccinea; but as this species, like C. indica, has fibrous, and not tuberous roots, it is tolerably clear that this cannot be the source of the starch in question.

There is good reason for believing that C. edulis of Ker is a native of the West Indies, and that it is the species which yields tous les-mois. Descourtis and Luman speak of a species of

---

2 Ure, Recent Improvements in Arts, Manufactures, and Mines, p. 10, 1814.
4 Slome's Jamaica, vol. i. p. 254.
Canna with fleshy tuberous roots, which grows in the West Indies, and which they call C. indica. But the character of the roots just mentioned shows that the West Indian plant is not C. indica, Linn. Ruiz and Pavon¹ speak of a South American plant which they term Canna indica of Limnea, whose fleshy tubers are eaten by the Peruvians, who call the plant *Archira.* They considered it to be the C. Indica of Linn. But when their herbarium came into Mr. Lambert's possession, he raised plants from the seeds of the original specimens, and found the species to be a new one, which he named *C. edulis.*²

Mr. Lambert afterwards received seeds, from Dr. Gillies of Mendoza, of a Canna known in South America as "*Archira.*" This has been described and figured³ as a new species under the name of *C. achiras* (more properly *C. Achira*); but it is not improbable that it may prove to be identical with *C. edulis.*

*C. glauca* is also said to yield a valuable starch.⁴

My friend Mr. Wordsworth, assistant-surgeon to the London Hospital, and who resided some time at St. Kitts, tells me that he cultivated the *tous-les-Mois* in his garden. Its height was about 4 feet; and its tubers three or four times the size of the fist. In order to extract the starchy, the tubers are rasped by means of a circular or wheel-rasp⁵ worked by a treadle. The tuber is held against the edge of the rasp, at the point marked *a* in the accompanying figure. The starch is obtained from this pulp by the ordinary methods of washing, straining, decantation of the supernatant liquor, and desiccation of the deposited starch.

The quantity of starch procured from the roots of the *tous-les-mois* plant has not been satisfactorily ascertained. Ricord Madiunas⁶ obtained from a pound of the root two ounces of a starch of fine quality: this is equal to 12.5 per cent. It is probable, however, that on the large scale the product would be much greater.

*Tous-les-mois* starch is imported from St. Kitts. To the naked eye it greatly resembles potato-starch. On account of the large size of its particles, it has a satiny or glistening appearance, and is devoid of that dead white or opake appearance presented by the West Indian arrow-root. Examined by a pocket lens, the sparkling and glistening appearance of its particles is very obvious. When submitted to examination by means of the compound microscope, its particles are seen to be very large⁷ (in this respect exceeding those of all other starches), somewhat egg-shaped, to have a very distinct nucleus, central cavity, or hilum, and concentric rings indicative of their laminated structure. Strictly speaking, their shape is oval or oblong; but generally more or less ovate. The circular hilum is usually placed at the narrow extremity; very rarely it is double; once I have seen it treble. The rings are numerous, regular, close, but somewhat unequally so. The hilum and the body of the particle are frequently cracked.

Potato-starch is the only amylaceous substance which can be confounded with *tous-les-mois.* The two starches may be distinguished by a careful attention to their relative sizes and shapes, to the appearance of their rings, the position of the hilum, and the action of polarized light on them.

First, the particles of potato-starch are on the average smaller than those of *tous-les-mois,* and are subject to greater irregularity of size (both as regards different sorts of potatoes and the different particles of the same potato).

Secondly, the larger particles of potato-starch are more irregular in shape than those of *tous-les-mois,* the latter are more constantly rounded or oblong or ovate-oblong; the former are oval, often approximating in shape to an oyster-shell, a mussel-shell, or a triangle with rounded corners, and being frequently gibbous or tumid at different parts of their surface.

Thirdly, the rings seen on particles of *tous-les-mois* are fine, regular, uniform, concentric, and

The most prevalent-sized particles are those marked *#.*
Gingerworts.—The Narrow-Leaved Ginger.

229

crowded; those of potato-starch are coarser, irregular, often excentric, irregularly drawn out, distorted, or more and unequally distant from each other. In potato-starch a greater number of complete rings is visible, and we can trace the lines around the hilum, even in the case of many of the larger rings; but in tous-les-mois this can be done with a very few of the smaller rings only.

Fourthly, in both the hilum is situated nearer to the end of the particle; but in potato-starch this character is less obvious, the hilum frequently being less distant from the centre of the particle than in the case of tous-les-mois.

Lastly, when viewed by polarized light the cross is less frequently regular in potato-starch than in tous-les-mois; in the former, the arms are often distorted.

Tous-les-mois of commerce contains about 16.74 per cent. of hygroscopic water. It is very soluble in boiling water; and, according to Dr. Shier’s experiments, yields a jelly, which is considerably more tenacious than the jelly of any other starch; but which, in clearness or translucency, is inferior to that of arrow-root, and of some other substances.

The composition of tous-les-mois starch is assumed to be the same as that of other starches, viz., C\textsubscript{12}H\textsubscript{22}O\textsubscript{11}.

In its dietetical qualities tous-les-mois resembles other starches (see vol. i. p. 116). It yields very agreeable articles of food for invalids and others, and appears to be very readily digested.

Order XVII. Zingiberaceae, Lindl.—Gingerworts.

Drynárizæ, Vent.—Scitamineæ, R. Brown.

Characters.—Calyx superior, tubular, 3-lobed, short. Corolla tubular, irregular, with 6 segments in 2 whorls; the outer 3-parted, nearly equal, or with the odd segment sometimes differently shaped; the inner (sterile stamens) 3-parted, with the intermediate segment (labellum) larger than the rest, and often 3 lobed, the lateral segments sometimes nearly abortive. Stamens 3, distinct, of which the 2 lateral are abortive, and the intermediate one fertile; this placed opposite the labellum, and arising from the base of the intermediate segment of the outer series of the corolla. Filament not petaloid, often extended beyond the anther in the shape of a lobed or entire appendage. Anther 2-cellcd, opening longitudinally, its lobes often embracing the upper part of the style. Pollen globose, smooth. Ovary 3-cellcd, sometimes imperfectly so; ovules several, attached to a placenta in the axis; style filiform; stigma dilated, hollow. Fruit usually capsular, 3-cellcd, many seeded [sometimes by abortion 1-celled]; occasionally berried (the dissepiments generally central, proceeding from the axis of the valves, at last usually separate from the latter, and of a different texture, R. Br.). Seeds roundish or angular, with or without an aril (albumen floury, its substance radiating, and deficient near the hilum, R. Br.); embryo enclosed within a peculiar membrane (vitellus. R. Br. Prodr. membrane of the amnion, ibid. in King’s Voyage, 21), with which it does not cohere.—Aromatic, tropical, herbaceous plants. Rhizome creeping, often jointed. Stem formed of the cohering base of the leaves, never branching. Leaves simple, sheathing their lamina, often separated from the sheath by a taper neck, and having a single midrib, from which various, simple, crowded veins diverge at an acute angle. Inflorescence either a dense spike, or a raceme, or a sort of panicle, terminal or radical. Flowers arising from among spathaceous membranous bracts, in which they usually lie in pairs. (Lindley.)

Properties.—The rhizomes contain a volatile oil and resin, which confer on them aromatic or acro-aromatic qualities. Many of them abound in starch, the particles of which (like those of plantain starch, see ante, p. 222) are flattened disks. This is sometimes extracted and used as food. Some of them are remarkable for the yellow colouring matter which they yield.

The seeds also contain volatile oil and resin; and possess aromatic or acro-aromatic qualities.

75. Zingiber officinale, Roxb.—The Narrow-Leaved Ginger.

Amomum Zingiber, Linn. D.

Sec. Synt. Monandria, Monogynia.

(Rhizoma, E. E.—Radix, D.)

History.— Dioscorides\textsuperscript{1} and Pliny\textsuperscript{2} speak of ginger: the former calls it Ζυγιάς; the latter zingiberi and zingiberi.

Botany. Gen. Char.—Corolla with the outer limb 3-parted, inner 1-lipped. Filament lengthened beyond the anther into a simple incurved beak. Capsule 3-celled, 3-valved. Seeds numerous, arillate.—Rhizocarpial plants. Rhizomes tu-

\textsuperscript{1} Lib. ii. cap. 190.  \textsuperscript{2} Hist. Nat. lib. xii. cap. 14, ed. Valp.
VEGETABLES.—NAT. ORD. ZINGIBERACEÆ.

berous, articulated, creeping. _Stems_ annual, enclosed in the sheaths of distichous leaves. _Leaves_ membranous. _Spike_ cone-shaped, radical or rarely terminal, solitary, consisting of 1-flowered imbricated bracts (Blume*).

_Sp. Char._—_Leaves_ sub-sessile, linear-lanceolate, smooth. _Spikes_ elevated, oblong. _Bracts_ acute. _Lip_ 3-lobed. (Roxburgh.)

_External._ Biennial. _Stem_ erect and oblique, and invested by the smooth sheaths of the leaves; generally three or four feet high, and annual. _Leaf-sheaths_ smooth, crowned with a bifid _ligula_. _Scapes_ solitary, six to twelve inches high. _Spike_ the size of a man’s thumb. _Lip_ dark purple. _Ovary_ oval, with numerous _ovules_; _style_ filiform; _stigma_ funnel-shaped, ciliate. _Capsule_ roundish, unilocular. _Seeds_ numerous; mostly abortive.*

_Hab._—Cultivated in the tropical regions of Asia and America, and at Sierra Leone. Native soil doubtful, probably Asia.

_Preparation._—Green ginger is sometimes imported from Jamaica. It consists of soft and juicy rhizomes with buds; and appears to have undergone but little preparation beyond picking and washing.

The young shoots put forth every spring by the perennial rhizome are used in the manufacture of the delicious preserved ginger (conditum zingiberis). These shoots are carefully picked, washed, scalded, scraped, peeled, and then preserved in jars with syrup. (Dr. P. Browne.)

The finest preserved ginger is imported from Jamaica usually in jars. Barbados preserved ginger is seldom brought over. The China preserved ginger is stringy. It is sometimes imported in the dried state.

The dried rhizomes, called in the shops ginger (radix zingiberis), are prepared when the stalks are wholly withered, and the rhizomes are about a year old. In Jamaica, this happens in January or February. The rhizomes are dug up and separately picked, washed, and scraped; and afterwards dried in the sun and open air. (Dr. P. Browne.) The product is the uncoated ginger of the shops, formerly called white ginger (zingiber album).

The coated ginger of the shops has obviously not undergone this careful preparation. In Barbados, the rhizomes are dug up, scraped clean, and sun-dried. The black ginger (zingiber nigrum), formerly prepared in Jamaica, is obtained by pickling and cleaning the rhizomes, scalding them gradually in boiling water, and afterwards sun-drying them.4

_Description._—The rhizome, called in commerce ginger root or simply ginger (radix zingiberis), occurs in flattish, jointed, branched, or lobed, palmate pieces, called _races_ or _hands_, which rarely exceed four inches in length.

Barbados ginger, the old sorts brought from Malabar and Bengal, and African ginger, are covered by a dry, shrivelled epidermis commonly called the “coat”; hence these sorts are usually said to be coated or unscraped; whereas the ginger of Jamaica, and the new sorts which of late years have been brought from Malabar and Bengal, have been deprived of their epidermis, and are, therefore, said to be uncoated or scraped. The external colour varies in the different sorts from pale or bright yellow to dark or brown: the palest sort is the fine Jamaica ginger; the darkest being the Bengal old sort; and the other sorts being intermediate. Ginger breaks moderately short, but the fractured surface presents numerous projecting pointed fibres, imbedded in a mealy or farinaceous tissue. A transverse section of the larger and more perfect pieces shows an outer, horny, resinous-looking zone, surrounding a farinaceous centre, which has a speckled appearance from the cut extremities of the fibres and ducts. The internal varies like the external colour; the best ginger is that which cuts pale but bright. The consistence of ginger, as

---

* Ennumeratio Plantarum Javeae.  
* Roxburgh, op. cit.; and Dr. P. Browne, History of Jamaica.  
* Hughes, Nat. Hist. of Barbadoes, p. 233, 1750.  
* Dr. P. Browne, op. cit.—According to Dr. Wright (Lond. Med. Journ. vol. viii.; also, Memoir of the late Dr. Wright, p. 183, 1822), two sorts of ginger are cultivated in Jamaica, viz., the white and the black; the latter has the more numerous and the larger roots.
ascertained by cutting, varies from soft to hard, or, as it is termed in trade, "flinty;" the soft being preferred. The taste of ginger is aromatic, hot, and biting; the odour of a fresh broken piece is peculiar and pungent, though aromatic.

**Varieties.**—Seven kinds of ginger, distinguished partly by their place of growth, and partly by their quality, are known in English commerce. Of these, two are from the West Indies, four from the East Indies, and one from Africa.

A. **West Indian Gingers.**—This division includes Jamaica and Barbados gingers.

1. **Jamaica ginger.**—Imported in barrels holding 1 cwt. each. It is an uncoated, pale sort, and when of fine quality occurs in large, bold, fleshy races, which cut soft, bright, and pale coloured. Inferior samples are small in the race, darker coloured, more or less flinty, and shrivelled.

2. **Barbados ginger.**—Imported in bags of about 60 or 70 lbs. It is a coated sort, in short, flat races, which are darker coloured than Jamaica ginger, and are covered with corrugated epidermis.

B. **East Indian Gingers.**—This division includes two sorts from Malabar and two from Bengal, all of which are more liable to be wormy than either the West Indian or African sorts.

a. **Malabar Gingers.**

3. Coated Malabar Ginger; Unscraped Malabar Ginger; Old sort of Malabar Ginger; Common Malabar Ginger; Bombay Ginger.—Imported from Bombay in bags or packets. It is a coated, dark, small sort.

4. **Uncoated Malabar Ginger; New sort of Malabar Ginger; Tellicherry Ginger; Calicut Ginger; Cochin Ginger.**—A pale, uncoated sort, imported in chests, casks, or bags, sometimes from Tellicherry, but usually from Calicut or Cochin. It resembles Jamaica ginger both in external appearance and flavour; but has externally more of a brownish or reddish tint. It first appeared in English commerce about 1841.

b. **Bengal Gingers.**

5. Coated Bengal Ginger; Common Bengal Ginger; Old sort of Bengal Ginger.—Imported in bags. It is a coated or unscraped dark sort, which cuts flinty and brownish, but is plumper and less wormy than common Malabar ginger.

6. **Uncoated Bengal Ginger; Scraped Bengal Ginger; New sort of Bengal Ginger; Calicut sort of Bengal Ginger.**—Imported in chests of about 1½ cwt. It is an uncoated sort, darker than Jamaica ginger. It is not so large as the uncoated Malabar sort, and is harder and darker.

C. **African Ginger.**—Only one kind of African ginger is known, viz., that from Sierra Leone.

7. **Sierra Leone Ginger; African Ginger.**—Imported in casks or bags. It is a coated sort; the races being generally larger, less flat, and less plump than those of the Barbados sort, which in other respects they resemble.

**Chinese Ginger.**—The Chinese ginger described by Bassermann is unknown in English commerce; the only ginger imported into England from China being preserved ginger.

**Assortment.**—The uncoated gingers, namely, the Jamaica, uncoated Malabar, and uncoated Bengal, are assorted for commercial purposes, according to their qualities, somewhat thus—

1. Bold, soft, and bright ginger.
2. Smaller, but soft and bright.
3. Flinty and dark.
4. Shrivelled, and only fit for grinding.

The Barbados, African, and coated Malabar and Bengal gingers are usually sold un assorted.

The following are the quantities of ginger on which duty was paid for six years:

---

Washed Ginger; Bleached Ginger.—Ginger is sometimes washed in water, and then dried, by wholesale dealers, prior to its being offered for sale to the retailers.

Some of the darker sorts are bleached by washing them in a solution of chloride of lime, and sometimes by exposing them to the fumes of burning sulphur. By this treatment the ginger acquires a chalky-white character, and is then often termed white-washed ginger.

Ginger is said to be sometimes washed in whiting and water (or white-washed) under the pretence of preserving it from insects.

Adulteration.—Powdered ginger is said to be sometimes admixed with flour and other amylaceous substances. The microscope would readily detect the adulteration, except in the case of East Indian arrow-root (Curcuma angustifolia), the particles of which are similar in appearance to those of ginger.

Composition.—Ginger was analyzed in 1817 by Bucholz, and in 1823 by Morin.

1. Volatile oil of Ginger.—Is pale yellow, very fluid, lighter than water, odour that of ginger, taste at first mild, afterwards acrid and hot.

2. Soft Resin.—Obtained by digesting the alcoholic extract of ginger first in water, then in ether, and evaporating the ethereal tincture. The residual resin is yellowish-brown, soft, combustible, has an aromatic odour, and a burning aromatic taste. Is readily soluble in alcohol, ether, oil of turpentine, and hot almond oil.

3. Starch.—Ginger starch consists of thin flat disks, which resemble those of East Indian arrow-root (see Curcuma angustifolia) and plantain starch (see ante, p. 223).

Physiological Effects.—Ginger is one of the aromatic stimulants (see vol. i. p. 253) which possess considerable pungency or acridity. Its dust applied to the mucous membrane of the nostrils acts as an irritant, and provokes sneezing. The rhizome chewed is a powerful salivagogue. The powder mixed with hot water, and applied to the skin, causes a sensation of intense heat and tingling, and slight redness. When taken into the stomach, ginger operates as a stimulant; first, to the alimentary canal; secondly, to the body generally; but especially to the organs of respiration. Like some other spices (the peppers, for instance), it acts as an excitant to the genital organs. Furthermore, it has been said to increase the energy of the cerebral functions. It is less acrid than pepper.

Uses.—Its principal consumption is as a condiment. Its powers in this way are considerable, while its flavour is by no means disagreeable, and its acridity scarcely sufficient to enable it, when taken with food, to irritate or inflame.

As a stomachic and internal stimulant, it serves several important purposes.

---

1 Brande, Dict. of Mat. Med.
2 Gmelin's Handb. d. Chem.
enfeebled and relaxed habits, especially of old and gouty individuals, it promotes digestion, and relieves flatulence and spasm of the stomach and bowels. It checks or prevents nausea and gripping, which are apt to be produced by some drastic purgatives. It covers the nauseous flavour of many medicines, and communicates cordial and carminative qualities to tonic and other agents. As a *sialagogue*, it is sometimes chewed to relieve toothache, relaxed uvula, and paralytic affections of the tongue. As a *counter-irritant*, I have frequently known a ginger plaster (prepared by mixing together powdered ginger and warm water, and spreading the paste on paper or cloth) relieve violent headache when applied to the forehead.

**ADMINISTRATION.**—Powdered ginger may be administered, in doses of from ten grains to a scruple or more, in the form of a pill. Made into a paste with hot water, it may be applied as a *plaster*, as already mentioned.

Preserved ginger (*conditum zingiberis*), though commonly used as a sweetmeat, may be taken with advantage as a medicine to stimulate the stomach. Ginger lozenges, ginger pearls (commonly termed ginger seeds), and ginger pipe are useful articles of confectionery, which are frequently of benefit in dyspepsia accompanied with flatulence.

Essence of ginger is prepared as a tincture, except that the quantity of rhizome should be increased. Some preparers of it concentrate the tincture by distilling off part of the alcohol.

2. **SYRUPUS ZINGIBERIS**, L. E. D. [*U. S.*]; *Syrup of Ginger.*—(Ginger, sliced, *f*5ijs; Boiling Distilled Water Oij; Sugar *f*1bijd, or as much as may be sufficient [Rectified Spirit as much as may be sufficient, *L*.].) Macerate the ginger in the water for four hours, and strain; then add the sugar, and dissolve it.—The *Dublin College* directs it to be prepared with Tincture of Ginger *f*3ij, and Simple Syrup *f*3vij. Mix with agitation.)—Used for flavouring. It is scarcely strong enough to be of much value. An extemporaneous syrup may be prepared by adding the tincture of ginger to common syrup. The *Syrupus Zingiberis* of the United States Pharmacopoeia is made by adding *f*5ij of tincture of ginger (prepared with *f*3vij of ginger, and Oij, *wine measure*, of alcohol) to a gallon of syrup, and evaporating the alcohol by a water-bath.

3. **INFUSUM ZINGIBERIS**; *Infusion of Ginger*; *Ginger Tea.*—This is a very useful domestic remedy, and is prepared by digesting from *f*ij to *f*iv of Ginger in *f*3vij of Boiling Water, for two hours. When flavoured, it is employed as a carminative in flatulence, &c., in doses of one or two tablespoonfuls.

4. **CEREVISIA ZINGIBERIS**; *Ginger Beer*; *Ginger Pop.*—For the following excellent formula for the preparation of this popular and agreeable beverage, I am indebted to Mr. Pollock, of Fenchurch Street: *Take of White Sugar 1bxx; Lemon (or Lime) juice *f*5xvij; Honey *f*3ij; Ginger, bruised, *f*3xxij; Water cong. *f*3vij. Boil the ginger in three gallons of water for half an hour; then add the sugar, the juice, and the honey, with the remainder of the water, and strain through a cloth. When cold, add the white of one egg and *f*3ss of essence of lemon; after standing four days, bottle. The bottles are to be laid on their sides in a cellar, and the beer is ready for use in about three weeks. *If a little yeast be used, the beer is ready in a day or two; but in this case it does not keep well.* This yields a very superior beverage, and one which will keep for many months. Lemon-juice may be pur-
chased for sixpence a pint in Botolph Lane, Thames Street. A formula for the preparation of Ginger Beer Powders has already been given (see vol. i. p. 523).

76. Zingiber Cassumunar, Roxburgh.

Sex. Syst. Monandria, Monogynia.

(Radix.)

The root of this plant is a perennial, tuberous, furnished with long, white, fleshy fibres, and jointed like ginger, but much larger; when fresh, of a deep yellow; possessing a strong, not very agreeable, camphoraceous smell, and warm, spicy, bitterish taste, (Roxburgh.) Sir Joseph Banks and Dr. Comb (to whom specimens of it were given) thought that it was the true cassumunar of the shops. But the great resemblance of cassumunar root to round zedoary leads me to think that it is obtained from a species of Curcuma.

About the year 1672, Dr. Pechey received from his brother, factor to the East India Company, a root which was called cassumunar (variously spelt casnumar, casnumar, &c.), rysegone (or risagon), and bengale (or bengalle). These names were probably fictitious, and were merely given to conceal the secret of its nature.

This root is still found in the warehouses of some London druggists, who call it cassumunar root (radix cassumunar), and consider it to be identical with zerumbet root (see Curcuma Zerumbet). It appears to me to be the turmeric-coloured zedoary of Ainslie, the zedoaria radice lutea of Breyerius, the common besaar or lomnon laeac of Rumphius. It occurs in segments (halves or quarters) of an ovoid tuber (which in the dried state must have been about the size of a pigeon's egg), the external surface of which is marked with circular rings and the bases of the root fibres, and is of a dirty turmeric-yellow colour. Internally it is reddish-brown, and has some resemblance, in its colour and pellucidity, to a fresh-fractured surface of Sotctrine aloes. Its flavour is warm and aromatic; its odour is somewhat like that of turmeric. It has not been analyzed. Its effects must be similar to those of zedoary and ginger. It was at one time used in convulsive and other cerebral diseases, but has fallen into disuse.

77. CURCUMA LONGA, Linn.—THE LONG-ROOTED TURMERIC.

Sex. Syst. Monandria, Monogynia.

(Rhizoma, L. E.—Radix, D.)

History.—Turmeric is probably the κουρκον (Cyperus indicus) of Dioscorides. Both he and Pliny state that this Indian Cyperus has the form of ginger, and that, when chewed, it colours the saliva yellow like saffron. The word curcuma is derived from kurlcum, the Persian name for saffron.

Sp. Char.—Bulbs small, and with the numerous, long, palmate tubers, inwardly of a deep, orange yellow. Leaves long-petioled, broad-lanceolate, of a uniform green (Roxburgh).

Hab.—Much cultivated about Calcutta, and in all parts of Bengal, also in China and Cochin-China. One acre yields about 2000 lbs. of the fresh root.

Description.—The tubers, called in the shops turmeric (radix curcumae, seu terra meridia), are of two kinds: one round (curcuma rotunda), the other long (cur-
cuma longa), but both produced on the same plant. The first are round, oval, or ovate, about two inches long, and one inch in diameter, pointed at one end, and marked externally with numerous annular wrinkles. The second are cylindrical, not exceeding the thickness of the little finger; two or three inches long, somewhat contorted, tuberculated. Both kinds are yellowish externally, internally more or less orange-yellow passing into reddish-brown. The fractured surface has a waxy appearance. The odour is aromatic, somewhat analogous to ginger, but peculiar; the taste is aromatic. When chewed, it tinges the saliva yellow. Its powder is orange-yellow. The tubers are frequently worm-eaten.

If a thin slice of turmeric root be examined by the compound microscope, it is seen to consist chiefly of rounded or oblong, yellow, readily separable cells or vesicles, which appear to be filled with a minutely granular matter, and to be contained in an hexagonal cellular tissue. Intermixed with these cells are observed globules of a viscid, oleaginous, orange-coloured liquid. By boiling the slices in rectified spirit, the oleaginous liquid is dissolved, and the cells are deprived of their yellow colour. The colourless cells appear still to be filled with a granular matter. On the addition of iodine, the cells, but not the hexagonal tissue in which they are contained, acquire a dark blue colour, showing their amylaceous nature.

Varieties.—Five varieties of turmeric are known in the English market, namely, China, Bengal, Madras, Malabar or Bombay, and Java turmeric. These are readily distinguishable from each other by their external appearance; but if they were sorted according to their resemblance, the China and Java turmerics would be placed in one group, the Madras and Malabar in a second group, and the Bengal in a third.

1. China Turmeric.—This sort consists of smooth, plump, round, and long tubers (curcuma rotunda et longa, Figs. 225 and 226) of a greenish-yellow hue externally. They yield a bright powder, and on that account are much preferred for medicinal purposes. Hence they fetch a higher price than any other sorts of turmeric. Probably if much of it were brought to market, it would not fetch more than the Bengal sort.

2. Bengal Turmeric.—This sort consists of thin or narrow long tubers (curcuma longa, Fig. 227) which are moderately smooth externally, and of a grayish dull yellow colour. They break with a deep reddish fracture. Although, from the dull appearance of its narrow tubers, it is not a very inviting sort to the inexperienced
eye, yet it fetches a higher price than the Madras sort, on account of its being a much stronger dye.

3. Madras Turmeric.—This is the most showy of all the kinds of turmeric. It consists principally of large long tubers (curcuma longa, Fig. 228), but mixed with transverse segments of round tubers (c. rotunda, Fig. 229). Externally, the tubers are marked by longitudinal wrinkles, the surface of which is rubbed and bright yellow; internally, the colour is that of a fresh-fractured surface of gamboge.

4. Malabar Turmeric; Bombay Turmeric.—This sort is not constantly found in the market. It consists principally of long tubers (c. longa, Fig. 230); the round tubers (c. rotunda) being few and of very inferior quality. This sort of turmeric is smaller and more shrivelled than the Madras sort, but otherwise somewhat resembles it.

5. Java Turmeric.—Not frequently found in the English market. In a general way, it may be said to resemble the China sort. It consists of both round and long tubers (c. rotunda et longa, Fig. 231), but chiefly the latter. They have a greenish-yellow hue.

Under the name of bulbs of Batavian turmeric, I have received a sample of round tubers (Fig. 232) said to be from Java. Dr. Th. Martius notices this sort as having been brought for many years from Batavia, and adds that it contains much colouring matter, and is probably the produce of Curcuma viridiflora.

Composition.—Two analyses of turmeric have been made; one by John,1 and a second by MM. Vogel and Pelletier.2

**Curcumin. Yellow Colouring Matter.**—Is obtained, mixed with some volatile oil and chlorid of calcium, by digesting the alcoholic extract of turmeric in ether, and evaporating the ethereal tincture to dryness. In the mass, curcumin is brownish-yellow, but when powdered it becomes full yellow. It is tasteless, colourless, almost insoluble in water, but readily soluble in alcohol and ether. These properties show that it is of a resinous nature. The alkalies colour it reddish-brown, and readily dissolve it. The alcoholic solution, evaporated with boracic acid, becomes red. Hydrochloric acid, also, reddens it. The alcoholic solution of curcumin produces coloured precipitates with several salts, as acetate of lead and nitrate of silver.

**Chemical Characteristics.**—The alkalies change an infusion of turmeric, or turmeric paper, to reddish-brown. A similar alteration of colour occurs when turmeric paper is exposed to the vapour of hydrochloric acid gas, or is touched with oil of vitriol. If, to tincture of turmeric, boracic acid be added, and the mixture be evaporated to dryness, an orange-red residue is obtained, whereas, without the acid, the residue is yellow. By this test the yellow colouring matter of turmeric can be distinguished from that of rhubarb (see Rheum). Sulphate of copper causes a yellowish precipitate with an infusion of turmeric. A similar effect is produced by sesquichloride of iron.

**Physiological Effects.**—Are those of a mild aromatic stimulant (see vol. i. p. 253). The colouring matter becomes absorbed, and communicates a yellow tinge to the urine. According to Mr. Gibson, the colouring matter of turmeric is somewhat changed by the digestive organs; for the stools of animals fed with this root were green, whilst both logwood and madder exhibited their respective hues after passing through the intestines.

**Uses.**—Employed as a condiment, colouring ingredient, and test. It is a constituent of the well-known curry powder and curry paste, and of many other articles of Indian cookery. Formerly, it had some reputation in hepatic and other visceral diseases, and especially in jaundice.

As a test, it is used to detect the presence of free alkalies, which change its yellow colour to a reddish-brown.

But alkaline earths and the alkaline carbonates, borates, and sulphures, as well as boracic and hydrochloric acids, change the colour of turmeric from yellow to brown. Though not a very delicate test, it is often a very useful one.

1. **Tinctura Curcumee; Tincture of Turmeric.**—Prepared by digesting one part of bruised Turmeric in six parts of Proof Spirit. Employed for the preparation of turmeric paper. Diluted with water, it yields a slightly turbid yellow liquid, which is sometimes used in the class-room as a test for alkalies, &c.

2. **Charta Curcumee; Charta exploratoria flavae; Turmeric Paper.**—Prepared with white, bibulous, or unsized paper, which is to be brushed over with, or soaked in, tincture of turmeric, and dried in the air, the access of alkaline and acid fumes being prevented. Mr. Faraday directs it to be prepared with a decoction of turmeric (prepared by boiling one ounce of the coarsely-powdered turmeric in ten or twelve ounces of water, straining through a cloth, and allowing the fluid to settle for a minute or two). Turmeric paper is employed as a test for alkalies, &c., which render it reddish or brownish.

---

3 *Chemical Manipulation.*
78. CURCUMA ANGUSTIFOLIA, Roxburgh.—THE NARROW-LAED TURMERIC.

Sex. Syst. Monandria, Monogymin.
(Fecula tuberis. East Indian Arrow-root, Offic.)

History.—This plant was found by H. T. Colebrook, Esq., in the forests extending from the banks of the Sona to Nagpore, and was by him introduced into the Botanic garden at Calcutta.¹

Sp. Char.—Bulb oblong, with pale, oblong, pendulous tubers only. Leaves stalked, narrow lanceolate. Flowers longer than the bracts.

Hab.—East Indies; from the banks of the Sona to Nagpore (Roxburgh). Also in abundance on the Malabar coast (Ainslie).

Extraction of the Fecula.—From the tubers of several species of Curcuma is obtained, in the East Indies, a fecula called tikor.

According to Dr. Roxburgh,² the biennial roots of the genus Curcuma consist of what he calls bulbs, tubers, and fibres. The bulbs are formed during the first year, and support the aerial parts of the plants; hence they may be termed phyllophorous receptacles. From these bulbs issue the palmate tubers, and chiefly the fibres or genuine roots; the latter issuing from the lower part of the bulbs. Some of the fibres end in a single oblong, pearl-coloured, solid tuber. From these tubers, and from no other parts, the natives of various parts of India obtain starch.

At Bhagulpore this is procured from C. leucorrhiza. "The root is dug up, and rubbed on a stone, or beat in a mortar, and afterwards rubbed in water with the hand, and strained through a cloth; the fecula having subsided, the water is poured off, and the Tikor (fecula) dried for use."³

At Travancore, and also, according to Bennett,⁴ at Bombay, from the C. angustifolia. "So much of it has been made of late years on the Malabar coast, where the plant grows in abundance, that it has become a considerable object in trade, and is much prized in England."⁵

C. rubescens is another species which also yields the fecula called tikor.

Description.—Curcuma starch (amyllum curcuma) or tikor is imported from the East Indies under the name of East India arrow-root. But as this name is also applied to the starch of Maranta arundinacea, cultivated in the East Indies, I have thought it advisable to distinguish it by the name of "Curcuma starch."⁶

Two kinds of Curcuma starch are imported from Calcutta; one white, the other buff-coloured.

a. White tikor, or curcuma starch, or white East Indian arrow-root, is a fine white powder, readily distinguishable, both by the eye and the touch, from West Indian arrow-root. To the eye it somewhat resembles a finely-powdered salt (as bicarbonate of soda or Rochelle salt). When pinched or pressed by the fingers, it wants the firmness so characteristic of West Indian arrow-root, and it does not crepitate to the same extent when rubbed between the fingers.

Examined by the microscope, the particles of this starch are found to be transparent flattened disks of about the 331/3d of an inch in thickness.⁷ Their shape is ovate, or oblong-ovate, with a very short neck or nipple-like projection at one extremity, where is situated the part called the hilum. The largest are about 1/370th of an inch in length, and 1/126th of an inch in breadth.⁸

¹ Roxburgh, Fl. Indica, vol. i. p. 31.
⁵ Ainslie, Mon. Indica, vol. i. p. 19, 1826.
⁶ Ceylon and its Capabilities, p. 151.
⁷ The following measurements, in parts of an English inch, of the particles of East India arrow-root, were made for me by Mr. George Jackson:—
On account of their flatness they have but little lateral shading, except when viewed edgewise. The hilum or nucleus is placed at the narrow extremity—is circular, very small, and not very distinct. The rings (or rather portions of rings) are seen both on the flat surface and on the edges; they are numerous, close, and very fine.

3. Buff-coloured tiko, or curcuma starch; pale buff-coloured East Indian arrow-root.—In the form of powder, or of pulverulent masses, which are dirty or buffy white. Paddy husks, woody fibre, and various impurities, are intermixed.

To the microscope both kinds present the same appearance, from which it is probable that they are obtained from the same plant, but with unequal degrees of care. The particles of East Indian arrow-root are very unequal in size, but on the average are larger than those of West Indian arrow-root.

Composition.—Not ascertained, but doubtless analogous to that of other starches, viz. C\(^{14}\)H\(^{26}\)O\(^{10}\).

Effects and Uses.—Analogous to those of the West Indian starch. Its commercial value, however, is much below that of the latter. At Travancore, it forms a large portion of the diet of the inhabitants (Roxburgh).

79. Curcuma Zedoaria, Roxburgh.—Round Zedoary.

Sex. Syst. Monandria, Monogyia. (Tubera.)

Dr. Roxburgh gave some of the dried roots of this plant to Sir Joseph Banks, who ascertained that they agreed well with the zedoaria rotunda of the shops.\(^1\)

1. Zedoaria rotunda.—The zedoary root (radix zedoaria) now found in the shops of English druggists is the round zedoary (zedoaria rotunda) of pharmacological writers. It occurs in segments (halves, quarters, or flat sections) of a roundish or ovate tuber. The external portion of the tuber is marked by the remains, membranes, and fibres, and is of a pale brownish-gray or whitish appearance. When cut, it presents a yellowish marbled appearance, not very dissimilar to the cut surface of rhubarb. It has a warm, aromatic, bitter taste, and an aromatic odour. It has been analyzed by Buchet\(^2\) and by Morin.\(^3\) Its constituents, according to the latter chemist, are—volatile oil, resin, gum, starch, woody fibre, vegeto-animal matter (?), osmazone (?), free acetic acid, acetate of potash, sulphar, and in the ashes carbonate and sulphate of potash, chloride of potassium, phosphate of lime, alumina, silica, oxides of iron and manganese. It possesses aromatic and tonic properties. It is less heating than ginger and galangal, and is more analogous to turmeric.

2. Zedoaria longa.—The root called long zedoary (zedoaria longa) is no longer found in the shops of English druggists. It is in pieces scarcely so long and wide as the little finger. Its chemical and medicinal properties resemble those of round zedoary. It is, perhaps, the zerumbet root (radix zerumbet), for a piece of which I am indebted to Dr. Royle. It is very similar in shape to a curved or arched piece of long turmeric. Its colour is yellowish-gray.

The plant which yields long zedoary has not been satisfactorily ascertained; but it is probably the Curcuma Zerumbet of Roxburgh, who states that the zerumbet or kuchoor of the native druggists of Calcutta are the roots of this species of Curcuma, and that they are principally obtained from Chittagong. He also adds, that he sent the sliced and dried bulbous and palmate tuberous roots to Sir J. Banks, who ascertained that they were the real zedoaria of our Materia Medica, and that the root of C. Zedoaria was the zedoaria rotunda of the shops.

3. Zedoaria lutea.—The turmeric coloured zedoary of Ainslie,\(^4\) the yellow zedoary (zedoaire jaune) of Guibourt, is probably the cassumunar root (radix cassumunar) of English druggists (see ante, p. 234).

80. AMOMUM CARDAMOMUM, Linn.—THE CLUSTER OR ROUND CARDAMOM.

**Sex. Syst. Monandria, Monogynia.**
(Semina.)

**History.**—The fruit of this plant is the σαφων of Dioscorides, the Amomi uva of Pliny. 3

**Botany. Gen. Char.**—Inner limb of the corolla one-lipped. Filament dilated beyond the anther, with an entire or lobed crest. Capsule often berried, 3-celled, 3-valved. 'Seeds numerous, arillate.—Herbaceous perennials, with articulated creeping rhizomes. Leaves in 2 rows, membranous, with their sheaths split. Inflorescence spiked, loosely imbricated, radical (Blume). 4

**Sp. Char.**—Leaves with short petioles, lanceolate. Spikes half immersed in the earth, loosely imbricated with villous, lanceolate, acute, 1-flowered bracts. Lip, with the interior margin, 3-lobed. Crest 3-lobed ( Roxburgh).

**Hab.**—Sumatra, Java, and other islands eastward to the Bay of Bengal.

**Description.**—The fruit of this plant is the round cardamom (cardamomum rotundum) of the shops. It varies in size from that of a black currant to that of a cherry. It is roundish or roundish-ovate, with three convex rounded sides or lobes, more or less striated longitudinally, yellowish or brownish-white, sometimes with a red tint, and when examined by a pocket lens shows the remains of hairs, the greater part of which have probably been rubbed off. The seeds are brown, angular, cuneiform, shrivelled, with an aromatic, camphoraceous flavour. The fruits in their native clusters or spikes (constituting the Amomum racemosum) are rarely met with; a fine sample is in the Slovanian collection of the British Museum.

**Composition.**—It has not been analyzed. Its constituents are probably analogous to those of the Malabar cardamom (Elettaria Cardamomum).

**Effects and Uses.**—Similar to those of the Malabar cardamom. Round cardamoms are rarely employed in this country. They are officinal in the French Codex, and are principally consumed in the southern parts of Europe. The seeds are directed to be used by the Dublin Pharmacopoeia, but I presume those of the Elettaria Cardamomum are intended.

81. AMOMUM GRANUM PARADISI, Afzelius; et A. MELEGUETA, Roscoe.

**Sex. Syst. Monandria, Monogynia.**
(Semina.)

**History.**—The term "Malagueta* pepper" has been applied to the fruit or seeds of several zingiberaceous plants, 5 as well as to the pimento or allspice. 6 It is usually considered to be synonymous with the terms "grains of paradise," and "Guinea grains."

---

1 Lib. i. cap. xiv.
3 This word is variously spelt Malagueta, Malagueta, Melegueta, Melgoleta, Melgetta, &c. Several etymologies of it have been given: some say the seeds have been so called in consequence of their resemblance to Turkey millet, termed by the Italiano melita or meleta. Savary says the term is derived from melita gente, the designation applied by the Portuguese to the people of the coast yielding the seeds. Another derivation (suggested to me by Mr. R. Thomson, of the London Institution) is Meli (also written Melli and Meli), a kingdom of Nigrizia; and gitti (or gitter), a Portuguese name for pepper. Barbou says the Portuguese word malagueta is from the native name for the pepper, emanegita.
5 See Ortega, Historia natural de la Malaguetia, o Pimienta de Taxasco, Madrid, 1780.
Malagueta pepper is said to have been known in Italy before the discovery of the Guinea coast by the Portuguese in the 16th century. It was brought by the Moors, who used to cross the great region of Madingha and the deserts of Lybia, and carry it to Mundi Barca (or Monte da Barca), a port in the Mediterranean. The Italians, not knowing the place of its birth, as it is so precious a spice, called it *grana paradisi.*

**Botany.**—The botanical history of these seeds is still involved in some obscurity.

Two plants, one called by Afzelius and Smith *Amomum Granum Paradisi,* the other termed by Roscoe *A. Melegueta,* have been said to produce them. But some doubt exists whether these be identical or distinct species. In 1847, in a paper on Roscoe's *A. Melegueta,* I mentioned that there were slight differences in the appearance of the seeds of the two plants. Since then, I have ascertained that there are two sorts of grains of paradise in the market, and that these are brought from different parts of the African coast, are readily distinguished from each other in trade, and are of unequal commercial value: one of these is identical with the seeds of *A. Granum Paradisi* of Afzelius and Smith, the other with those of *A. Melegueta* of Roscoe.

**Rhizome** perennial, woolly, creeping horizontally. **Stems** erect, simple, slender, three feet high, leafy, but destitute of flowers. **Leaves** numerous, crowded, two-ranked, alternate, a span long and an inch broad, lanceolate, or slightly ovate, with a long taper point, entire, smooth, single-ribbed, striated with innumerable oblique veins. Their flavour is slightly aromatic, after having been dried 20 years. **Foot-stalks** sheathing, linear, very long, smooth, striated. **Flower-stalks** radical, solitary, an inch or two in length, ascending, clothed with numerous, close, sheathing **bracts,** all abrupt, ribbed, somewhat hairy and fringed; the lower ones very short; the upper gradually much larger. Of the parts of the flower nothing could be made out in Sir J. Smith's specimens.

[According to Afzelius, the flowers are large and white, and formed like those of *A. excapum,* Sims.] **Capsule** an inch and a half long, half an inch in diameter, oblong, bluntly triangular, acutely ovate, beaked, of a dark reddish brown, ribbed, coriaceous, tough, with minute deciduous bristly hairs. When broken, it is very powerfully aromatic, even after being kept 20 years, with a peculiar pepper-like flavour, rather too strong to be agreeable. **Seeds** numerous, enveloped in membranes formed of the dried pulp, roundish or somewhat angular, of a shining golden-brown, minutely rough or granulated, extremely hot and acrid (Smith).

**Stem** erect, six feet high. **Leaves** two-ranked, subasessile, narrow-lanceolate. **Scape** radical, covered at the base with about seven imbricated, ovate, concave, pointed, and somewhat cuspulate **bracts.** **Calyx** cylindrical, of one leaf, green, spotted with red. **Flowers** cylindrical, expanding in a double border; outer border in three sections; the middle section largest, ovate, the two others linear and opposite; inner lip very large, broad-ovate, crenate, pale yellow at the base, crimson at the margin. **Filament** strong, erect, clasping, terminating in three lobes, middle lobe erect and bifid, the other two pointed and recurved; a pair of hornlets on the filament, near the base of the lip. **Anther** in two lobes, seated in front of the filament, a little below the apex, bright yellow. **Style** erect, tubular, expanding into a dilated **stigma** or cup, supported at the base.

**Amomum Granum Paradisi,** Smith.

(Natural size. From a specimen in Smith's herbarium in the collection of the Linnean Society.)
by two linear processes, about an inch in length, and one-eighth of an inch in breadth, by much the largest specimen of this part observable in any scitamineous plant.

Fig. 235.

**Leaves and Flower of Amomum Melegueta, Roscoe.**

| a. Stem and leaves. | d. Interior limb of corolla or lip. |
| b. Entire flower and floral bracts. | e. Filament, anther, stigma, style, and ovary. |
| c. Exterior limb of corolla. | f. Style and barren anthers (germinal processes). |

**Capsule** cylindrical, coriaceous, six inches long, yellow, spotted with orange, supported at the base by the large ovate, concave, cuspidate bracts, and containing a columnella or receptacle about four inches long, covered with seeds beautifully arranged, arilled, and imbedded in a tomentose substance. Seeds angular, light brown, with a highly aromatic and grateful flavour (Roscoe).

**DESCRIPTION. a. Of the dried fruits.**—I have met with two kinds of dried fruits whose seeds bear the name of grains of paradise or Guinea grains.

1. **Grains of Paradise Fruit** (Fig. 240).—These are oval or oval-oblong capsules, somewhat reddish-brown, and wrinkled longitudinally. Their length (exclusive of stalk and beak) rarely exceeds 1½ inches; and their diameter is about ½ an inch. The seeds agree with the grains of paradise brought from Cape Palmas and Sierra Leone. I am indebted to Dr. Daniell for specimens gathered from the high lands on the right of the River Congo. Some of them are strung on a cord; the usual form in which they are sold in Africa.—These fruits appear to me to agree with the Grain of Paradise Amomum described by Afzelius and Smith.
Fig. 236. Entire fruit preserved wet.
Fig. 237. Transverse section of ditto.

Fruit of Amomum Melegueta, Roscoe.

Fig. 238. Entire fruit dried.
Fig. 239. Seeds of ditto.
2. Malagueta Pepper Fruit (Fig. 241).—These fruits are larger than the preceding, and more ovate. Exclusive of beak and stalk they are two inches long, and one inch in diameter. They are ovate or ovate-oblong, coriaceous, wrinkled as if shrivelled, yellowish-brown. The seeds are identical with those sold in the shops as grains of paradise or Guinea grains. From the large size of this fruit, I suspect it may be the produce of Roscoe's A. Melegueta.

3. Of the seeds.—The seeds, called in the shops grains of paradise (grana paradisi) or Guinea grains (grana guineensia), are roundish or ovate, frequently bluntly angular, and somewhat cuneiform; shining golden brown; minutely rough, from small warts and wrinkles; internally white. Their taste is aromatic, and vehemently hot or peppery; when crushed and rubbed between the fingers, their odour is feebly aromatic. Their greatest diameter rarely exceeds 1/4 line. The acrid taste resides in the seed coats.

Two sorts are distinguished by the importers:

1. Guinea grains from Acra.—These are somewhat larger, plumper, and more warty than the ordinary sort. On the umbilicus of the seeds there is a short, conical, projecting tuft of pale-coloured fibres. This sort fetches a somewhat higher price than the next sort. The seeds agree precisely in appearance with those obtained from Roscoe's A. Melegueta.

2. Guinea grains from Cape Palmas and Sierra Leone.—Smaller and smoother than the preceding. They are devoid of the projecting fibrous tuft on the umbilicus. Being somewhat cheaper than the foregoing sort, they form the ordinary grains of paradise of the shops. They are perhaps the produce of Afzelius and Smith's A. Granum Paradisi.

Commerce.—Grains of paradise are imported in casks, barrels, and puncheons, from the coast of Guinea. The quantities on which duty was paid during six years are as follows (Trade List):

<table>

<td>18,636 lbs.</td>
</tr>
</tbody>
</table>
"Extract or preparation of 'Guinea grains'" was formerly imported.  

The heavy duty formerly imposed on grains of paradise was intended to act as a prohibition of their use.

COMPOSITION.—Grains of paradise were analyzed in 1811 by Willert,

who obtained the following results: Volatile oil 0.52, acrid resin 3.40, extractive 1.27, tragacanthin and woody fibre 82.8 [± water and loss 12.01].

1. The Volatile Oil has a light yellow colour, a camphoraceous smell, and a hot penetrating taste.
2. The Resin is brown, soft, odourless, and has an acrid burning taste.

PHYSIOLOGICAL EFFECTS.—Analogous to those of pepper. A very erroneous notion prevails that these seeds are highly injurious.

USES.—Rarely employed as an aromatic. Esteemed in Africa as the most wholesome of spices, and generally used by the natives to season their food.

Its principal consumption is in veterinary medicine, and to give an artificial strength to spirits, wine, beer, and vinegar.

By 56 Geo. III. c. 58, no brewer or dealer in beer shall have in his possession or use grains of paradise, under a penalty of £200 for each offence; and no druggist shall sell it to a brewer, under a penalty of £500 for each offence.

82. Amomum maximum, Roxburgh.—The Great-winged Amomum.

(Fructus: Java Cardamom, offic.)

HISTORY.—This plant was first described by Roxburgh.

BOTANY. Gen. Char.—Vide Amomum Cardamonum.

(Roxburgh.)

The capsule is "almost globular, size of a gooseberry, 3-celled, 3-valved, ornamented with nine [seven to thirteen, Blume] firm, short, ragged (when old and dry), membranaceous wings. The seeds possess a warm, pungent, aromatic taste, not unlike that of cardamoms, but by no means so grateful." (Roxburgh.) The Nepal cardamom, described by Dr. Hamilton, appears to be identical with the Java cardamom. Dr. Hamilton says, the plant yielding it is "a species of Amomum, as that genus is defined by Dr. Roxburgh, and differs very much from the cardamom of Malabar."

Hab.—The Malay Islands (Roxburgh); Java (Blume). Cultivated in the mountainous parts of Nepal, where it is propagated by cuttings of the root [rhizome]; the plants yield in three years, and afterwards give an annual crop (Hamilton).

DESCRIPTION.—The fruit of this plant is known in commerce by various names; such as greater Java cardamoms (cardamomi majorum-Javanese, Th. Martius; Java cardamoms, offic.; Nepal cardamoms, dest elachi [i.e. country cardamoms] of Hindustan; Hamilton; the bura elachi [i.e. great cardamoms] of Saharanpore—the Bengal cardamoms of the Calcutta market, Royale; cardamome aïd de Java and cardamome fausse maniguette, Guibourt) are oval or oval-oblong, frequently somewhat ovate, three-valved, from eight to fifteen lines long, and from four to eight lines broad, usually flattened on one side, convex on the other, occasionally curved, sometimes imperfectly three-lobed, and resembling in their form the pericarp of the cocom-nut (Fig. 242). Their colour is dirty grayish-brown. They have a

1. Fremlin, Digested Abridgment of the Laws of the Customs, 1819.
6. An Account of the Kingdom of Nepal, ed. 1819.
VEGETABLES.—NAT. ORD. ZINGIBERACEAE.

course, fibrous, aged appearance, are strongly ribbed, and when soaked in hot water (Fig. 243) become most globular, and present from nine to thirteen ragged, membranous wings, which occupy the upper half or three-fourths of the capsule, and are scarcely perceptible in the dried state of the pericarp. By the possession of wings, these cardamoms are distinguished from all others of commerce, and hence might be called the winged cardamoms. Occasionally the foot-stalk is attached, with, now and then, portions of brown, membranous, imbricated scales, as long as the fruit. At the opposite or winged extremity of the capsule are frequently the fibrous remains of the calyx. Seeds (Fig. 244) somewhat larger than grains of paradise, dull, dirty brown, with a shallow groove on one side, internally white; taste and odour feebly aromatic. One hundred parts of the fruit consist, according to Th. Martius, of seventy parts seeds, and thirty parts pericarpal coats. They are imported in bags.

**Composition.**—Analogous probably to that of the Malabar cardamom, except in the quantity of volatile oil which it yields; for Martius procured only four scruples of it from a pound of the fruit. The oil obtained was white and thickish.

**Effects and Uses.**—Java cardamoms are not used here. They are of inferior quality, and when brought to this country are usually sold in bond for continental use. In 1839, a quantity of them was sold at seven-pence per lb.

88. **Amomum Korarima.**—The Korarima Cardamom.

The fruit of this plant is the *cardamomum majus* of Valerius Cordus, of Matthiolus, Geoffroy, Smith, and Geiger. In Dr. Burgess's Collection of Materia Medica at the College of Physicians, there are several fine specimens marked "*Cardamomum maximum Matthioli*" (Fig. 245.)

Under the name of Korarima, or *Gurâgîe* spice, I have received specimens of the same fruit, which had been brought from Abyssinia by Major Harris's embassy, by Dr. Beke, and by Mr. Charles Johnston (Fig. 246).

In former editions of this work, I followed Sir J. E. Smith in considering this fruit to be identical with the *Amomum Madagascarriense* of Lamarck, and the *A. augustifolium* of Sonnerat. As there is some reason to doubt the propriety of this proceeding, I have considered it advisable to designate the plant provisionally the "*Amomum Korarima*;" the word Korarima (pronounced in English Korâhrēēma), being the Galla name for the fruit which in Arabic is called Kheil or Kheî.

The capsule is ovate, pointed, flattened on one side, striated, with a broad circular umbilicus or scar at the bottom, around which is an elevated, notched, and corrugated margin. Some authors who have mistaken the base of the capsule for its summit, have compared the shape to that of a fig.

Some of the fruits which I received from Abyssinia had been perforated and strung upon a cord (Fig. 246), probably for the purpose of hanging them to dry. Dr. Beke thinks that the pierced or perforated fruits are those which have been gathered before they were perfectly ripe.

The seeds (Fig. 247) are rather larger than grains of paradise, roundish or somewhat angular, abrupt at the base, olive-brown, with an aromatic flavour analogous to that of the Malabar cardamom, but totally devoid of the vehemently hot acrid taste of the grains of paradise.

The Korarima is brought to the market of Bâsso, in southern Abyssinia, from Tûmbe, (known among the native merchants as the "country of the Korarima") somewhere about 63° N. lat. and 33° E. long. It is carried to Massowâh, the port of northern Abyssinia on the Red Sea,

---

1. Pharmacognosia.
and exported from thence to India. Dr. Rüppell was informed that the annual export is of the value of one thousand dollars (about £200 sterling). Although it is not impossible that the same fruit may grow in Madagascar, yet it is highly improbable that the Kararima of Abyssinia is the produce of Madagascar.1

At Bâso, Dr. Beke purchased it at the rate of forty for one penny sterling. The seeds are aromatic, and possess properties similar to, but more feeble than, those of the Malabar cardamom. In Abyssinia, they are used as a condiment and in medicine.

84. Amomum citratum.

Cardamomum majus.—In Dr. Burgess’s collection at the College of Physicians is a capsule (in a bad state of preservation) marked “Cardamomum majus.” It has a fibrous tuft at one extremity, and is much split at the other. The seeds are angular, oblong, larger than those of Malabar cardamoms, shining brownish-yellow, and have a large concave depression (hilum) at one extremity. They have a warm aromatic flavour, somewhat analogous to that of the oil of lemongrass. When crushed, they evolve the odour of this oil. Hence I have given them the specific name “citratum,” as by this character they are readily distinguished from all other seeds of this order with which I am acquainted.

I have found the same fruits in the Sloanian collection of the British Museum. They are tied together in bunches. One sample is unnamed; another is marked in the catalogue “12057. Grana Paradisi.”

I have met with the same fruits in a collection at Apothecaries’ Hall; and I am indebted to Mr. Warrington for the specimen from which Fig. 248 was taken. The capsules are tied together in bunches, as shown in the accompanying figure.

85. Amomum Clusii, Smith.—Clusius’s Cardamom.

Fructus, tiv., Clusius, Exotic. lib. ii. cap. xv. pp. 37 and 38; Gravis paradysi sive Malgegeta of&inia fructus, Banjin, Pinax. p. 413; Amomum Clusii, or Long-seeded Amomum, Smith, Rees’s Cyclop. vol. xxxix., Addenda.—Capsule ovate, pointed, slightly triangular, cartilaginous, striated, smooth, yellowish [reddish, Smith] brown. The seeds have scarcely any flavour, are oblong or ovate, inclining to cylindrical, dark-brown, highly polished, as if varnished; with a pale yellowish-brown, corrugated, and notched margin surrounding the scar.

On comparing my specimen (Fig. 249), which was given to me by a druggist, with the one marked A. Clusii, in Sir J. E. Smith’s collection of fruits in the possession of the Linnean Society, I find the seeds of the latter are somewhat longer, and rather more cylindrical; in other respects, the two specimens agree.

I have subsequently received, from Dr. T. W. C. Martius, specimens of a fruit marked “Cardamomum maximum von Amomum Clusii?” The capsules are somewhat plumper, but in other respects they agree with the preceding. I gave one of them to Professor Gilbourt, who has published a figure of it.2

I have received from Dr. Daniell specimens of an Amomum which greatly resembles, if it be not identical with, A. Clusii. The capsules (Figs. 250 and 251), however, are narrower and more tapering than the latter. The seeds (Fig. 252) are obvate, highly polished, smooth, and

---

2 Hist. Nat. des Droge. 4ème édit. t. ii. p. 229, fig. 120, 1810.

dark brown. Are these capsules the produce of A. Afzelii? Dr. Daniell\(^1\) says they grow in the thickets at Attaphaph, on the gold and slave coasts, and plentifully on the outskirts of Clarence and Fernando Po, where they are known under the name of "bastard Melligetta." The seeds are contained in a soft acidulous pulp of a pleasant flavour, which the natives use in lengthened expeditions to allay thirst, and also as an adjunct to allay the irritative effects of cathartic and other medicines.

86. Amomum macrospermum, Smith.—Large-seeded Guinea Amomum.

(Semina.)

\(^1\) Sketches of the Medical Topography of the Gulf of Guinea, pp. 111 and 112, 1849.

Zingiber Melegueta, Gaertner de Fructib, vol. i. p. 34, pl. xii. fig. 1; Fructus Cajeputi, Trew, Commercium Litterarium, ann. 1737, Norimberga, p. 129, tab. 1, figs. 7-11; also Herb. Blackwellianum emend. et auctum, vol. iii. cent. vi. tab. 584, figs. 9–13, Norimb. 1773.—Native of Sierra Leone.

The capsule (fructus cajeputi, Trew; cardamomum bandaeae, T. W. C. Martius; grand cardamone de Gaertner, Guibourt; mabooboo of the natives of Sierra Leone),\(^2\) is ovate, pointed, somewhat striated, about two inches long, and six lines broad, with a corrugated beak.

\(^2\) Sir J. E. Smith (Rees's Cyclop. Suppl.) states, on the authority of Afzelius, that the African name is "Mabooboo." But Nyberg (Remedia Guineensia, Upsal, 1818) says that the name "Mabuhu" is applied to a species which he calls Amomum latifolium, whose seeds, in size, shape, and colour, agree with grape seeds.
The seeds (semina cajuputi; Trew) are ovate, or nearly globular, or somewhat oblong, variously angular, scarcely larger than grains of paradise, smooth, polished, greenish-gray, or lead-coloured, with a strong umbilicated scar at their base, with a whitish or pale-yellowish margin; flavour slightly aromatic. Smith says that Gaertner's figure represents them scarcely half large enough. This statement, however, does not apply to the seeds of my specimens.

The seeds yield, by distillation, a volatile oil. Cartheuser obtained from half a pound of them a drachm and a half of a pale-yellowish, aromatic, camphoraceous oil, resembling, but less fragrant and penetrating than, cajuput oil. Trew erroneously supposed that these seeds were the source of the cajuput oil of commerce, and hence have arisen the erroneous denominations of "fructus et semina cajuputi," applied to the fruit and seeds of this species.

The seeds are aromatic, but are much inferior to those of the Malabar cardamom.

I have received from Dr. Daniell specimens of the fruit of this or some closely allied species growing at Gambia and Cape St. Mary. One of the specimens consists of a stalk five inches long, supporting two capsules, and clothed with bracts. The seeds are angular, and lead-coloured. Dr. Daniell tells me that the natives of Africa suck the acidulous pulp of the fruit.

87. Amomum globosum, Loureiro?

(Semina.)

Fig. 253. Fig. 254.

(From a specimen in the Sloanian collection.) (Banda cardamom of Martius and its seeds.)

Amomum macropermum.

88. Amomum villosum, Loureiro?

(Semina.)

St. Xa mi, Chin., Loureiro.—Mountains of Cochinchina.

I am indebted to Professor Guibourt for the loan of this fruit, which he calls the round China cardamom (cardamome rond de la Chine), and from which the accompanying figure was taken.

Capsule thin, round, or oval. Seeds in globular masses, marked, on the surface opposed to the pericarp, by a linear depression or groove.

I have observed specimens in the Sloanian collection of the British Museum, and also in a collection of Chinese medicines at the College of Physicians.

This fruit may perhaps be the produce of Loureiro's Amomum globosum, the seeds of which he says are slightly calefacient and stomachic. They are frequently employed by medical practitioners in China and Cochinchina, and are useful in restraining abdominal pain, sickness, and diarrhoea.

On comparing Professor Guibourt's specimen with the fruit of Alpinia nutans (see p. 250) in Dr. Wallich's collection, in the possession of the Linnean Society, the two are scarcely distinguishable externally. The seeds, however, are quite dissimilar.

---

2. Professor Guibourt (Hist. Nat. des. Drag, 4ème ed. p. 219, fig. 119) has figured one of the specimens given to me by Dr. Martius; but he has erroneously stated that the figure was from a specimen in the Sloanian collection of the British Museum.
VEGETABLES.—NAT. ORD. ZINGIBERACEAE.

Capsules ovate, oblong, obtusely triangular. Seeds have no linear depression or groove as those of the preceding variety; and by the absence of this they may be readily distinguished from it; coherent in masses, which are 3-lobed, not quite globular. In my specimens, the perisarp is rugous, as if eroded; but, when examined by a magnifier, it is seen to be covered by asperities and the remains of fine downy hairs. The flavour of the seeds is aromatic and terebinthinate, but not powerful.

M. Guibourt thinks this fruit may perhaps be the produce of Annonum villumum of Loureiro, the oriental names of which, however, are very different to that on the specimen in the Paris Museum. Loureiro states that the seeds of A. villum are sub-cylindrical and stomachic, and are exported from the provinces of Quí-nhon and Phý-yeu, in Cochin China (where they grow spontaneously), to China, where they are largely used in medicine.

Black Cardamom, Guibourt.—I am indebted to M. Guibourt for a fruit which he calls the black cardamom of Gaertnert (cardamome noir de Gaertner), or the fruit of Zingiber nigrum, Gaertn. The capsule is larger than the short Malabar cardamoms, acuminate at its two extremities, and formed, as it were, of two obtusely-triangular pyramids joined base to base. The pericarp ash-brown, aromatic, but less so than the seeds. Seeds annular, brown, slightly aromatic, but devoid of the terebinthinate flavour.

Gaertnert states that his plant is the Alughas of the Ceylonese. But the black cardamom of Guibourt is certainly not Roxburgh’s Alpinia Alughas.

89. Alpinia Galanga, Linn.; A. chinensis, Roxoe (?); and A. nutans, Roxoe.

Sex. Syst. Monandria, Monogynia.
(Rhizoma.)

Two kinds of galangal root (radix galanga), a lesser and a greater, have long been known in medicine: to these Guibourt has added a third, which he calls light galanga. These three sorts are the produce of different parts of the East, and probably of different species of Alpinia.

1. Radix galangae majoris; greater or Java galangal root.—This is the root of the Alpinia Galanga, Linn. It is a coarser and larger root, with a feebler and somewhat different odour from that of the lesser galangal root. Although it occasionally comes to Europe, I cannot learn that it finds any use here.

2. Radix galangae minoris; lesser or Chinese galangal root.—This is the root of a plant growing in China, according to Guibourt, the Alpinia chinensis, Roxoe (Hellenia chinensis, Willd.). It may perhaps be Alpinia alba, which König calls galanga alba. It is brought to England from China either directly or by way of Singapore. It is the only sort usually kept by English druggists. It occurs in pieces which are as thick as the finger, seldom exceeding three inches in length, cylindrical or somewhat tuberous, often forked, sometimes slightly striated longitudinally, and marked with whitish circular rings. Externally its colour is dull reddish-brown; internally pale, reddish-white. Its odour is agreeably aromatic; its taste peppery and aromatic. It has been analyzed by Bucholz and by Morin. The former obtained volatile oil 0.5, acrid soft resin 4.9, extractive 9.7, gum 5.2, bassorin 4.15, woody fibre 21.6, water 12.3, loss 1.3. It is a warm and agreeable aromatic, and is sometimes administered in the form of infusion in dyspepsia. Its effects, uses, and doses are analogous to those of ginger. It is, however, rarely employed in England—its principal consumption being on the continent.

3. Radix galangae levis; galanga leger, Guibourt; light galangal root.—This variety, according to M. Guibourt, is characterized by its great lightness; its weight being not more than a third of that of the previous sort. Its epidermis is smooth and shining. It is, perhaps, the root of Alpinia nutans (Roxoe), which Dr. Roxburgh states is odorous, and is sometimes brought to England for galanga major.

2 Trompeter's Journal, xxv. 2, p. 3.
4 Journ. de Pharm. ix. p. 257.
90. Alpinia alba, Rosco.
(Semina.)

Hellenia alba, Willd.; Heritiera alba, Retz.; Langoue vulgar, Kœnig; Amomum medium, Loureiro, fl. Cochinch.—The latter gives Thao quo as the Cochinchina name, and Thao qua as the Chinese name of the plant.

Specimens of this fruit are in the Muséum d’Histoire Naturelle of Paris, where they are labelled tsao-quo. For my specimens, I am indebted to Professor Guibourt, who calls the fruit the ovoid China cardamom (cardamome ovoide de la Chine).

The-dried fruit is about the size and shape of a large nutmeg; it is ovoid, from ten to fourteen lines long, and from six to eight lines broad, rather rigid, striated longitudinally, yellowish-brown with a reddish tint [scarlet when recent, Kœnig]. Seeds numerous, very large, pyramidal, brown externally, flavour and odour terebinthinate; albumen white, embryo yellow.

Grows in the province of Yu-nan. The seeds are aromatic, and are used by the natives as a condiment. They are said to be useful in intermitents. Kœnig terms the plant galanga alba, and says it is much used among the Malays.

91. ELETTARIA CARDAMOMUM, Maton.—THE TRUE OR OFFICINAL CARDAMOM.

Alpinia Cardamomum, Roxb. L.—Renealmia Cardamomum, Retz.—Amomum Cardamomum, D. Sex. Syst. Monandria, Monogyinia. (Semen, L.—The fruit; Cardamoms, Ed.—The seeds, D.)

History.—A medicine, called Cardamom (καρδάμωμον), is mentioned by Hippocrates, 4 Theophrastus, 3 and Dioscorides, 8 the first of whom employed it in medicine. But it is now scarcely possible to determine what substance they referred to, as their notices of it are brief and imperfect; though I believe it to have been one of the fruits which we call cardamoms. Pliny 4 speaks of four kinds of cardamoms, but it is almost impossible to ascertain with any certainty what species he refers to.

Botany. Gen. Char.—The same as that of Amomum, but the tube of the corolla filiform, and the anther naked (Blume).

Rhizome with numerous fleshy fibres. Stems perennial, erect, smooth, jointed, enveloped in the spongy sheaths of the leaves; from six to nine feet high. Leaves subsessile on their sheaths, entire; length from one to two feet. Sheaths slightly villous, with a roundish ligula rising above the mouth. Scapes several (three or four) from the base of the stems, flexuose, jointed, branched, one to two feet long. Branches or racemes alternate, one from each joint of the scape, suberect, two or three inches long. Bracts solitary, oblong, smooth, membraneous, striated, sheathing, one at each joint of the scape. Flowers alternate, short-stalked, solitary at each joint of the racemes, opening in succession as the racemes lengthen. Calyx funnel-shaped, three-toothed at the mouth, about three-quarters of an inch long, finely striated, permanent. Tube of corolla slender, as long as the calyx; limb double, exterior of three oblong, concave, nearly equal, pale greenish-white divisions; inner lip obovate, much larger than the exterior divisions, somewhat curled at the margin, with the apex slightly three-lobed, marked chiefly in the centre with purple violet stripes. Filament short, erect; anther double emarginate. Ovary oval, smooth; style slender, stigma funnel-shaped. Capsule oval, somewhat three-sided,

1 Pages 205, 572, 603, 651, ed. Fœs.
2 Lib. i. cap. 5.
3 Hist. Pl. lib. xi. cap. vii.
size of a small nutmeg [1], three-celled, three-valved. 

*Seeds many, angular (Roxburgh).*

**Hab.**—Mountainous part of the coast of Malabar.

**Production.**—Cardamoms are produced naturally or by cultivation. Between Travancore and Madura they grow without cultivation, and also at certain places in the hills which form the lower part of the Ghauts in Cudutinada and other northern districts of Malayata. The cardamoms of the Wynaad, which are esteemed the best, are cultivated: the spots chosen for the cardamom farms are called *Ela-Kandy*, and are either level or gently sloping surfaces on the highest range of the Ghauts after passing the first declivity from their base. Before the commencement of the periodical rains, in June, the cultivators of the cardamom ascend the coldest and most shady sides of a woody mountain; a tree of uncommon size and weight is then sought after, the adjacent spot is cleared of weeds, and the tree felled close at its root. The earth, shaken and loosened by the force of the fallen tree, shoots forth young cardamom plants in about a month’s time. The quantity of cardamoms brought for sale at Malabar is about 120, or, according to another account, only 100 candies, from the following places:

<table>
<thead>
<tr>
<th>Wynaad</th>

</tbody>
</table>

The cardamoms of the Wynaad are shorter, fuller of seed, and whiter, than those of Malabar, and sell for 100 rupees a candy more. Those of Coorg have fewer fine grains, but they have also fewer black or light ones. The cardamoms of Serisi (western part of Soonda) are inferior to those of Coorg.

**Description.**—The fruit of the *Elettaria Cardamomum* constitutes the small, officinal Malabar cardamom (cardamoms, Ed.; *cardamomum minus*, Clusius, Matthiolus, Bontius, Geoffroy, Dale, Geiger, Th. Martius, and Guibourt; *cardamomum malabarensis*). It is an ovate oblong, obtusely triangular capsule, from three to ten lines long, rarely exceeding three lines in breadth; coriaceous, ribbed, grayish or brownish yellow. It contains many angular blackish or reddish-brown rugose seeds (*cardamomum, L.; cardamomum excorticatum*, Offic.), which are white internally, have a pleasant aromatic odour, and a warm, aromatic, agreeable taste. 100 parts of the fruit yield 74 parts of seeds and 26 parts of pericarpial coats.

Three varieties of Malabar cardamoms are distinguished in commerce; viz. *shorts, short-long*, and *long-long*. The two latter differ from each other in size merely.

a. **Shorts.** Malabar cardamoms, properly so called; Petit cardamome (Guibourt); ? Wynaad cardamom (Hamilton); Prima species Elettari planae rotunda et albicans (Rheede). From three to six lines long, and from two to three lines broad; more coarsely ribbed, and of a browner colour, than the other varieties. This is the most esteemed variety.

b. **Short-long.** Secunda species Elettari oblongior sed vilitor (Rheede).—Differ from the third variety in being somewhat shorter and less acuminate.

c. **Long-long.** Moyen cardamome (Guib.): Tertia species Elettari viliissima et planae acuminata (Rheede).—From seven lines to an inch long, and from two to three lines broad:

7 Th. Martius, *Pharmakogn.*
8 Rheede, pars xi. tab. 4, 5, and 6.
elganted, somewhat acuminated. This, as well as the last variety, is paler and more finely ribbed than var. a. shorts. The seeds also are frequently paler (in some cases resembling those of the Ceylon cardamom) and more shrivelled.

The three sorts are brought from Bombay in chests. The shorts are usually the dearest, and fetch from 3d. to 6d. per lb. more than the longs. The long-long are seldom brought over. From Madras, only long cardamoms (usually short-long, rarely long-long) are brought: they are generally packed in bags, and are lighter by weight than the Bombay sort, and usually fetch 3d. per lb. less than the latter.

**Composition.**—The small cardamom was analyzed by Trommsdorff in 1834. He obtained the following results: Essential oil 4.6, fixed oil 10.4, a salt of potash (malate?) combined with a colouring matter 2.5, secund 3.0, nitrogenous mucilage with phospahte of lime 1.8, yellow colouring matter 0.4, and woody fibre 77.3.

1. **Volatile or Essential Oil of Cardamom.**—Is obtained from the seeds by distilling them with water. 50 lbs. of good short Malabar cardamoms yielded, at one operation, about 35 viss of oil for every 1b. of fruit. It is colourless, has an agreeable odour, and a strong, aromatic, burning taste. Its sp. gr. is 0.843. It is very soluble in alcohol, ether, oils (both fixed and volatile), and acetic acid. It is insoluble in potash-lye. By keeping, it becomes yellow, viscid, and loses its peculiar taste and smell. It then detumes with iodine, and takes fire when placed in contact with concentrated nitric acid. On this oil depend the odour, flavour, and aromatic qualities of the seeds. Its composition is analogous to that of oil of turpentine, being C<sub>9</sub>H<sub>8</sub>O.<br>

2. **Fixed Oil of Cardamom.**—Is insoluble in alcohol, ether, and the oils, both fixed and volatile. Nitric acid, assisted by heat, reddens it. It has some analogy to castor oil.

3. **Starch.**—Schleiden says that in these seeds he has a discovered amorphous paste-like starch in the cells.

**Physiological Effects.**—The effects of cardamoms are those of a very agreeable and grateful aromatic, devoid of all acridity.

**Uses.**—Cardamoms are employed partly on account of their flavour, and partly for their cordial and stimulant properties. They are rarely administered alone, but generally either as adjuvants or correctives of other medicines, especially of stimulants, tonics, and purgatives.

**Administration.**—Though cardamoms enter into a considerable number of pharmaceutical compounds, only two preparations derive their names from these seeds. They are the following:

1. **Tinctura Cardamomi, E. [U. S.]; Tincture of Cardamoms.**—(Cardamom seeds, bruised, 3i viss [3iv, U. S.]; Proof Spirit Oij [Diluted Alcohol, U. S.]. Macerate for seven days [fourteen, U. S.], and strain. “This tincture may be better prepared by the process of percolation in the same way with the tincture of capsicum, the seeds being first ground in a coffee-mill,” E.)—This compound is agreeably aromatic. It is used as an adjunct to cordial, tonic, and purgative mixtures. Dose 15j to 15j.

2. **Tintturca Cardamomi Composita, L. E. D. [U. S.]; Compound Tincture of Cardamoms.**—(Cardamom seeds bruised, Caraway seeds bruised, of each 3i viss [3is, D.]; Cochineal, powdered, 3i viss [3ij, D., 3j, E.]; Cinnamon, bruised, 3v [3j, D.]; Raisins [stoned] 3v [E.]; Proof Spirit Oij [Oijj, D.]. Macerate for seven [fourteen, D.] days, and filter. “This tincture may also be prepared by the method of percolation, if the solid materials be first beat together, moistened with a little spirit, and left thus for twelve hours before being put into the percolator,” Ed. The Dublin College omits the cochinical and raisins. [Take of Cardamom, bruised, six drachms; Caraway, bruised, two drachms; Cinnamon, bruised, five drachms; Raisins, deprived of their seeds, five ounces; Cochineal, bruised, a drachm; Diluted Alcohol two pints and a half. Macerate for fourteen days, express, and filter through paper, U. S.]—This tincture is used for the same purposes and in the same doses as the former preparation, over which it has the advantage of a more agreeable flavour. Moreover, its colour often renders it useful in prescribing.

2 Privee information.
92. **ELETTARIA MAJOR, Smith.—The Greater or Ceylon Elettaria.**

*Alpinia Gramum Paradisi,* Moon.
*(Fructus; Ceylon Cardamom, offic.)*

**History.**—The fruit of this plant was known to Clusius, who has noticed and figured it under the name of the *Cardamomum majus vulgare.*

**Botany.**—The flower has not yet been described, but the other parts of the plant are so similar to the corresponding parts of Elettaria Cardamomum, that I have felt no difficulty in referring this plant to the genus Elettaria. Sir James Edward Smith, who was acquainted with the fruit only, observes, "we are persuaded they must belong to the same genus as the Malabar Cardamom."

**Gen. Char.**—See *Elettaria Cardamomum,* p. 1142.

**Sp. Char.**—*Capsule* lanceolate oblong, acutely triangular, with flat sides. *Calyx* three-lobed (Smith).

**Rhizome** with numerous fibres. **Stem** erect, smooth, enveloped by leaf sheaths. **Leaves** sessile on their sheaths, silky beneath, acuminate; the shorter ones lanceolate, the larger ones oblong-lanceolate; breadth 2 to 3 inches, length not exceeding 1½ inches. **Skeaths** about half the length of the leaves, with a roundish ligula. **Scape** from the upper part of the rhizome, flexuose, jointed, 9 inches long, branched; the branches alternate, one from each joint of the scape, sub-erect, half an inch long, supporting two or three pedicels of about 3-10ths of an inch. **Bracts** solitary, sheathing at each joint of the scape, withered; partial ones, solitary, ovate, acute. **Flowers** not present. **Capsules** one or two on each branch of the scape, with the permanent calyx attached to them; their characters are described in the text.

The plant from which the above description has been drawn formed part of a collection made for me in Ceylon, by my much lamented friend and pupil, the late Mr. Frederick Saner, Assistant-Surgeon in Her Majesty's 61st regiment. He received it from Mr. Lear, Acting Superintendent of the Royal Botanic Gardens in Ceylon, whose letter, describing it as "*Alpinia [Amomum] Gramum paradisi,*" I have in my possession. I presume, therefore, that it is the plant which Mr. Moon, the former Superintendent of the Gardens, has described under the same name. The following facts favour this conclusion:

1. Mr. Moon states that its Sinigalese name is *Ensal,* a term which both Hermannus Burmannus gave as the native name for cardamon.

2. Mr. Moon states that it is cultivated at Candy. If the real grain of paradise plant were cultivated in Ceylon, it would be somewhat remarkable that its seeds are never exported. Now, I have carefully examined the list of exports from that island for several years, but the word grain of paradise never once occurs; and all the seeds imported into England under that name, I find, by the Custom-House returns, come from the western coast of Africa. On the other hand, the Ceylon cardamom comes, as its name indicates, from that island.

It is probable, I think, that the plant which yields the grains of paradise of European commerce does not grow in the East; and that writers who have stated otherwise have confounded it with the plant yielding Ceylon cardamom. But the term "grains of paradise" is so truly

---

2. For further details respecting the history of this cardamom, the reader is referred to a paper by the author, in the *Pharmaceutical Journal,* vol. ii. p. 384, 1842.
Cardamom is oblong, rarely cylindrical, permanent, three-lobed calyx; and at the other, the fruit-stalk, which is sometimes branched. The pericarp is coriaceous, tough, brownish or yellowish ash-coloured, three-celled. The seeds are angular, rugged, have a yellowish-red tinge, a fragrant and aromatic but peculiar odour, and a spicy flavour. The long diameter of the vitellus is parallel to that of the embryo. Th. Martius says that 100 parts of these fruits yield 71 parts of seeds, and 29 parts of pericarpial coats.

**Description.**—The Ceylon cardamom, or, as it is sometimes termed in English commerce, the wild cardamom (cardamomum zeylanicum; cardamomum medium, Math. and Geoff.; cardamomum majus, Bont. and Dale; cardamomum majus vulgar, Clusius; cardamomum majus officinarum, C. Bauhin; cardamomum longum, Th. Martius and Geiger; grande cardamome, Guib.), is a lanceolate-oblong capsule, acutely triangular, more or less curved with flat and ribbed sides, about an inch and a half long and one-third of an inch broad. At one extremity we frequently find the long, cylindrical, permanent, three-lobed calyx; and at the other, the fruit-stalk, which is sometimes branched. The pericarp is coriaceous, tough, brownish or yellowish ash-coloured, three-celled. The seeds are angular, rugged, have a yellowish-red tinge, a fragrant and aromatic but peculiar odour, and a spicy flavour. The long diameter of the vitellus is parallel to that of the embryo. Th. Martius says that 100 parts of these fruits yield 71 parts of seeds, and 29 parts of pericarpial coats.

**Composition, Effects, and Uses.**—Ceylon cardamoms have not been analyzed. Their constituents, as well as their effects and uses, are doubtless analogous to those of the Malabar cardamom. Their commercial value is about one-third that of the latter. They are chiefly used on the Continent.

**Order XVIII. Orchideae, R. Brown—Orchids.**

**Orchises, Jussieu.—Orchidaceae, Lindley.**

**Characters.**—Flowers irregular, gynandrous. Perianth adherent (superior), coloured, or rarely herbaceous; its parts arranged in 2 rows. Column consisting of the stamens and style consolidated into a central body. Stamens 3, the central only being perfect, except in Cypripedium, where the central is abortive and the two lateral perfect; pollen powdery, or cohering in waxy masses. Ovary adherent (inferior), 1-celled, composed of 6 carpels, of which 3 have parietal placenta; stigmas usually confluent in a mucous disk. Capsule membranous or coriaceous, rarely fleshy. Seeds innumerable, without albumen; embryo solid. Roots fasciated and fibrous, sometimes with fleshy tubercles. Leaves never lobed; their veins usually parallel, very rarely somewhat reticulated. Stem sometimes swollen and jointed, forming pseudo-bulbs.

**Properties.**—See Sulp and Vanilla.

---

2. It would appear, however, that the term tribal of Paradise is also applied, in Ceylon, to Alpinia Alivagas. (See Burman's Theeawus, p. 54; and Sir J. E. Smith, in Rees's Cyclopedia, vol. xxxix, art. Alpinia.)
4. Accounts of Ceylon, 1805.
93. Orchis, Linn.

Sex. Syst. Gynandria, Monandria.

(Radix; Salep.)

The term salep¹ (radix salep) is applied to the prepared tubercles of several orchideous plants.

1. Oriental Salep.—This is usually imported from the Levant, and is said to be the produce of Turkey, Natalia, and Persia. It consists of small ovoid tubercles, frequently strung on a cord. In 1825–6, salep of the value of 35,000 francs was imported into France from Persia.²

Salep is the produce, probably, of different species of Orchis. Frans² states that the salep of Greece is collected from O. Moro, and also from O. mascula, coriophora, and undulatifolia. Dr. Royle thinks that the salep of Cashmere is obtained from a species of Eulophia. Caventou³ states that the constituents of salep are gum (which does not become coloured by iodine), much bassorin, a little starch, common salt, and phosphate of lime. Others, however, have found an abundance of starch in salep⁴ and it is probable, therefore, that the quantity varies at different seasons, and is most abundant before the tubercle is exhausted by the nutrition of the stem.⁵

2. Indig.ous Salep.—That prepared from Orchis mascula is most valued; but the roots of some of the painted sorts, as Orchis latifolia, are found to answer almost equally well. Geoffroy⁶, Reitzius⁷ and Moult⁸ have each pointed out the method of preparing it. The latter directs the roots to be washed and the brown skin removed by a brush or by dipping the root in hot water and rubbing it with a coarse linen cloth. The roots are then put on a tin plate and placed in an oven heated to the usual degree for six or ten minutes, in which time they will have lost their milky whiteness and acquired a transparency like horn. They are then removed and allowed to dry and harden in the air.

The fresh roots of the orchis contain a peculiar odorous principle (which is almost entirely dissipated by drying), starch, mucilaginous matter, a small quantity of bitter extractive, ligneous matter, salts, and water.

Salep possesses the dietetical properties of the starchy and mucilaginous substances (see ante, vol. i. p. 117). Its medicinal properties are those of an emollient and demulcent. It was formerly in repute as an aphrodisiac and restorative, and as a preventive of miscarriage,¹⁰ but it has no claim to these powers. The notion of its aphrodisiac properties seems to have been founded on the doctrine of signatures.

Indigenous salep was recommended by Dr. Thomas Percival¹¹ as a wholesome article of food; and in a medicinal point of view as a restorative, emollient, and demulcent.

Mucilage of salep (mucilago radicis salep; decoctum salep) is prepared, according to the Hamburg Codex, with 3 grains of powdered salep and 3/4 of distilled water. Dissolve by boiling and constantly stirring, and strain.

94. Vanilla, Swartz.

Sex. Syst. Gynandria, Monandria.

(Fructus.)

History.—Vanilla (so-called from vainilla or baynilla, the diminutive of vaína or baya, a sheath or pod) is said¹² to have been brought to the Continent, as a perfume, about the year 1510. It could not, however, have obtained much attention; for Clusius,¹³ who received it from England in 1602, confesses that he had not seen it before; and he calls it lobus oblongus aromatics. Hernandez¹⁴ describes the vanilla plant under the name of tilizochil or aracu aromatics. The pods were afterwards denominated benzanelles quasi benzionelles, on account of their benzoin-like odor.¹⁵

Botany. Gen. Char.—Fruit a long pulpy pod, with round seeds not inclosed in a loose membrane. (Lindley.)

¹ The term saleop is sometimes applied to saasafra tea.

Species.—Although, until recently, most authors have ascribed the vanilla of commerce to the *V. aromatica* of Swartz; yet the assertion rested upon no certain or known fact, but chiefly upon the belief that *V. planifolia* bore no odoriferous fruit. 1 Morren, 2 however, by artificial impregnation, obtained fruit from the *V. planifolia*, which, in fragrance and other qualities, vied with the best vanilla of commerce; and it is probable, therefore, that this species yields part at least of the best or Mexican vanilla.

But Schiede 3 states that there are four forms of Vanilla in Mexico, which he calls respectively *V. sativa, V. sylvestris, V. pompona, and V. inodora,* 4 the first two of which he thinks have been confounded under the name of *V. planifolia*. He did not, however, see the flowers of any of these species; and, therefore, it is impossible to characterize them. He likewise mentions a *baynila de mono or monkey vanilla*, which he did not examine; and also a *baynila mexica* or hybrid vanilla, a fruit not intermediate between that of *V. sativa* and *V. sylvestris.*

But although the best vanilla comes from Mexico, there are other sorts which are the produce of other parts of tropical America, and which are certainly not the produce of *V. planifolia*; I shall, therefore, also notice such other species as probably contribute some of the vanilla of commerce.

1. *V. planifolia*, Andrews, Bot. Rep. t. 538.—Fruit very long, cylindrical, and very fragrant.—West Indies (Aiton), Mexico (†), and Guatemala (?).—Probably yields the best Mexican Vanilla.—Schiede's *V. sativa* and *V. sylvestris* are perhaps referable to this species:—

2. *V. sativa*, Schiede; *Baynila mansa* or cultivated vanilla of the Mexicans. Leaves oblong, succulent, the floral ones very small; fruits without furrows.—Grows wild; and is also cultivated in Papantla, Misaunla, Nautla, and Colima.—Yields the finest sort of Vanilla. This, probably, is the *La Corrient* or Current Vanilla of Desvaux. 6

3. *V. sylvestris*, Schiede; *Baynila cimarrona* or wild vanilla of the Mexicans. Leaves oblong-lanceolate, succulent, the floral ones very small; fruits with two furrows.—Grows in Papantla, Nautla, and Colima.—Its fruit is collected in Papantla, and mixed with that of the preceding sort.—According to the information furnished to Desvaux, this form is the same species as the preceding; but, growing wild in the woods, and deprived of the solar rays, it yields a smaller fruit.

4. *V. aromatica*, Swartz, in Act. Upsal. vi. 66.—Fruit cylindrical, very long.—South America: Brazil.—Said by Martius to yield the true vanilla (vera silique vanilla).

6. *V. sativa*, Schiede; *Baynila pompona* or large vanilla of the Mexicans.—Fruit with two furrows, rich in volatile oil, with an agreeable odour, yet will not dry, but always remains soft, and cannot be transmitted to anyone as an article of commerce. Humboldt 7 says that it has scarcely any sale on account of its colour. Desvaux observes that it is certainly the vanilla called by some authors *bova* (vanilla bouffe, tumid or swollen vanilla), and which is found in French commerce under the name of *vanillon*.

CURING.—The preparation or curing of vanilla varies probably in different places. At Misaunla the fruits are sun-dried, and afterwards sweated in blankets; or, when the weather is unfavourable, they are dried by artificial heat. 8 In some places they are dipped in boiling water, then suspended in the sun to dry, and afterwards oiled. 9 These different processes have for their object not merely the preservation of the fruits, but the development and preservation of their colour, which is supposed to be effected by a kind of fermentation; for in the fresh state, Aublet says, they have no aroma. The heat of the colour has been variously stated to be in the seeds, the pulp, and the fruit coats: probably all these parts possess it in different degrees.

---

1 Planier, who published a figure of *V. aromatica*, expressly states in his MS., published by Geoffroy (*Tract. de Nat. Méd.*, t. ii. p. 863, 1741), that his plant differs from the Mexican species in being odorous.

4 *V. inodora*, the *baynila de sueco* or hog vanilla of the Mexicans, is, Schiede states, a distinct species, but, being deficient in volatile oil, is not used. Desvaux says that in drying it gives out a disagreeable odour, and from this has obtained the name of hog's vanilla.

5 Ann. Sciences Nat. 3me Ser. Botanique, t. vi. p. 119, 1846.—Desvaux says there are two varieties of *La Corrient*; one of which is well filled with seeds and pulp, and has a fine skin—this is the most esteemed; the other, or *Cutyada* (leathery), has a thick skin, and, though inferior, is legitimate in commerce: it is the *La Corrient* or Leg of some parts of South America.

7 Desvaux, op. supra cit.

9 VOL. 11. — 17
DESCRIPTION.—The dried fragrant fruits of several species of vanilla constitute the vanilla or vanillao of the shops (fructus vel capsula vanillae; siliqua vaniglia vel baniaghe).

Four sorts are known in the English market; viz., the Mexican or Vera Cruz, the Honduras, the La Guayra, and the Brazilian or Bahia. A fifth sort I have received by private hand.

1. **Mexican or Vera Cruz Vanilla.**—Imported from Vera Cruz, tied in bundles of 50 pods, weighing, when of good quality, about 9½ or 10 oz. The heavier the bundle, the better the quality and the greater the value per lb. The bundles come packed in tin cases, each holding 60 bundles. I have met with two varieties—

a. **Finest Mexican Vanilla.**—This consists of pods which are 7 or 8 inches long, ½ of an inch wide, tapering at the extremities, and curved at the base. They are longitudinally wrinkled, soft, clammy, and dark brown. Their odour is very fragrant, resembling, but being more delicious than, that of balsam of Peru. By keeping them become coated with brilliant acicular crystals, and are then called crystallized vanilla.

b. **Second Mexican Vanilla.**—The pods of this sort are shorter (being about 5 inches long), narrower, drier, paler, and less odorous than the preceding, with only a few isolated or no crystals on them. In other respects this sort agrees with the preceding.

Desvaux states that in Mexico five legitimate sorts of vanilla are distinguished: viz., the primera (the grande fina of Humboldt), or the finest; chica-fina (the mancurna of Humboldt), or small fine; sacate, or middlings; rescate, or middling-middlings; and basura, or the sweepings.

The puerca and pompona are not considered to be legitimate sorts.

**Bourbon Vanilla,** according to Bouchardet,1 differs from Mexican vanilla only in being somewhat smaller, redder, less brown, drier, and lessunctuous.

2. **Honduras Vanilla.**—Imported from Honduras. Its value is from 2s. to 4s. per lb. The fruits are cylindrical, or slightly flattened, 3½ or four inches long, ½d. or ½ths of an inch in diameter, longitudinally wrinkled, brown, and dry. Their odour is vanilla-like, but feeble, and not of that fragrant kind which characterizes the best vanilla.

3. **La Guayra Vanilla.**—Imported from La Guayra, in Venezuela, in various packages (mostly tins in cases). It is an inferior sort, chiefly used by perfumers, and fetched from 2s. to 4s. per lb.

The fruits are large flattened, or somewhat plano-convex, or obscurely triangulated pods, from 5 to 7 inches long, ½ to ¾ of an inch wide, somewhat narrowed at the extremities, a little twisted or curled, longitudinally wrinkled, here and there presenting a somewhat blistered appearance, brown, with a peculiar (sweetish fruity) vanilla odour. On the flattened side, at each edge, is a more or less distinct welt-like suture.

In the Museum of the Pharmaceutical Society are two pods, probably of the same sort, received from Mr. Stutchbery, of Demerara. They are, however, 7½ inches long, more distinctly triangular, blackish externally, and appear as if oiled. They were sent along with a pod of what I believe to be *V. guianensis*, preserved wet.

La Guayra Vanilla is probably the produce of *V. guianensis* of Splitberger. It is perhaps the *larger vanilla* (vanilla grosse) of Aublet; and is said by Dr. T. W. C. Martius to be sometimes met with under the name of *vanillon*.

4. **Brazilian or Bahia Vanilla.**—This consists of pods of about 7½ inches long and ¾ of an inch wide. The samples which I have seen have been divided longitudinally, and strictly speaking, therefore, are half pods. This sort is blackish, and damp and sticky to the touch, somewhat as if it had been covered with treacle or some glutinous substance. By digestion in spirit it is deprived of its glutinous coating. It is sometimes brought over quite wet. By some persons it is said to have been preserved in sugar, and that to this substance it owes its dampness. Its odour is not equal to that of the best vanilla.

This sort of vanilla corresponds with the fruit neither of *V. aromatica* of Swartz, nor of *V. palmarum*, Lindley—the only two species of vanilla which, according to Martius, are found in the Brazils. Is it *V. pompona* of Schiede?

5. **Panama Vanilla.**—I have received a single pod only of this. It is flat, 3½ inches long, nearly ½ of an inch wide, dark brown, and fragrant.

**Goodness.**—The best vanilla is dark shining brown, plump, heavy, pliant, and soft, and has a fine fragrant smell. The crystallized variety is preferred.

Shrivelled, dull, dry, pale or yellowish brown, faintly smelling, or musty or mouldy pods are bad.

Sometimes dry shrivelled pods are freshened up with balsam of Peru, or are rolled in benzoic acid to give them a crystallized appearance.

**Composition.**—The crystallized vanilla was analyzed by Bucholz,2 who obtained the following results: Odorous brownish-yellow fixed oil, 10.8; soft resin, scarcely soluble in ether, 2.3; bitter extractive with some acetate of potash, 16.8; acridulous, bitterish, astringent extractive, 9.0; sweet extractive, 1.2; succharine matter with benzoic acid, 0.1; gum, 11.2; starchy matter,

---

1 *Jour. de Pharm.* 3e Sér. t. xvi. p. 274, 1849.
YAMS. DIOSCOREA. 259

2.8; woody fibre, 20.0; oxidized extractive dissolved by potash, 7.1; gum extracted by potash, 5.9; benzoic acid, 1.1; water and loss, 5.7. — The ashes of the insoluble fibre consisted of the carbonates of soda, potash, lime and magnesia, sulphate of lime, sulphates, chlorides, alumina, oxide of iron, and oxide of copper.

The nature of the odorous principle of vanilla has not been satisfactorily made out. It probably resembles that of the balsam of Peru, and belongs to the cinnameine series. By distillation with water, alcohol, or ether, vanilla yields no volatile oil; the liquid obtained by distillation with water being nearly inodorous. It is said that when the fruit is mature it yields from two to six drops of a liquid which has an exquisite odour, and bears the name of balsam of vanilla—none of which, however, reaches Europe, though it is stated to be used in Peru.

The soft needle like crystals which incrust the finest kind of vanilla are usually regarded as either benzoic or cinnamonic acid. They are slightly soluble in hot water, and the solution, according to my experiments, reddens litmus. Bley,* who examined them, denies that their solution reddens litmus, and considers them to be a peculiar solid volatile oil. They require to be farther examined.

Physiological Effects.—Vanilla is an aromatic stimulant. Its effects probably resemble those of balsam of Peru. It is considered to have an exhilarating effect on the mental functions, to prevent sleep, to increase the energy of the muscular system, and to act as an aphrodisiac. 3

Uses.—As a medicinal agent it is not employed in England. On the continent it has been used in hysteria, melancholia, impotency, asthenic fevers, rheumatism, &c.

Its principal use in this country is to flavour chocolate and various articles of confectionery (ices, creams, &c.), liqueurs, &c. It is also employed in perfumery.

Administration.—It is exhibited in the form of powder or tincture.

1. Pulvis Vanilia; Powder of Vanilla.—Vanilla is powdered by the intervention of sugar. The pods being cut in small pieces are pounded in an iron mortar with sugar, then sifted, the residue powdered with more sugar, and so on. The powders are then to be mixed. The quantity of sugar required varies according to the state of dryness or succulence of the pods; but in general four parts of sugar are required for one part of vanilla. This powder is used for aromatizing various culinary and medicinal preparations. It may be administered medically in doses of a drachm; equal to about twelve grains of the pure vanilla.

2. Tinctura Vanilla; Tincture of Vanilla; Essence of Vanilla.—This is prepared by digesting one part of good Mexican vanilla in six parts of rectified spirit. When inferior sorts of vanilla are used, the proportion of this substance is increased.—Vogler* states that a tincture of balsam of Peru is sometimes substituted for that of vanilla.

2. Leaves with netted (reticulated) veins. Dictyogena; Retorea. Lindley.

† Flowers unisexual, with the perianth adherent to the ovary (inferior ovary).

ORDER XIX. DIOSCOREACEÆ, Lindl.—YAMS. DIOSCOREÆ, R. Brown.

Character.—Twining endogenous plants with reticulated leaves, unisexual regular flowers, a 6-parted superior perianth, 6 stamens, a 3-celled inferior ovary with 1- or 2-seeded cells, and capsular or burred fruit.

Properties.—See Dioscorea and Tamus.

95. Dioscorea, Linn.—The Yam.

Sex. Syst. Diosc. hexandria. (Tuber.)

In tropical countries (East and West Indies, Africa, Polynesian) the tuberous roots of many species of Dioscorea or Yam* are used as food. Of seventeen species described by Roxburgh,* eleven are stated to be employed for food. The four following are cultivated in India, and are esteemed in the order in which they are enumerated: D. globosa, D. alata, D. purpurea, and D. rubella. Roxburgh also says that D. atropurpurea is extensively cultivated at Malacca, Pegu,

* An odour more or less allied to that of vanilla, and therefore called the vanilla odour, is common to many vegetable substances (see Virrey, Journ. de Pharm. t. vi. p. 391; also, Mérat and De Less, Dict. Mén. Méd. t. vi. p. 819, and Suppl. p. 797.)
* Pharmacoeuticale Central Blatt für 1831, p. 579.
* Pharmacoeuticale Central Blatt für 1848, S. 448.

and the eastern islands; and that *D. fasciculata* is cultivated to a considerable extent in the vicinity of Calcutta, not only for food, but to make starch of the roots. In the West Indies several species are used as food; the chief are *D. aculeata*, *D. alata*, *D. bulbifera*, and *D. sativa*. The tuberous roots sold in the London shops as West India yams are said to be those of *D. alata*.

Yams are large fleshy roots, sometimes weighing from thirty to forty pounds each. Some of them are highly acid in the fresh state, but become agreeable articles of food when cooked, owing to the dissipation or decomposition of the acid principle.

The fresh root of *Dioscorea sativa*, from the West Indies, was analyzed by Siersen, who obtained the following results: resin, 0.05; uncrystallizable sugar, 0.25; mucilage, 2.84; starch, 22.66; ligneous fibre, 6.51; nitrogenized matter, quantity undetermined; and water, 67.58. The fresh roots yield 0.52 of ashes, containing carbonate of lime and silica.

The following are the per centage quantities of yam-starch obtained by Dr. Sheir from the fresh roots of several species of *Dioscorea*:

I am indebted to Dr. Sheir for specimens of the starches of three species: viz., *D. sativa*, *D. aculeata*, and *D. triphylla*. They were prepared in the Colonial Laboratory at Demerara. They are beautifully white, inodorous, and tasteless. Examined by the microscope, the particles of the three starches present a general similarity of character. They are large, somewhat compressed, elliptical or ovate, or somewhat obliquely triangular. They may be compared in shape to the seed of the common scarlet runner bean (*Phaseolus multiflorus*), and are surrounded by rings, which, when viewed on the middle of the flat side of the particle, appear to be but slightly curved. In the latter character they approximate to curcula starch. Some of the particles present one or two slight nipple-like projections analogous to those of manara starch. In polarized light, they present the usual crosses observed with most other starches. Their size is about 7/16th of an inch in length, and about 3/32th of an inch in breadth.

Yams are roasted and boiled, and eaten like potatoes. "They are dressed in various forms, being boiled in soups or broths, &c., made into pudding, or roasted in the fire." Some of them, however, are violently acid, causing vomiting and diarrhoea, even after being carefully cooked. This is said to be the case with *D. triphylla* and *demonan*. Yet Dr. Wright and Dr. Sheir declare that the roots of *D. triphylla* are nearly equal to potatoes.

96. *Tamus communis*, Linn.—Common Black Bryony.

The root (radix bryonia nigra) is large and fleshy, black externally, white internally. When fresh, it possesses some acidity. No analysis of it has been made. Taken internally, it acts as a diuretic, and has been esteemed as a nutritive agent (see vol. i. p. 283). It is kept in the herb shops, and sold, like Solomon's seal (see *ante*, p. 215), as a topical application for removing bruise marks. In France, it is called the *herbe aux femmes baïlous*, or the herb for bruised women.

-flowers with the perianth free from the ovary (superior ovary).

ORDER XX. SMILACEÆ, Lindl.—SARSAPARILLAS.

Character.—Flowers biennial or polygamous. Calyx and corolla both alike, free, 6-parted. Stamens 6; inserted into the perianth near the base; seldom hypogynous. Ovary 3-celled, the cells 1- or many-seeded; style usually trifid; stigmas 3. Fruit a roundish berry. Albumen between fleshy and cartilaginous; embryo usually distant from the hilum.—Herbaceous plants or under shrubs, with a tendency to climb. Stems scarcely woody. Leaves reticulated. (Lindley.)

Properties. See Smilax.—The Rheugonum parviforum of R. Brown, a native of New Zealand, where it is called karea, is said to possess virtues similar to those of sarsaparilla, and may be termed the New Zealand sarsaparilla. The stems yield 12 per cent. of extract, which is bitter, and contains starch-gum and traces of astringent matter.

97. SMILAX, Linn., several Species of, yielding Sarsaparilla.

Sex, Syst. Diocia, Hexandria.

History.—The root of sarsaparilla was brought into Europe from the West Indies, about the year 1530, with the character of being a medicine singularly efficacious in the cure of lues venerea.° Monardes says that, when the Spaniards first saw it, they called it garça-parilla, on account of its resemblance to the carça-parilla of Europe (Smilax aspera). The Spanish term zarzapasilla (from zarza, a bramble; and parilla, a vine) signifies a thorny vine.

Species.—Considerable uncertainty prevails as to the botanical origin of the various sorts of sarsaparilla of commerce. From four species of Smilax, a great part, at least, of this drug is obtained.

1. S. officinalis, HBK.—Stem twining, shrubby, prickly, quadrangular, smooth; the young shoots are unarmed, and almost round. Leaves ovate-oblong, acute, cordate, netted, 5- to 7-nerved, coriaceous, smooth, a foot long, and 4-5 inches broad; the young ones are narrow, oblong, acuminate, and 3-nerved. Petioles smooth, an inch long, bearing 2 tendrils above the base. Flowers and fruit unknown. —Grows in New Granada, on the banks of the Magdalena, near Bajourque. It is called zarzaparilla by the natives, who transmit large quantities of it to Cartagena and Mompox; whence it is shipped for Jamaica and Spain (Humboldt). 5 According to Pohl, it is collected near the river Abaité, in the western part of the province of Minas Geraes (Martius).

This species probably yields the sarsaparilla exported from Colombia (Savanilla, Santa Marta, Caracas, and its port La Guayra, St. Margarita and its port Porta Arenas), and Guatemala (Costa Rica).

2. S. medica, Schlechtendal, in Linneæ, vi. 47.—Stem angular, armed at the joints with straight prickles, with a few hooked ones in the intervals. Leaves shortly acuminate, smooth, 5- to 7-nerved; inferior ones cordate, auriculate-hastate; upper ones cordate-ovate. Peduncle axillary, smooth, about an inch long. Inflorescence

° CIusii Exotic. lib. x. cap. xxii. p. 317.
an 8- to 12-flowered umbel. Fruit red, size of a small cherry; contains 1—3 reddish-brown seeds. Embryo cylindrical, lodged in horny albumen (T. F. L. Nees).¹

Schiede² says, that of the numerous species of Smilax which grow on the eastern slope of the Mexican Andes, this is the only species which is collected in the villages of Papantha, Tuspan, Nautla, Misantla, &c., and carried to Vera Cruz, from whence it is sent into European commerce under the name of sarsaparilla. We may, therefore, safely state that Mexican sarsaparilla (Vera Cruz and Tampico) is the produce of this species.

3. S. Papyracea, Poiret; S. sphyilitica, Mart. (non Humb.) Reise, iii, 1280; Sipó ém of the natives.—Stem 4-cornered or plane-angular, polished, prickly. Leaves somewhat membranous, oval-oblong, obtuse at both ends, or usually pointelleted at the apex, quite entire, unarmred, 5-ribbed, with 3 more prominent ribs. Currh inserted beneath the middle of the petiole.—Province of Rio Negro, in marshy spots on the Japura, near Porto dos Miranhas (Martius); near Ega (Poepigg); and near Borba, in the province of Rio Negro (Riedel).—Yields Brazilian (also called Maranh, Para, or Lisbon) sarsaparilla.

The "Rio Negro Sarsa"³ of Dr. Hanceck is perhaps the produce of this species.

The preceding are the species of Smilax, from which probably the greater part, if not all, of the sarsaparilla of commerce is obtained. Other species, however, which have been mentioned in connection with this drug, require to be noticed.

4. S. sarsaparila, Linn.—It is common in the hedges and swamps of the United States of America; but, notwithstanding its name, it does not yield any of the sarsaparilla of commerce: and there is no evidence that it ever did yield any. Dr. Wood⁴ remarks that its root would certainly have been dug up and brought into the market, had it been found to possess the same properties with the imported medicine.

5. S. Sphyilitica, HBK.—Humboldt and Bonpland discovered it in New Granada, on the river Cassiquiare, between Mandavala and San Francisco Solano.⁵ In the former edition of this work, I stated, on the authority of Martius,⁶ that this species yielded Brazilian sarsaparilla. But this botanist has subsequently⁷ ascertained that he had mistaken & papyracea for this species.

Poepigg⁸ states that S. sphyilitica, HBK., is collected at Maynas (in Colombia), and forms the sara fana which is mixed with sara gruda (S. cordato-ovata, Pers.), and sent to Para.

6. S. Cordato-Ovata, Persoon.—Cayenne; Maynas. Yields sara gruda (see supra).

7. S. Purhampt, Ruiz, Memoria sobre las virtudes, &c., &c., Purhampt, p. 65.—Peru. Yields one of the best sorts of sarsaparilla, which Ruiz calls China peruviana. Lindley⁹ thinks this may be the same species as S. officinalis.

8. S. Obliquata, Poiret.—Peru. Guibourt¹⁰ ascribes to this species the Peruvian sarsaparilla of commerce, but I know not on what authority.

General Description.—The sarsaparilla or sarza (more properly zarza) of commerce (radix sarsaparilla vel sarza) consists essentially of the roots of the before-mentioned, and perhaps also of other species of Smilax. In some sorts of sarsaparilla the roots are attached to a portion of the rhizome.

a. The rhizome or rootstock (rhizoma), called by druggists the chump, is a tuberous subterranean stem, which in the living plant is placed horizontally or obliquely in the earth. It grows throwing out aerial stems and roots at the more pointed extremity, and gradually dies off at the thicker and older end. One or more aerial stems are frequently found attached to the rhizome of the shops: these are rounded or square, with nodes and usually with aculei or prickles. If a transverse section be made of either the rhizome or aerial stem, no distinction of bark, wood, and pith is perceptible.

b. The roots (radices) are called by Schleiden¹¹ adventitious (r. adventitiae): they are usually several feet long, and of variable thickness; on the average about that

⁷ Flera Medica.
⁹ Jahresbericht über die Fortschritte in der Pharmacie im Jahre, 1817, p. 81.
of a writing quill. The thin shrivelled roots are more or less wrinkled or furrowed longitudinally, and in trade are usually said to be lean; while the thick, plump, swollen ones are described as being gouty. The latter usually abound in starch, and are said to be mealy. Frequently, especially in some sorts of sarsaparilla, the roots are said to be bearded; that is, they give off, more or less abundantly, fibres, which are themselves often divided into fibrils.

The colour of the roots varies, being more or less red or brown, frequently with a grayish tint. The washed or unwashed condition, the greater or less care taken of them in drying, the time of year when they were collected, the colour and nature of the soil in which they grew, as well as the species or sort of plant from which they are obtained, and many other circumstances, doubtless modify the colour. The taste of the root is mucilaginous, and slightly acrid. The acridity is only perceived after chewing the root for a few minutes. The odour is somewhat earthy.

By a transverse section the roots are seen to consist of a cortex or rind, and a ligneous cord or meditullium inclosing the pith, somewhat in the manner of an exogenous stem.

The cortex or rind consists 1st, of the cuticle or epidermis, composed of compact cells; 2dly, of the outer cortical layers, composed of coloured (from golden yellow to deep orange-red), elongated, thick, flattened cells (some of which are porous), which form a subcuticular tissue (epiphleum or periderm?); and, 3dly, of the inner cortical layers, consisting of shorter, thinner, cylindrical, often porous cells with large intercellular spaces. In some sorts of sarsaparilla most of these cells abound in starch, while a few contain bundles of acicular crystals (oxalate of lime?) called raphides. The mealy cortex is frequently colourless, but sometimes has a roseate tint.

The ligneous cord or meditullium consists of 1st, a cellular layer (liber?), called by Schleiden the Kernsheide or nucleus-sheath, whose cells are empty, thick, and strongly coloured (like those of the outer cortical layers); 2dly, a woody zone, called by Schleiden the Gefässbündelkreis or vascular-bundle-circle, usually of a pale yellowish colour, and composed of woody tissue, vessels,1 and cambial cells; and, 3dly, medulla or pith, generally colourless, composed of cylindrical cells (like those of the inner cortical layers) which often abound in starch. Sometimes an isolated vessel, or a small group of vessels surrounded by a thin layer of ligneous cells, is seen in the pith.

Fig. 266. Fig. 267.

Fig. 266. Transverse section of the cortex and half of the diameter of the meditullium. Fig. 267. Longitudinal section of the cortex.

Magnified Sections of Sarsaparilla.

a. Cuticle or epidermis. b. Outer cortical layers (subcuticular tissue). c. Inner cortical layers. Most of the cells abound in starch; some few contain raphides (see Fig. 267). d. Cellular layer or nucleus-sheath. e. Woody zone (vascular-bundle-circle). f. Medulla or pith.

1 The apertures in the woody zone, seen with the naked eye in a transverse section of the root, are those of large vessels. Occasionally we perceive an isolated bundle of vessels whose interior is filled up with a yellowish-red colouring matter.
The chief anatomical characters, which vary in the different species of sarsaparilla, are the relative breadths of the cortical, ligneous, and medullary layers, the characters of the cells of the nucleus sheath, and the number of layers composing the subcuticular tissue. Schleiden pretends that he can, by these characters, distinguish the South American, Central American, and Mexican sarsaparillas from each other. The following is the way in which he applies them: South American sarsaparillas, he says, have, almost without an exception, a mealy cortex and a vascular-bundle-circle whose breadth, from the nucleus sheath to the pith, is one-fourth, or at most one-third, the diameter of the pith. They have, therefore, a large white pith. The Central American and Mexican sarsaparillas have, on the other hand, a vascular-bundle-circle whose breadth is commonly equal to, and sometimes exceeds, the diameter of the pith. Sometimes, but rarely, the pith is half as thick again as the vascular-bundle-circle. The Central American and Mexican sarsaparillas are, according to Schleiden, readily distinguished from each other by the nucleus sheath, whose cells, in the Central American sorts, are either quadrangular or somewhat elongated transversely (tangentially), and are nearly equally thick on all sides (Fig. 268); whereas in the Mexican sort these cells are elongated in the direction from within outwards (radially), and have walls which are thicker on the inner than on the outer side (Fig. 269).

![Magnified Views of the Cells composing the Nucleus Sheath (according to Schleiden)](image)

The Central American and Mexican sorts are less strikingly distinguished, according to Schleiden, by the external cortex (subcuticular tissue), which, in the Central American, consists of only one, rarely two, layers of very thick cells, and altogether has fewer cellular layers; while the Mexican has from 2 to 4 layers of very thick cells, and altogether sometimes 6 or 7 layers.

Commercial Sorts.—Several sorts of sarsaparilla are met with in commerce, and are well known to our dealers; but I find that, with some exceptions, there is a great want of precision in the names applied to some of the varieties. The terms Jamaica, Lima, Honduras, and Lisbon or Brazilian, are, by English dealers, applied to sorts which are well known to them either by the characters of the roots or the mode of packing. There is another kind, called by English druggists gouty or Vera Cruz sarsaparilla, which appears to me to be identical with that called by Continental and American writers Caraccas sarsaparilla, under which name I shall describe it.

a. Geographical Classification.—Sarsaparilla is exclusively the produce of America, and grows in the southern part of North America and the northern part of South America. The exact limits are not known.

1. Mexican sarsaparilla.—This is the produce of Smilax medica, and is the growth of Papantla, Tuspan, Nautal, Misantla, &c. It is usually shipped at Vera Cruz, and is, therefore, usually known in commerce by the name of Vera Cruz sarsaparilla. From Tampico, another Mexican port, a similar sort of sarsaparilla is also exported, which is known in Europe as Tampico sarsaparilla. According to Monardes, the first sarsaparilla which came to Europe was brought from New
Spain (Mexico). He describes it as being whiter, somewhat yellowish, and smaller than the Honduras sort.

2. Central American sarsaparilla.—Guatemala produces sarsaparilla, which is sometimes exported to Jamaica; but it is not distinguished in European commerce as the produce of Guatemala. Honduras sarsaparilla is a well-known and distinct sort in the London market. Monardes says it was the second kind known in Europe. He describes it as darker and thicker than the Mexican sort; and says that it was more esteemed. Costa Rica sarsaparilla is usually sold as Lima sarsaparilla, with which it agrees in quality. Much sarsaparilla is collected on the Mosquito coast by the Seeo Indians, who sell it to the Sambos. The latter carry it in their doreys to Truxillo, where they barter it for goods. I have been informed that sarsaparilla, the produce of the Mosquito Shore of St. Juan de Nicaragua, is sometimes sent to England by way of Jamaica.

3. Colombian sarsaparilla.—Since 1831, Colombia has been divided into three independent states, viz., New Granada, Venezuela, and Ecuador, from all of which sarsaparilla is exported to Europe, either directly or indirectly, by way of Jamaica or New York.

4. New Granada.—According to Humboldt and Bonpland, sarsaparilla (Smilax officinalis) is collected on the banks of the Magdalena, and transmitted to Cartagena and Mompox, whence it is shipped for Jamaica and Spain. Occasionally sarsaparilla is imported into England from Santa Marta and Savanilla.

5. Venezuela.—From La Guayra (the sea port of the Caraccas) is shipped to the United States of America and Europe Caraccas sarsaparilla. Sarsaparilla is sometimes imported into England from Porta Arenas.

6. Ecuador.—Occasionally sarsaparilla is imported into London from Guayaquil; but whether it is the produce of Maynas or of Central America I know not.

4. Brazilian sarsaparilla.—This is a well-known sort, and is imported from Para; and according to Martius is the produce of Smilax papyracea. Poepig, however, says that two sorts of sarsaparilla, sarsa fina and sarsa gruosa, are collected in Maynas and transmitted to Peru: the first is the produce of Smilax syphilitica, the second of S. cordato-ovata.

5. Peruvian sarsaparilla.—Sarsaparilla is sometimes imported from Lima; but whether it is the produce of Peru or of Maynas, or of Central America, I know not. Under the name of Lima sarsaparilla is sold, not only the sarsaparilla from Lima, but also that from Costa Rica. It is probable that no sarsaparilla grows on the western declivity of the Andes, and that the sarsaparilla exported from Lima is either the produce of Maynas or has been carried to Lima from some other ports on the Pacific.

A considerable quantity of sarsaparilla is imported into London from Jamaica (Jamaica sarsaparilla), from Valparaíso, and from New York; and formerly also from Lisbon (Brazilian sarsaparilla). But it is not the produce of these places.

B. Qualitative Classification.—The various commercial sorts of sarsaparilla differ from each other in the anatomical and other characters of the roots, in the manner in which they are folded and packed, and in the absence or presence and character of the attached rhizomes and stalks.

I have already given a sketch of Schleiden's anatomical arrangement of the commercial sorts of sarsaparilla roots. I shall not adopt it, because I do not consider it accurate or easily applied. His classification would associate Costa Rica sarsaparilla with that of Honduras, and the Lima with the Caraccas and Brazilian sorts.

I shall arrange the sarsaparillas of commerce in two divisions: the first including those commonly termed mealy; the second, those which are not mealy.

1 Young, Narrative of a Residence on the Mosquito Shore during the Years 1839, 1840, and 1841, Lond. 1842.
Div. 1. Mealy Sarsaparillas.
(Sarsaparillæ farinose seu amyloaceæ.)

These are characterized by the mealy character of the inner cortical layers, which are white or pale-colored. The meal or starch is sometimes so abundant, that a shower of it, in the form of white dust, falls when we fracture the roots. The thickest mealy coat which I have measured was barely \( \frac{1}{10} \) th of an inch in thickness. Compared with the diameter of the meditullium or ligneous cord, the thickness of the mealy coat is sometimes nearly equal to it, but usually does not exceed \( \frac{2}{3} \) or \( \frac{1}{3} \) of it. The thick mealy roots have a swollen appearance, and are technically called *gouty* by the dealers: the cortex, being brittle, is frequently cracked transversely in rings, and readily falls off. The colour of the mealy coat varies from white to yellowish or pinkish.

The medulla or pith is frequently very amyloaceus.

If a drop of oil of vitriol be applied to a transverse section of the root of mealy sarsaparilla, the mealy coat is *but little altered in colour*; while the woody zone becomes dark purplish or almost black. Sometimes the pith also acquires a darkish tint.

A decoction of mealy sarsaparilla, when cold, becomes dark blue on the addition of tincture of iodine.

The aqueous extract of mealy sarsaparilla, when rubbed down with distilled water in a mortar, does not completely dissolve, but yields a turbid liquid, which becomes blue on the addition of iodine.

This division includes three commercial sorts of sarsaparilla; namely, the Brazilian, the Honduras, and a third kind, which by English dealers is commonly called *gouty* or Vera Cruz sort, but which, by Continental and American writers, is usually denominated Caraccas.

They may be subdivided thus:

A. Pith 2 to 4 times the breadth of the woody layer; cells of the nucleus sheath elongated radially.
   a. Pale, folded, often swollen (or gouty) roots with the rhizomes or stems attached
   b. Reddish-brown, unfolded roots with rhizomes or stems attached, packed in rolls or cylindrical bundles
   
1. Caraccas.

B. Pith 1 to 1½ times the breadth of the woody layer; cells of the nucleus sheath square or elongated tangentially

2. Brazilian.

3. Honduras.

1. Caraccas Sarsaparilla (Radix Sarsaparillæ de Caraccas)._This is the *gouty* or Vera Cruz sarsaparilla of most English dealers. It would appear to come to this country by various routes. One sample, which I have received, came, as I was informed by Mr. Price (of the firm of Price and Gifford, drug brokers), from the Pacific side of South America by way of Valparaiso. Mr. Luckombe, of the firm of Hodgkinson and Co., informs me that some of this sort of sarsaparilla has come by way of New Orleans. Dr. Wood\(^1\) states that it is imported in large quantities into the United States from La Guayra (the port of the Caraccas). He says it comes in oblong packages of about one hundred pounds, surrounded with broad strips of hide, which are connected laterally with thongs of the same material, and leaves much of the root exposed. The roots, he adds, are separately, closely, and carefully packed, and are often very amyloaceus internally.

---

\(^1\) United States Dispensatory.
Sarsaparilla:—Brazilian Sorts.

I have a bundle (Fig. 271) of this sarsaparilla (called by English druggists *gouty* or *Vera Cruz sarsaparilla*) which was imported into Liverpool from Valparaiso. It weighs 5½ lbs. It is flattened, about 2¼ feet long, scarcely 1 foot broad at its widest parts, and is 3 or 4 inches thick. At each extremity are two rhizomes, with portions of rounded or obscurely square stems bearing a few small prickles. The roots are pale yellowish or reddish-gray, and are very amylaceous. The cells of the nucleus sheath are elongated radially, and their walls are thicker on the inner side (Fig. 269).

This sort is probably the produce of *Smilax officinalis* and *S. syphilitica*, HBK. Guibourt's *Maracaibo sarsaparilla* is perhaps only a variety of *Caraccas sarsaparilla*.

2. Brazilian Sarsaparilla; Lisbon, Portugal, or Rio Negro Sarsaparilla (Radix *Sarsaparillae braziliensis*, seu *lisbonensis*; *S. de Maranon*; *S. de Para*; *S. insipida*).—Prior to the introduction of the Jamaica sort of sarsaparilla into the London market, the Lisbon sort commanded the highest price.¹ This is usually imported from Para and Maranham. It is brought over unfolded, tied in rolls or cylindrical bundles (*sarsaparilla longa*) of from three to five feet long, and about a foot in diameter.

In the museum of the Pharmaceutical Society is a roll (Fig. 272) weighing 14½ lbs.; its length is 3 feet 1 inch, and its diameter 7 inches.

Martius\(^1\) says that the Indians gather it all the year round, according to the state of the weather and of the rivers. After being dried over a fire, the roots are tied up in bundles with a flexible stem called *Timbotitica*; and to prevent them being worm-eaten, they are preserved in the gables of the houses, where they are exposed to smoke.

The same writer\(^2\) also states that this sarsaparilla is the produce of *Smilax papyracea* and *S. officinalis*. Poeppig tells us that there are two sorts of sarsaparilla which the dealers mix together; these are *sarsa fibra*, a thin, lean sort, less active, but also less liable to be worm-eaten—and *sarsa grulla*, a thicker, more active sort, but more liable to be attacked by insects: the first, he says, is the produce of *S. syphilitica*, the second of *S. cordato-ovata*. Schleiden suggests that *S. Purhampy* of Ruiz may perhaps yield some Brazilian sarsaparilla.

3. *Honduras Sarsaparilla*; *Mealy Sarsaparilla* (*Radix Sarsaparilla de Honduras*; *S. acris vel guturalis*).—It is imported from Belize, and other parts of the Bay of Honduras. It comes in large and smaller bundles, two or three feet long, folded lengthwise (in a kind of hank), and secured in a compact form by a few transverse circular turns. A large bundle (Fig. 273) in the museum of the Pharmaceutical Society is 2\(\frac{3}{4}\) feet long, from 10 to 12 inches in diameter, and weighs about 17 lbs. A smaller bundle (Fig. 274) is 2 feet 2 inches long, 3\(\frac{1}{4}\) inches in diameter, and weighs about 2 lbs.

The bundles are packed in bales, weighing from 80 to 110 lbs. or more, and imperfectly covered by skins. In the interior of the bundles are found roots of inferior quality, rhizomes with adherent stems, stones, clumps of wood, &c. The roots are furnished with a few rootlets. The general colour of the roots is dirty grayish or reddish brown. The cortex is very mealy, and the meditullium or central cord is thinner than in the Jamaica sort. The cells of the nucleus sheath are square, or are elongated tangentially, and are equally thick on all four sides (see Fig. 268).

The taste of the root is amylaceous, and ultimately somewhat acid. Its decoction becomes intensely blue by the addition of a solution of iodine. Its powder is fawn-coloured, and, when rubbed with water and tincture of iodine, becomes intensely bluish black. From five pounds of the root of fine quality about one pound of extract may be produced (Hennell). A sample, examined by Mr. Battley, yielded six and a half ounces of extract from three pounds of root, which is

\(^1\) *Reise*, Bd. iii. S. 1260.  
\(^2\) *Systema Nat. Med. Brasil.*
Sarsaparilla:—Non-mealy Sorts; Jamaica Sort.

about ten and a half ounces from five pounds: 874 grains of the cortical portions of the root yielded 230 grains of extract (Battley). In one operation, in the laboratory of a friend of mine, 170 lbs. of root yielded 45 lbs. of extract. According to Mr. Pope, the cortex yields twice as much extract as the medullium.

Nothing whatever is known respecting the botanical origin of this sort of sarsaparilla.

Div. 2. Non-mealy Sarsaparilla.
(Sarsaparilla non-farinose vel non-amylaceae.)

The sarsaparillas of this division are characterized by a deeply coloured (red or brown) usually non-mealy cortex. The cortex is red and much thinner than in the mealy sorts. Although by the microscope starch grains can be detected in the inner cortical layers, yet their number is comparatively small, and is quite insufficient to give the mealliness which characterizes the sarsaparilla of the first division. The diameter of the medullium or ligneous cord is much greater than in the mealy sarsaparillas, and is frequently six or more times greater than the thickness of the cortex. The roots have never that swollen appearance called by dealers gouty, and which is frequently observed in the mealy sorts.

Starch grains are usually recognizable in the pith by the microscope.

If a drop of oil of vitriol be applied to a transverse section of the root of the non-mealy sarsaparillas, both cortex and wood acquire a dark red or purplish tint.

A decoction of non-mealy sarsaparilla, when cold, does not yield a blue colour when a solution of iodine is added to it.

This division includes the sorts known in commerce by the names of Jamaica and Lima sarsaparillas, as well as a sort which I have received as a lean Vera Cruz sarsaparilla.

They differ from the Caracas, Brazilian, and Honduras sarsaparillas, in having a red or brown usually non-mealy cortex. In the relative thickness of the pith and woody layer they agree with the Honduras sarsaparilla; but they differ from it in having the cells somewhat elongated radially, in this respect approaching the Caracas and Brazilian sorts.

I have been unable to detect any anatomical difference between the roots of the Jamaica, the so-called Lima, and the lean Vera Cruz sorts. The Jamaica and Lima sorts are, I believe, not essentially different from each other. Both are probably the produce of Central America. They differ in colour somewhat, in the mode of packing, and in the route by which they reach England. What I have received as lean Vera Cruz sarsaparilla, might pass for a lean, thin, pale-coloured Lima sort whose roots are unfolded.

4. JAMAICA SARSAPARILLA, offic.; Red-bearded Sarsaparilla (Radix Sarsa-
parillae jamaicensis vel rubrae).—This sort first appeared in the London market about 1819 or 1820. The roots are folded and made up in bundles (sarsaparilla rotunda) of about a foot or half a yard long, and four or five or more inches broad. These bundles are neither trimmed nor closely packed.

The bundle from which Fig. 276 was taken, was about 17 inches long.

from 5 to 7 inches wide, and 3 inches thick; its weight was 21½ oz. In the museum of the Pharmaceutical Society are some plaits of Jamaica sarsaparilla. One of these (Fig. 277) weighs 5½ ounces, and is 4½ feet long, and 1½ inches wide.

Fig. 277.

A Plait of Jamaica Sarsaparilla.

The bundles of Jamaica sarsaparilla are packed in circular bales of from 60 to 80 lbs. each. The roots of this sort are long, slender, furnished with numerous small fibrous rootlets (called the beard). Its cortex is brownish, but with an orange-red tint, which distinguishes it from other kinds of red sarsaparilla. The cortex is reddish, and when examined by the microscope is found to contain some starch globules. The meditullium has frequently a reddish tint. When chewed, Jamaica sarsaparilla tinges the saliva. Its taste is not remarkably mucilaginous, but slightly bitter, and after a few minutes slightly acrimonious. Its decoction is deepened in colour by a solution of iodine, but no blue is perceptible. Its powder is pale reddish-brown, and when rubbed with water and tincture of iodine becomes blue, but less intensely so than the powder of the Honduras variety. It yields a larger quantity of extract than the other varieties; its extract is perfectly soluble in cold water. From three pounds of average quality about one pound of extract may be obtained (Hennell, also Battley); but from the same quantity of root of very fine quality, nearly one pound and a quarter of extract may be procured (Hennell). 874 grains of the cortical portion of the root yielded 484 grains of extract (Battley). According to Mr. Pope, the cortex yields five times as much as the meditullium.

The following are the characters of Jamaica sarsaparilla according to the London Pharmacopoeia (1851):

Reddish, copiously covered with rootlets, with a non-mealy bark.

Jamaica sarsaparilla is not the produce of the island whose name it bears, but, as I have been informed by wholesale dealers, of the Mosquito shore on the eastern coast of Honduras and of St. Juan, from whence it is brought to England by way of Jamaica; and occasionally it is said to be brought from Guatemala.

I am indebted to Mr. G. R. Porter, of the Board of Trade, for the following official account of the sources of Jamaica sarsaparilla:

Account of the Quantities of Sarsaparilla Imported into Jamaica in each year from 1840 to 1845, distinguishing the Countries from which Imported.

This accords with Humboldt's statement before mentioned (see ante, p. 265) that sarsaparilla is exported from Colombia (he says from Carthagena and Mompox) into Jamaica.
But, although this table may be relied on for showing the countries from which sarsaparilla is imported into Jamaica, it does not establish the place of growth.

It is probable that Jamaica sarsaparilla is the produce of *Smilax officinalis*.

In the collection of Materia Medica at Apothecaries’ Hall, London, is a sample of sarsaparilla said to have been grown in Jamaica; but it does not resemble the Jamaica sarsaparilla of commerce. Its colour is pale cinnamon brown. Internally it is mealy.

5. **LIMA SARSAPARILLA** (*Radix Sarsaparillae de Lima*).—This name is, of course, strictly applicable to sarsaparilla brought from Lima only, from whence, in fact, the first parcels came. But of late years sarsaparilla of the same quality has been brought from various other places; and the dealers, to distinguish it from other kinds, have called it the Lima sort; and gradually the term Lima sarsaparilla has been applied, rather to indicate the quality than the place of shipment. The true Lima sort is brought round Cape Horn; whereas much of the so-called Lima sort is the produce of Costa Rica, and is brought from the Caribbean Sea. I know of one importation of 99,000 lbs. from Costa Rica. The Lima sort is also brought from Guayaquil and Valparaiso.

Although some druggists prefer good parcels of Costa Rica to Lima sarsaparilla, still the general run of the Lima parcels comes nearer to Jamaica than the Costa Rica sort. On the whole, however, it is difficult to say whether any dealer can with certainty distinguish the Lima and Costa Rica sorts.

I am informed that the Costa Rica sort sometimes comes from St. Marta, Savanilla, and Caracas; though that from Costa Rica is usually of a better description.

Lima (including Costa Rica) sarsaparilla is imported folded in bundles or hanks of about 2 or 3 feet long, and 6 or 9 inches in diameter, with the attached rhizome (chump) contained in the interior of the bundle. The bundle, of which a cut (Fig. 278) is subjoined, came via Jamaica: it weighed 2 lbs. 13 oz.; was 2 feet long, and 6 inches in diameter.

![Image](Bundle of Lima Sarsaparilla)

The bundles are usually packed in bales of from 60 to 80 lbs. each.

In quality, Lima sarsaparilla closely resembles the Jamaica sort; but it yields a smaller quantity of extract. Its colour is brown or grayish-brown. Occasionally a few roots are found in a bale of good Lima sarsaparilla, which, as well as their rhizome and stem, are light clay-coloured. The stems are square and prickly: the prickles are few and small, except in the clay-coloured variety.

Lima sarsaparilla is probably the produce of *Smilax officinalis*.

Occasionally a knobby root or rhizome, like the *radix Chinea*, with a round stem, and long, smooth, wiry, brown root-fibres, is found in a bale of Lima sarsaparilla. A transverse section of the stem presents, to the naked eye, a structure somewhat similar to that of the common cane. I have received the same root (under the name of *Sarsaparilla-Squine de Macaraibo*) from Professor Guibourt, who found it in Caracas sarsaparilla.

6. **VERA CRUZ SARSAPARILLA** (*Radix Sarsaparillae de Vera Cruz*).—Much confusion exists about the sarsaparilla called the Vera Cruz sort; this name being usually applied to the gouty Caracas sort before described. The sort which I received some years ago under the name of "lean Vera Cruz sarsaparilla," I was
informed came from Vera Cruz; but it is now seldom met with. It is the sort which Mr. Pope\(^1\) described as "lean, dark, and fibrous." The bundle (Fig. 279) is 2 feet long, and, at the widest part, 7 inches broad: the weight is 7 ounces. The roots are unfolded (\textit{sarsaparilla longa}), and have the chump attached at one end.

![Bundle of Vera Cruz Sarsaparilla.](image)

They are thin, tough, of a grayish-brown colour, with a shrivelled, thin, non-mealy cortex. They give off very few rootlets. This sort yields a deep-coloured decoction, which is unchanged by a solution of iodine.

Vera Cruz sarsaparilla is the produce of \textit{Smilax medica}.

\textit{Tampico sarsaparilla} is probably identical with the Vera Cruz sort.

\textbf{Therapeutical Value and Quality.}—The relative therapeutical values of the different sorts of sarsaparilla are not easily determined. There are only two ways by which we can attempt to arrive at them—one chemical, the other clinical or empirical. But while, on the one hand, we have neither comparative analyses of the various commercial sorts of this root, nor an accurate knowledge of its active principle; so, on the other, we have no clinical observations of the relative effects of the different sorts, and great difficulty exists in the way of making them, on account of the immediate and obvious effects of this root being very slight. To this absence of actual precise information must be ascribed the different relative values assigned to the various sorts in different countries.

In the southern parts of Europe, where sarsaparilla has been the longest in use, the thickest and most mealy roots, irrespective of the country producing them, are preferred. It is, however, quite certain that starch is not the active principle of the root, but is regarded as being contemporaneous with it. I believe this opinion to be erroneous; for, 1stly, the mealy sarsaparillas give, to the test of oil of vitriol, slighter indications of the presence of smilacin than the non-mealy sorts; 2dly, the mealy sorts are the least acid to the taste; and, 3dly, the largest quantity of extract is obtained from a non-mealy sort, \textit{viz.}, that brought \textit{via} Jamaica.

In England the non-mealy sarsaparillas are almost universally, and, as I believe, properly preferred; and of these the Jamaica sort is most esteemed, and next to this, that called the Lima.

The colour of the root is not to be absolutely depended on, but roots having a deep orange-red tint are preferred. \textit{Taste}, perhaps, is the best criterion: the more acid and nauseous the taste, the better is the quality of the root. This test has been much insisted on by Dr. Hancock.\(^2\) The quantity of extract yielded by a given weight of the root has been much insisted on by Mr. Battley and Mr. Pope as a test of goodness; both these writers have asserted the superiority of Jamaica sarsaparilla, because it yields a larger quantity of extract. But though a sarsaparilla which yields very little extract cannot be regarded as good, yet it does not follow, especially in the absence of comparative trials, that a sarsaparilla which yields the most abundant extract is necessarily the best, since the quantity may arise from the presence of mucilage and other inert matters. The \textit{beard} is another criterion of goodness: the greater the quantity of root-fibres (technically called \textit{beard}), the better the sarsaparilla.

By cortical pith (Kinde Москем), the author obviously means the inner cortical layers.

² Syno de Mat. Med. B. v. 7, 1921
³ Journ. de Pharm. t. xx. p. 43, 1834
⁴ Pharmacisticum Central-Blatt für 1831, S. 892.
⁵ By epidermis, I presume the author means both epidermis properly so called and the outer cortical layers.

Vol. II.—15
1. **Essential Oil of Sarsaparilla.**—Sarsaparilla contains a small quantity of volatile oil. The following experiments were made by a friend, a manufacturing chemist, who gave me the products for examination. 140 lbs. of Jamaica sarsaparilla were distilled, by steam heat, at twice, with 220 gallons of water. 50 gallons of a milky liquid were obtained, which were again submitted to distillation until 20 gallons had passed over. 20 lbs. of common salt were added to the distilled product, and heat being applied, 3 gallons were drawn over. The liquor was milky, held in solution carbonate of ammonia, and contained a few drops of a volatile oil, which was heavier than water, was soluble in rectified spirit, and had the odour and acid taste of sarsaparilla. 100 lbs. of Jamaica sarsaparilla were distilled with 100 gallons of water. The distilled liquor was acid, and formed a white precipitate with solutions of acetate of lead. It was re-distilled: the liquor that first passed over was not ammoniacal, but towards the end of the process became so.

2. **Smilacin.**—Discovered in 1824 by Palotta, who termed it pariglia. Folchi, about the same time, also procured it, and gave it the name of smilacin. Thubuenp, in 1831, called it sasparin. In 1833, Batka announced that the active principle of this root was an acid, which he termed parallinic acid. Lastly, in 1834, Poggialep2 showed the identity of these different substances.

It is procured by decolorizing a concentrated hot alcoholic tincture of sarsaparilla by animal charcoal. The tincture deposits, on cooling, impure smilacin, which may be purified by repeated solution and crystallization. Soubeiranp3 has proposed a more economical process. It resides both in the cortical portion and in the woody zone.

Smilacin is a white, crystallizable, odourless, and, in the anhydrous state, almost tasteless substance: very slightly soluble in cold water, more so in boiling water, and depositing from the latter by cooling. Its solution has the bitter acid taste of sarsaparilla, and froths on agitation. It is soluble in alcohol, ether, and oils. It does not combine with acids to form salts. Strong sulphuric acid colours it red, then violet, and, lastly, yellow. It dissolves in cold and pure hydrochloric acid: the solution becomes red and afterwards gelatinous when heated. It is soluble in strong nitric acid: if the solution be heated, nitrous gas escapes; and, by evaporation, a solid residue is obtained, which is soluble in boiling water, from which it precipitates in white flocks as the liquid cools.

Smilacin is closely allied to, if it be not identical with, saponin. Now, as the latter is readily converted into an acid (esculetic acid), so probably is the former: hence, perhaps, the parallinic acid of Batka may not be absolutely identical with smilacin, but bear the same relation to it that esculetic acid does to saponin.

Smilacin has the following composition:

<table>

</table>

Poggiale gives the following formula for its atomic constitution, \( \text{C}_{10} \text{H}_{12} \text{O}_3 \); while O. Henryp4 assumes \( \text{C}_{10} \text{H}_{10} \text{O}_3 \), and Petersonp5 \( \text{C}_{10} \text{H}_{12} \text{O}_4 \). As no definite compound of smilacin has been obtained, these formulae are of little value. Thubuenp3 says that hydrated [crystallized] smilacin contains 8.50 water.

Cailleiriep6 gave it to nine syphilitic patients. In doses of six grains, the stomach readily supported it; but nine grains caused weight at the stomach and nausea. It appeared to relieve the patients’ symptoms, and, in one case, seemed to effect a cure. According to Palotta, pariglin, in doses of from two to thirteen grains, acts as a debilisant, reducing the circulation, sometimes producing constriction of the esophagus, and exciting nausea and diaphoresis. He thinks it might be useful in chronic rheumatism, skin diseases, &c.

3. **Starch.**—This is found in both the cortical and medullary cells. It is most abundant in the Caraccas, Brazilian, and Honduran sarsaparillas, to which it gives their mealy character. According to Schleiden, it exists in two forms—as grains and as paste.

The starch-grains are arranged in groups of 2, 3, 4, or 6; their shapes being modified by their mutual compression; the prevailing form being that of a mutilar. Their average length is about \( \frac{1}{2500} \) th of an inch.\(^7\) The nucleus (central cavity or hilum) is scarcely perceptible by ordinary light (Schleiden says that the grains are without evident central cavity); but the

---

1 Journ. de Pharm. x. 543.
3 Nouv. Traité de Pharm. ii. 166.

5 The following measurements, in parts of an English inch, of the grains of starch of sarsaparilla, were made for me by Mr. George Jackson.
6 Journ. de Chim. Méd. t. i. p. 45, 92bis.
7 Journ. de Pharm. xx. 282.
aid of polarized light its position may be determined, as it is at the junction of the arms of the cross. In some grains it can be detected by common light. Towards the circumference of some of the grains a series of faint parallel curved lines are observed.

Starch paste, or amorphous starch, is found in some of the cortical cells. It is more abundant in Vera Cruz sarsaparilla, which is sun-dried, than in the Brazilian sort, which has been dried by exposure to the smoke of fires; hence, probably, its formation depends on the season, and not on the action of heat on the grain starch. Iodine colours it blue. This so-called starch-paste, or amorphous state, is, perhaps, only imperfectly formed and closely aggregated starch grains.

4. Resin and Extractive.—These principles require further examination. On them probably depends a part, at least, of the medicinal properties of sarsaparilla.

Chemical Characteristics.—A decoction of sarsaparilla froths greatly when shaken. It scarcely, if at all, reddens litmus. Diacetate of lead and protonitrinate of mercury cause precipitates. Alkalies deepen the colour of the decoction.

If a strong decoction be added to oil of vitriol, a red colour is produced (owing to the action of the acid on the smilacin?).

Decoctions of mealy sarsaparilla become dark blue (iodide of starch) on the addition of a solution of iodine. Decoctions of non-mealy sorts are usually somewhat darkened by iodine, but the effect frequently disappears after a few minutes.

If a solution of a persalt of iron be added to the decoction, more or less darkening is usually produced. The greatest effect is produced with decoctions of either Jamaica or Lima sarsaparilla: with those of the Honduras and Brazilian sorts the effect is much feebler. In some cases a flocculent precipitate slowly subsides.1

If oil of vitriol be applied to a section of sarsaparilla, a greater or less portion of the woody surface (the woody zone, and, in the case of Jamaica and Lima sarsaparilla, the cortex also) becomes dark red, and then violet (owing to the action of the acid on the smilacin?). The same colour is also produced by the action of the acid on a fresh cut surface of the rhizome (chump).

If a strong decoction of mealy sarsaparilla be poured into alcohol, a copious precipitate (starch) is produced.

Physiological Effects. a. On Vegetables.—Not ascertained.

b. On Animals.—Not ascertained.

g. On Man.—Imperfectly determined; no experiments having been made to ascertain its physiological effects.

To the taste, sarsaparilla is slightly acid, and somewhat nauseous. Diaphoresis is by far the most common effect of its internal use. When the skin is kept cool, diuresis is not unusual. But in estimating the diaphoretic or diuretic power of sarsaparilla, we must take into consideration the amount of liquid in which the medicine is usually taken, and the other medicines which are frequently conjoined with it: for, in many instances, the diaphoresis or diuresis is referable rather to these than to sarsaparilla.

In several cases I have given the powder of this root in very large doses, in order to ascertain its effects. Nausea, vomiting, and temporary loss of appetite, were alone observed.

Dr. Hancock2 says, that on one patient, an African, an infusion of four ounces of Rio Negro sarsa acted as a narcotic, producing nausea, great prostration of strength, torpor, and unwillingness to move. The pulse was scarcely altered, unless

The bulk of this specimen consisted of particles of the size of those distinguished by an asterisk. One of the hemispherical or multiform-shaped particles measured 0.0007 by 0.0005.

A compound grain, consisting of three grains, was found to be 0.0005 in diameter.

1 See, also, Marquart's comparative examinations of several kinds of sarsaparilla, in the Pharmaceutical Journal, vol. lii., p. 138, 1843.

it were a little retarded. Though the effects here stated agree, to a certain extent, with those ascribed to smilacin, they cannot be regarded as the ordinary effects of this root.

In some conditions of system, especially those of a cachectic kind, sarsaparilla acts as a powerful and valuable alterative tonic. Its continued use is often attended with improvement of appetite and digestion, augmentation of strength, increase of flesh, the production of a more healthy tone of mind, and the palliation, or, in some cases, complete disappearance, of various morbid symptoms—as eruptions, ulcerations, pains of a rheumatic character, &c. Sarsaparilla differs in several respects from the bitter vegetable tonics. Though it is not devoid of, yet it does not, as they do, abound in a bitter principle. It is not adapted for the cure of intermittents, or of simple debility. But its best effects are seen in those depraved conditions of system, which the public, and even some medical men, ascribe to the presence of a morbid poison, or to a deranged condition of the fluids. Hence it is frequently denominated a purifier of the blood. Those who do not adopt the pathological notion here referred to, call it an alterative.

Those varieties of sarsaparilla which abound in starch (as the Caraccas and Honduras sorts) possess demulcent and nutritive properties.

Uses.—By many practitioners sarsaparilla is considered to possess no remedial properties; by others it is regarded as a medicine of great efficacy. Considering that more than 100,000 lbs. of it are annually consumed in this country, the number of those who entertain the latter opinion cannot be small. It has been justly remarked by Mr. Lawrence, that physicians have no confidence in it, and surgeons a great deal. I think that this fact is readily explained by the circumstance that physicians are much less frequently called in to prescribe for those forms of disease in the treatment of which surgeons have found sarsaparilla so efficacious.

Many practitioners have doubted or denied its remedial activity on what, it must be admitted, are very plausible grounds; viz., that the root possesses very little taste and no smell; that, by the ordinary mode of using it, it produces very slight, if any, obvious effects on the animal economy; and that it has failed in their hands to relieve or cure diseases in which others have asserted they found it effectual. They are, therefore, disposed to refer any improvement of a patient's health, under the long-continued use of sarsaparilla, either to natural changes in the constitution, or to the influence of the remedial means with which the sarsaparilla was conjoined. But I would observe, that hitherto no experiments have been made to ascertain what effects the long-continued employment of sarsaparilla may give rise to in the system of a healthy man; and we are not warranted in assuming that none would result, because none are observable from the employment of a few doses. Moreover, it is to be remembered that some of our most powerful poisons prove the most efficacious remedies when given in such small doses that they excite no other obvious effect on the system than the removal of morbid symptoms. Witness the beneficial influence of the minute doses of arsenious acid in leprosy. Furthermore, no one has ascribed to sarsaparilla the power of a specific, and its warmest advocates admit its occasional failure. But so often has it been found, that various diseases, which had resisted all other tried remedial means, and were gradually increasing, became stationary, and afterwards subsided, under the use of sarsaparilla, that a large majority of British surgeons, including the most eminent of the present day, have been compelled to admit its therapeutic power.

As no obvious relationship exists between its known physiological effects and its apparent therapeutic agency, an argument has been raised against its medicinal activity, on the ground that we cannot explain its methodus medendi; but, for the same reason, we might refuse to admit the power of cinchona to cure ague. Mr.  

Sarsaparilla:—Uses.

Lawrence justly observes that, although we cannot point out the manner in which a remedy operates, we are not, on that account, to withhold our confidence in its power. It is enough for us, in medical science, to know that certain effects take place. In point of fact, we are in many cases unable to distinguish the modus operandi of medicines—the manner in which their influence is produced. The most plausible explanation of the agency of alterative medicines is that offered by Müller, and which I have before had occasion to notice (see vol. i. p. 137). It assumes that these remedies cause changes in the composition of the nutritive fluids (the chyle and blood), and thereby produce slight chemical alterations in organs morbidly changed in composition, by which already existing affinities are annulled, new ones induced, and the vital principle enabled to effect the further restoration and cure. This hypothesis may be used to explain the remedial influence of sarsaparilla.

Sarsaparilla has been found especially serviceable in the following maladies:—

1. In invertebrate venereal disease.—It is beneficial principally when the malady is of long continuance, and the constitution is enfeebled and emaciated, either by the repeated attacks of the disease, or by the use of mercury. In such cases it is, as Sir William Fordye correctly observed, "the great restorer of appetite, flesh, colour, strength, and vigour." When the disease resists, or is aggravated by, the use of mercury, sarsaparilla evinces its most salutary powers. It is given to relieve venereal pains of a rheumatic character; to remove venereal eruptions; to promote the healing of ulcers of the throat; and to assist in the cure when the bones are affected. In recent chancre, or bubo, it is of little use; nor does it appear to possess the least power of preventing secondary symptoms. We cannot ascribe to it "the same anti-syphilitic properties—that is, the same power of arresting or curing the venereal disease—that experience warrants us in attributing to mercury."

Sarsaparilla is sometimes given alone, but more frequently with other remedies: as with stimulating diaphoretics (mezereum, sassafras, and guaiacum), or with mercurials in small or alterative doses, or with acids (especially the nitric), or with alkaline substances (as potash or lime), or with iodine or with the bitter tonics. It is difficult to lay down concise rules to guide us in the selection of these adjuncts. In venereal pains and eruptions, sudorifies, the copious use of warm diluents and warm clothing, are especially applicable, and should be conjoined with sarsaparilla. In serofulous constitutions, with enlarged glands, it will be for the most part advisable to avoid the use of mercury. In such I have seen the alkalies most serviceable. When extreme debility is present, the bitter tonics and nitric acid are often added to sarsaparilla with benefit. When the periostea is affected, iodide of potassium should be conjoined.

2. In chronic rheumatism sarsaparilla is often advantageously conjoined with powerful sudorifies and anodynes (as opium or hyoscyamus), especially when any suspicion exists as to the venereal origin of the disease.

3. In obstinate skin diseases benefit is frequently obtained by the use of sarsaparilla. Its employment is not confined to cutaneous affections of one particular elementary form, since it is given with good effect in papular, vesicular, pustular, and tubercular skin diseases, of a chronic kind, when they occur in enfeebled and emaciated constitutions. Though, in these cases, its value principally depends on its tonic and alterative effects, its diaphoretic operation is to be encouraged by the use of diluents, warm clothing, &c.

4. In cachectic conditions of the system generally, sarsaparilla may be given, often with the best effects, and never with any ill consequences, save that of producing slight nausea. Indeed, one of the great advantages of sarsaparilla over many other alteratives and tonics, is, that although it may fail in doing good, it never does any

2 Medical Observations and Inquiries, vol. i.; p. 169.
3 Lawrence, op. cit. p. 769; see, also, Mr. Pearson's Observations on the Effects of various Articles of the Materia Medica in the Cure of Venereal Disease, p. 39, 1860.
harm beyond that of now and then causing slight disorder of stomach. In chronic abscesses, attended with profuse discharge, diseases of the bones, obstinate ulcers, chronic pulmonary affections accompanied with great wasting of the body, enlarged glands, and various other maladies connected with a depraved state of the system, sarsaparilla is often a very useful medicine.

**Administration.**—Sarsaparilla is administered in substance, and in the form of infusion, decoction, extract, and syrup.

1. **Pulvis Sar** Sæ; *Powdered Sarsaparilla.*—The ordinary dose of this is from half a drachm to one or two drachms. Half an ounce frequently nauseates, and in some cases gives rise to vomiting. Powder of Jamaica sarsaparilla is to be preferred to that of other varieties. It is redder than that of the Honduras kind, and produces a much less intense blue colour when rubbed with water and tincture of iodine. I have been informed that some druggists employ, in the preparation of the powder, the roots from which the extract has been prepared. This fraud may be detected by the powder being almost devoid of taste, macerating it in water, and carefully comparing the infusion with one prepared from an unadulterated sample. The microscope might sometimes be carefully employed to detect adulterations of powdered sarsaparilla. The presence of foreign starch grains would indicate the presence of some other vegetable in the suspected powder. [2. **Infusum Sarsaparillæ** U. S.].—Take Sarsaparilla, bruised, an ounce; Boiling Water a pint. Digest it for two hours in a covered vessel or strain, or by displacement.

3. **Decoctum Sar** Sæ, L. E.; *Decoction Sarsaparillæ, D.*; *Decoction of Sarsapa- rilla.*—(Sarsa, sliced [in chips, E.], 3v [3ij, D.]; Boiling Water Oiv [Oiss, D.]. Boil down to two pints, and strain. ["The product should measure a little more than a pint," D.])—An objection has been taken to this, as well as to all preparations of sarsaparilla made by boiling, that the heat employed volatilizes or decomposes the active principle of the root. "An infusion of sarsaparilla," says Soubeiran, 4 "which is odorous and sapid, loses both its odour and taste by boiling for a few minutes: these changes speak but little in favour of the decoction. On the other hand, it is known that the fibrous parts of vegetables always give less soluble matters to water, when treated by decoction; and if it be added that sarsaparilla is completely exhausted by hot water, I cannot see what advantages the decoction can possess over preparations made by other methods." Without denying the injurious effects of long boiling, and, therefore, the superiority of preparations made without it, I cannot admit that either the decoction or extract of sarsaparilla is inert. No objection, however, exists to the substitution of an *infusion* for a decoction. But it is advisable to employ a somewhat larger quantity of the root, and to have it crushed before macerating it. The proportions of root and water, in the above preparation, are such that one ounce of the decoction contains the extractive of one drachm only of the root. Hence the extract or syrup is usually conjoined.

Mr. Jacob Bell 5 objects to taking out the roots after maceration, in order to bruise them, on the ground that by this process the wood may absorb a larger portion of the virtues of the bark in return for the inert starch which it gives out.

An infusion or decoction of Jamaica sarsaparilla usually produces little or no blue colour with tincture of iodine; whereas the corresponding preparations of Honduras sarsaparilla (the kind usually met with, cut in small split lengths, in the shops) becomes bluish black on the addition of a solution of iodine. The dose of *Decoction Sar* sæ is f 3iv to f 3vij three or four times daily.

4. **Decoctum Sar** Sæ Compositum, L. E.; *Decoction Sarsaparillæ Compositum, D.* [U. S.]; *Compound Decoction of Sarsaparilla.*—(Decoction of Sarsaparilla, boiling hot, Oiv; Sassafras sliced and bruised, Guaiacum-wood shavings, Liquorice-root bruised, of each 3x; Mace reson [bark of the root], 3ij [3s, E.]. Boil for a

---

quarter of an hour and strain.—The Dublin College orders of Sarsaparilla Root, sliced, 3 ij.; Sassafras Root in chips, Guaiacum wood turnings, Liquorice Root bruised, of each 5 ij.; Mezereon root-bark 5 j.; Boiling Water Oiss. Digest for one hour, then boil for ten minutes, cool and strain. The product should measure a little more than a pint.—[The U. S. Pharm. orders of Sarsaparilla, sliced and bruised, six ounces; Bark of Sassafras root sliced, Guaiacum wood rasped, Liquorice root bruised, each an ounce; Mezereon, sliced, three drachms; Water, four pints. Boil for a quarter of an hour, and strain.]—This preparation is an imitation of the celebrated Lisbon Diet Drink. The objections made to the use of ebullition in preparing the simple decoction apply equally to the present preparation. The additions are for the most part valueless. The guaiacum-wood is useless, water not being able to dissolve the resin. The volatile oil contained in the sassafras-wood is in part dissipated by the boiling. The mezereum, an active agent, is used in such small quantity that it can confer but little medicinal power. Moreover, these acids are apt to disorder the stomach. The liquorice is employed merely to communicate flavour. An improvement in the present formula would be to omit the guaiacum, to increase the quantity of sarsaparilla and mezereum, to substitute maceration for decoction, and to add oil of sassafras. The dose of the official preparation is from f 3/4 to f 3/4 three or four times a day. The syrup or extract is usually conjoined with it. During its use the skin should be kept warm.

A Liquor Sarsae compositus concentratus is usually kept in the shops for the extemporaneous preparation of the compound decoction of Sarsaparilla.

§. SYRUPUS SARSÆ, L. E.; Syrupus Sarsaparillae; Syrup of Sarsaparilla.—(Sarsa 1biijs; Distilled Water Cong. iij; Sugar 3 xij; Rectified Spirit f 3/4j. Boil the sarsa, in two gallons of the water, down to one gallon; pour off the liquor, and strain it while hot. Again boil the sarsa in the remaining water down to one-half. Evaporate the mixed liquors to two pints, and dissolve the sugar in them. Lastly, when cold, add the Spirit, L.—The Edinburgh College orders of Sarsa, in chips, 3 xv; Boiling Water Cong. j; Pure Sugar 3 xv.)—Simonin has successfully prepared the syrup by the percolation method.

This I conceive to be a very unnecessary preparation; for, as the late Dr. A. T. Thomson⁸ justly observes, "it can be much better and more easily supplied by rubbing up a few grains of the extract with some simple syrup." It is, however, frequently prescribed as an adjunct to the decoction. Prepared with Jamaica sarsaparilla, it is not liable to fermentation, and its flavour is somewhat agreeable, being very analogous to that of West India molasses. Mr. Brande⁹ says that, to be an effective form of sarsaparilla, it ought to be of such strength that one ounce is equal to a pint of the simple decoction. Of this, f 3/4s or f 3/4 may be taken two or three times a day, diluted with about two parts of water. A few drops of solution of potassa sometimes prevent its disagreement with the stomach.

The Syrup of Sarsaparilla of the United States Pharmacopoeia is intended to represent the famous French Sirop de Cuisinier. It is prepared with proof spirit, which extracts the acrid principle of the root without taking up the ineret fecula; and the tincture being evaporated, to get rid of the alcohol, is made into syrup. By this means the long-continued boiling is avoided. As the editors of the United States Dispensatory speak most confidently of the remedial value of this preparation, I subjoin the formula for its preparation, taken from the American Pharmacopoeia:

**Compound Syrup of Sarsaparilla [Syrupus Sarsaparillae Compositus]. U.S.—** Sarsaparilla, bruised, 3 ij.; Guaiacum wood, rasped, 3 xij; Red Roses, Senna, Liquorice-root, bruised, each 3 ij.; Oil of Sassafras. Oil of Anise, each m.v; Oil of Partridge-berry [Gaultheria procumbens, an astringent aromatic] M ij.; Sugar Baviij; Diluted Alcohol Ox [seine mesure]. Macerate the sarsaparilla, guaiacum wood, roses, senna, and liquorice root, in the diluted alcohol for fourteen days; then express and filter through paper. Evaporate the tincture, by means of a water-bath, to four pints

and a half; then add the sugar, and dissolve it so as to form a syrup. With this, when cold, mix the oils, previously triturated, with a small quantity of syrup." The dose is 3 s (equivalent to somewhat less than 1/2 of the root), taken three or four times a day.

A Syrupus Sarsae compositus is usually kept in the shops.

### 6. EXTRACTUM SARSÆ LIQUIDUM, L.; Extractum Sarsae fluidum, E.; Extractum Sarsaparillae fluidum, D. [U. S.]; Fluid Extract of Sarsaparilla, Offic.—(Sarsa ibijss; Distilled Water Cong. v; Rectified Spirit 3ij, L.—Sarsa, in chips, ibi; Boiling Water Ovi, E.—Sarsaparilla ibij; Boiling Water Oviij; Rectified Spirit as much as is sufficient, D.—Boil the sarsa in three gallons of water down to twelve pints; pour off the liquor, and strain while hot. Again boil the sarsa in the remaining water to half, and strain. Evaporate the mixed liquors to 5xvij, and when the extract has become cold add the spirit to it, L.—"Digest the root for two hours in four pints of the water; take it out, bruise it, replace it in the water, and boil for two hours; filter and squeeze out the liquid; boil the residuum in the remaining two pints of water, and filter and squeeze out this liquor also; evaporate the united liquors to the consistence of thin syrup; add, when the product is cool, as much rectified spirit as will make in all sixteen fluidounces; filter. This fluid extract may be aromatized at will with various volatile oils or warm aromatics," E. The U. S. Pharm. orders of Sarsaparilla, sliced and bruised, sixteen ounces; Liquorice root bruised, Root of Sassafras bruised, each two ounces; Mezereon, sliced, six drachms; Sugar, twelve ounces; Diluted Alcohol, eight pints. Macerate all of the ingredients together, excepting the sugar, for fourteen days; then express and filter. Evaporate the liquid, by means of a water-bath, to twelve fluidounces; add the sugar to it while still hot; and remove it from the bath as soon as the sugar is dissolved."

In this country, Jamaica sarsaparilla is preferred for the preparation of the extract; and next to this the Lima sort. If Honduras, or any other mealy sarsaparilla be employed, the product contains a large quantity of starch-gum. Extract of Jamaica sarsaparilla, when rubbed on white paper or porcelain, exhibits a reddish tint not observable in the extract of the Honduras kind. The flavour and odour are characters which assist in distinguishing well-prepared extract. Rubbed up with water, it is almost completely soluble, and the solution, which should be clear, by standing scarcely deposits anything. The dilute solution should not remain blue on the addition of a solution of iodine. But extract prepared from a mealy sarsaparilla does not completely dissolve in water, and yields a turbid liquor, which becomes dark blue on the addition of a solution of iodine.

In England the fibrils or beard of Jamaica sarsaparilla are preferred to both root and rhizome (chump). They contain less starch and woody fibre than the latter, and they yield a greater proportion of extract.

The quantity of extract obtained from Jamaica sarsaparilla has already been alluded to (see ante, p. 270). The following table is from the papers of Thu-beuf:—

Extract made by the evaporation of an infusion prepared by the displacement process is devoid of starch, and is consequently richer in the active principles. By the avoidance of ebullition, the destruction or dissipation of volatile matters is less likely to be effected.

---

In effecting the evaporation of the decoction or infusion, steam heat should be employed; and the temperature of the liquid should not be allowed to exceed 212° F.

When the concentrated decoction (especially of the Honduras kind) is allowed to cool, as at night, a kind of fermentation is readily set, and gas is copiously evolved.

Extract of sarsaparilla, when it has been kept for some time, frequently becomes covered by cubical crystals of chloride of potassium.

It deserves notice that though smilacin is said to be soluble in boiling alcohol and ether, yet I find that the extract of Jamaica sarsaparilla yields but little to these liquids.

Extract of sarsaparilla is declared by many writers to be an inert and useless preparation; but the assertions are, for the most part, founded rather on theoretical than practical considerations. I have extensively used it, and believe that, when properly prepared from Jamaica or Lima sarsaparilla, it is a most valuable and efficient remedy; and the enormous quantity of it which is consumed by the profession generally (including some of the most eminent of its members), is a proof that many others entertain a similar opinion of it. It is given in doses of from half a drachm to two or three drachms three or four times a day. It should be rubbed down with water, and flavoured by the tincture of orange-peel, or by some volatile oil (as the oil of cloves, allspice, lemon, or cinnamon). Alkalies render its flavour somewhat disagreeable, though they frequently increase greatly its remedial powers.

7. EXTRACTUM SARSAPIRILLAE COMPOSITUM; Compound Extract of Sarsaparilla.—Not in any Pharmacopoeia, though kept in the shops. It is made by mixing, with extract of sarsaparilla, an extract prepared by evaporating a decoction of mezereon bark, liquorice root, and guniacum shavings, to which a small quantity of oil of sassafras has been added. This preparation is employed as a convenient substitute for the compound decoction of sarsaparilla. The dose of it, and the mode of exhibition, are the same as of the simple extract. Three-quarters of an ounce of the compound extract are equal to a pint of the compound decoction.

98. Smilax China, Linn.

(Radix.)

Smilax China, Kümplf. Ameen. Exot., p. 783; Loureiro, Fl. Cochinchinensis, p. 622.—A native of Japan, China, and Cochín China.—The China root of the shops (radix China orientalis seu tere vel ponderosae) is said to be the produce of this species. But, according to Roxburgh,¹ the roots of S. glabra and S. lanceolata, which are used in the East in medicine, are not to be distinguished by the eye from the roots of S. China, brought from China.

China root is imported into England, usually in baskets, from Calcutta and Singapore. Dr. O'Shaughnessy² states that it is largely imported into Calcutta from the eastward. It is said to be the produce of the province of Onansi, in China. It occurs in large, ligneous, knotty pieces, of from three to eight inches long, and an inch or two thick. Externally it has a greyish-brown colour, and internally a light flesh or yellowish-white colour. It is inodorous, and has a slightly astringent taste.

It has been analyzed by Reinsch,³ who found it to consist of wax 0.3, balsamic resin 0.4, crystalline matter (smilacin) 2.8, with sugar, tannic acid, salts, and resinous colouring matter (quantity not stated), tannic acid with salts, reddish gummy colouring matter, and smilacin 4.8, starch-gum, vegetable gluten, and salts 2.6, starch 23.5 with salts, starch with tannic acid 34.0, woody fibre 20.0, and water 12.0 (±0.4).

It was introduced into Europe, in 1535, as an infallible remedy for the venereal disease, and obtained great celebrity in consequence of the benefit which the Emperor Charles the Fifth is said to have derived from it in gout. Its effects are not very obvious, but it is said to be diaphoretic. It tingles the sweat. It has been used in the same maladies as sarsaparilla, viz., venereal diseases, rheumatism, gout, obstinate skin diseases, &c. It is given in the form of decoction.

¹ Fl. Indiae, vol. iii. p. 798.

³ Bengal Dispensatory.
SPURIOUS CHINA ROOTS.—Several smilaceous roots, the produce of the New World, but resembling the oriental China root, have been described under the name of American or occidental China root (radix China Americana vel occidentalis). Their origin is by no means well ascertained, though they are usually said to be the produce of Smilax Pseudo China, Linn. Hernandez notices three sorts: one which he calls Oleacutsan or Mexican China root; a second termed Pharo; and a third called Cozolmealt.

One or more sorts of occidental China root are frequently found in the middle of the bundles of Lima and some other kinds of sarsaparilla (see ante, p. 271).

Brazilian China root, known by the various names of Juapecanga, Inhopecanga, Jupicanga, Jupicanga, and Raiz de China branca vel rubra, is obtained from several species of Smilax: viz., S. Jupicanga, Grisebach; S. syringoides, Grisebach (Jupicanga, Piso, Med. Braz. i. 99); S. Brasilienis, Grisebach (S. glauca, Martius, Reise, i. 283); and S. siphilitica, Humboldt. It has not been analyzed. Its uses resemble those of oriental China root.2

99. Smilax aspera, Linn.
(Radix.)

Smilax tracya, Dioscorides, lib. iv. cap. 144. Smilax, Pliny, lib xvi. cap. 63.—A native of the South of Europe. Its roots constitute Italian sarsaparilla (Sarsaparilla italicca). They have not been analyzed. Their effects, uses, and mode of administration resemble those of the ordinary sarsaparilla brought from America.3

The roots of Hemidesmus indicus, or Indian sarsaparilla, are frequently sold in London under the name of Smilax aspera. They will be noticed hereafter.

Class IV. Exogena, D.C.—Exogens.  

Dicotyledones, Jussieu.

Characters—Trunk, consisting of bark, wood, and pith, placed one within the other, the pith being innermost. Bark, composed of strata (the younger and inner being called endophleum or liber), each usually increasing by the deposit of new matter on its inner side. Wood, consisting of ligneous strata, traversed by medullary rays, and increasing by the deposit of new woody matter on its outer side (exogenous growth); the older and inner strata are called duramen, or heart wood; the younger and outer strata are termed alburnum, or sap wood. Leaves usually articulated with the stems; their veins commonly branching and anastomosing (netted, reticulated). Flowers, if with a distinct calyx, often having a quinia, sometimes a quaternary, rarely a ternary arrangement. Embryo with two or more coryledons (dicotyledonous); if two, they are opposite; if more than two (polycotyledonous), they are verticillate, radicle naked, i. e. elongating, without penetrating any external case (exorhizous).

This class includes two sub-classes: 1. Gymnospermae, or naked-seeded exogens; 2. Angiospermae, or covered-seeded exogens.

Sub-class I. Gymnospermae.—Gymnosperms.  

Gymnogens, Lindl.

Characters—Ovules naked, in an open carpellary leaf or pervious disk, fertilized by direct application of the pollen to the foramen (micropyle) without the intervention of stigma, style, and ovary. Ligneous tissue porous at the sides, the pores being apparently surrounded each by one or two circles.

This sub-class includes two orders: 1. Cycadee, or Cycads; 2. Pinaceae, or Conifers.

2 For a figure and description of Brazilian China root, see Goebel and kunze’s Pharmaceutische Warenkunde, Bd. ii. S. 129, Taf. xviii. Fig. 2.
3 For further details respecting the medicinal properties of Smilax aspera, see Mirat and De Lasa, Diet. Univ. de Mat. Méd. i. vi. p. 371, 1831; and Dierbach’s Neuest. Entdeck. in d. Mat. Med. Bd. iii. Abt. ii. S. 1068. 1847.
ORDER XXI. CYCADACEÆ, Lindl.—CYCADS.

Cycadæm, Richard and R. Brown.

Characters.—Gymnosperms with a simple continuous stem, parallel-veined pinnate leaves, and scales of the cone antithomorphic.

Properties.—Mucilage and starch are the useful products of this order. They are found in the stems and seeds (see Cycas and Zamia). The seeds of Dion edule yield a starch which is used in Mexico as arrow-root. (Lindley.)

100. Cycas, Linn.

Sex. Syst. Dicæa, Polyanthriæ.

No product of this genus is employed in Europe, either as medicine or food. From the stems of C. circinalis and C. revoluta a starch is obtained, of which a kind of sago is said to be made in the East. I have prepared starch from both of these species, and find that its microscopic characters are entirely different from those of the sago starch of European commerce. The starch of C. circinalis consists of grains united in masses of from 2 to 6: the single grains are rendered more or less irregular or polygonal by their mutual compression, but hemispherical and muller-shaped particles predominate. Their size varies, but is on the average smaller than that of the starch grains of genuine sago. The so-called hilum frequently appears split and surrounded by rings. In polarized light the grains show a distinct cross.—The starch of C. revoluta, of which Japan sago is said to be made, resembles that of the preceding species. None of it comes to England. The Dublin Pharmacopœia, 1850, states that sago is the farina of the interior of the trunk of Cycas circinalis, and also of other species of Cycas, and various Palmaeæ. The facts, however, are as I have stated them.—A clear mucilage, which concretes into a gum like tragacanth, exudes from fresh-wounded parts of several species of Cycas. 1

101. Zamia, Linn.

Sex. Syst. Dicæa, Polyanthriæ.

In the Bahamas, and some other of the West India Islands, a starch is obtained from the trunk of some species of this genus, which is employed as an excellent sort of arrow root. None of it, to my knowledge, comes to Europe as an article of commerce. In the Museum of Economic Botany, at the Botanic Garden, Kew, there is a specimen of a starch, sent from Jamaica by Mr. Purdie, and stated to be “A nutritious powder made from the trunk of Zamia integrifolia, and sold in the West India Markets.” In external appearance it resembles West Indian Arrow-root (Maranta arundinacea): but when examined by the microscope it is found to consist of rather large-sized grains, 2 some of which are spheroidal; but most of them are the

1 The following measurements, in parts of an English inch, of the starch of C. circinalis, were made for me by Mr. George Jackson:

separated parts of compound grains, and, therefore, are variously shaped, owing to their mutual compression; some being hemispheres, others muller-shaped grains, &c. The nucleus and rings are scarcely discernible. Most of the grains present a superficial protuberant scar (like the hilum of some seeds), the situation of which is remote from the nucleus (as ascertained by polarized light).

[Zamia Medica.—This is an intermediate species between Z. integrifolia and Z. angustifolia. It differs from the former in having more numerous, longer, and narrower leaflets, which are perfectly entire, or nearly destitute of the serratures at the apex. The footstalk is hairy at base, and the female cone is obsolete, not pointed. Specimens have been brought to me from Florida by Dr. Gorton, of the U. S. Navy, which agree with those, from the same locality, in the Herbarium of the Academy of Natural Sciences.

The root of this plant is a large spheroidal or somewhat tapering coated tuber, rough and dark-coloured externally, fleshy, internally white and succulent, and, when incised, peering forth a fluid of gummy consistence, which hardens in small tears at the point of exit. This root is called cooni root in Florida by the Indians and white settlers, and the farina prepared from it is also called cooni. As a nutriment, it is found in the shops of the northern cities of the United States, under the name of Florida arrow root. When carefully prepared, it has a mealy appearance and feel, is of a pure white colour, and somewhat of a lustrous appearance; it is apt to be lumpy. The mode of preparation is the same as that of Bermuda arrow root. The form of the granules is that of the “half, fourth, or third of a solid sphere.” Some of the granules are completely muller-shaped, in fact the form is exactly that which is given by Raspail for the granule of the Maranta Arundinacea, which is invariably round.

Florida arrow-root is employed for the same purposes and in the same manner as the other species of farina in use.—J. C.]

Order XXII. Pinaceæ, Lindley.—Conifers.

Characters.—Flowers monocious or dioecious, naked. Males monandrous or monadelphous; each floret consisting of a single stamen, or of a few united, collected in a deciduous amentum; about a common rachis; anthers 2-lobed or many-lobed, bursting longitudinally; often terminated by a crest, which is an unconverted portion of the scale out of which each stamen is formed. Females in cones. Ovary spread open, and having the appearance of a flat scale destitute of style or stigma, and arising from the axil of a membranous bract. Ovule naked; in pairs or several, on the face of the ovary, inverted, and consisting of one or two membranes, open at the apex, together with a nucleus. Fruit consisting of a cone formed of the scale-shaped ovaries, become enlarged and indurated, and occasionally of the bracts also, which are sometimes obliterated, and sometimes extend beyond the scales in the form of a lobed appendix. Seed with a hard crustaceous integument. Embryo in the midst of fleshy, oily albumen, with 2 or many opposite cotyledons; the radicle next the apex of the seed, and having an organic connection with the albumen.—Trees or shrubs, with a branched trunk abounding in resin. Wood with a ligneous tissue marked with circular disks. Leaves linear, acerose or lanceolate, entire at the margins; sometimes fascicled in consequence of the non-development of the branch to which they belong; when fascicled, the primordial leaf to which they are then axillary is membranous, and encrusted them like a sheath. (Lindley.)

Properties.—Every part of coniferous plants contains an oleo-resinous juice, which, by distillation, is resolved into volatile oil and resin. The medicinal properties of this juice have been before noticed (see vol. i. pp. 254–255).

Sub-order I. Abietæ.

Ovules inverted; pollen oval, curved.

102. Pinus, DC.—The Pine.

Sex. Syst. Monoeic, Monadelphia. (Oleo-resinus.)

Botany. Gen. Char.—Flowers monocious. Males:—catkins racemose, compact and terminal; squamos; the scales staminiferous at the apex. Stamens 2; the anthers 1-celled. Females: catkins or cones simple, imbricated with acuminate scales. Ovaries 2. Stigmas glandular. Scales of the cone oblong, club-shaped, woody; umbilicato-angular at the apex. Seeds [nuts, DC.] in pairs, covered with
THE PINE:—its SPECIES.—THE FIR.

285

**Species.**—1. *Pinus sylvestris*, Linn.; *Wild Pine or Scotch Fir.*—*Leaves* in pairs, rigid. *Cones* ovato-conical, acute; young ones stalked, recurved, as long as the leaves; generally in pairs. Crest of the *anthers* very small. *Embryo* 5-lobed (*Bot. Gall.*).—Highlands of Scotland, Denmark, Norway, and other northern countries of Europe. Flowers in May and June. A tall, straight, hardy, long-lived tree, determinately-branched. Its wood is the red or yellow deal. It yields *common turpentine, tar, and pitch.*

2. *Pinus Pinaster*, Aiton, Lambert; *P. maritima*, DC.; *the Pinaster or Cluster Pine.*—*Leaves* twin, very long, rigid, pungent, furnished at the base with a reflected scale. *Cones* oblong-conical, obtuse, very smooth, bright, shorter than the leaves. *Scales* bristly (*Bot. Gall.*).—Southern maritime parts of Europe. Very abundant in the neighbourhood of Bordeaux, and between this city and Bayonne. It is a much larger tree than the Scotch Fir. Flowers in May. It yields *Bordeaux turpentine, galipot, tar, and pitch.*

3. *Pinus Palustris*, Lambert; *the Swamp Pine.* *Leaves* 3, very long. *Cones* subcylindrical, armed with sharp prickles. *Stipules* pinnatifid, ragged, persistent (Lambert).—A very large tree, growing in dry sandy soils, from the southern parts of Virginia to the Gulf of Mexico. "Its mean elevation is 60 or 70 feet, and the diameter of its trunk about 15 or 18 inches for two-thirds of this height. The leaves are about a foot in length, of a brilliant green colour, and united in bunches at the ends of the branches. The names by which the tree is known in the Southern States are long-leaved pine, yellow pine, and pitch pine; but the first is the most appropriate, as the last two are applied also to other species. This tree furnishes by far the greater proportion of turpentine, tar, &c., consumed in the United States, or sent from this to other countries."1

4. *Pinus Taeda*, Lambert; *the Frankincense Pine.*—Abundant in Virginia. Yields *common turpentine*, but of a less fluid quality than that which flows from the preceding species.

5. *Pinus Pinea*, Lambert, DC.; *the Stone Pine.*—Grow* s in the south of Europe and northern part of Africa. Called, in the shops, *pignoli pines*, the seeds of which, termed *pine nuts* (πεπερίδας, Diosc.; *pityida*, Pliny; *nucli pinic pinned*), are used as a dessert.

6. *Pinus Pumilio*, Lambert; *the Mugo or Mountain Pine.*—A native of the mountains of the south of Europe. An oleo-resin, called *Hungarian balsam* (*Balsamum Hungarianicum*), exudes spontaneously from the extremities of the branches, and from other parts of the tree. By distillation of the young branches with water, there is obtained in Hungary an essential oil, called *Krumholzöl*, or *oleum tentialinum*.

7. *Pinus Cembra*, Lambert, DC.; *the Siberian Stone Pine.*—The seeds, like those of Pinus Pinea, are eaten. By distillation the young shoots yield *Carpathian balsam* (*Balsamum carpathicum*; b. *Libani*).

103. *Abies, DC.—THE FIR.*

*Sex. Syst. Monoeica, Monadelphus.*

(Oleo-resine.)

**Botany. Gen. Char.**—*Flowers* monoecious. **MALES:** *catkins* solitary, not racemose; the *scales* staminalferous at the apex. * Stamens* two; the *anthers* 1-celled. **FEMALES:** *catkins* simple. *Ovaries* 2. *Stigmas* glandular. *Scales* of the *cone* imbricated; thin at the apex, rounded (neither thickened, angular, nor umbilicated on the back). *Cotyledons* digitato-partite. *Leaves* solitary in each sheath (*Bot. Gall.*).

1 United States Dispensatory.
Species.—1. Abies excelsa, DC.; A. communis, Hort.; Pinus Abies, Linn.; the Norway Spruce Fir.—Leaves tetragonal. Cones cylindrical; the scales rhomboid, flattened, jagged, and bent backwards at the margin (Bot. Gall.)—A native of Germany, Russia, Norway, and other parts of Europe; also of the northern parts of Asia. Commonly cultivated in England. Flowers in May and June. A very lofty tree, growing sometimes to the height of 150 feet. It yields by spontaneous exudation common frankincense (abietis resina; thus, L. D.), from which is prepared Burghundy pitch, D. (pix burgundica, L. E., pix abietina).

The leaf-buds (gemmae seu turiones abietis) of this species of Abies, as well as of the Silver Fir (Abies Picea), are used on the continent, in the form of decoction or beer; or, with the woods of guaiacum and sassafras, and juniper berries, in the form of tincture (tinctura pini composita, Pl. Ber.). They are employed in scouring, rheumatic, and gouty complaints.

3. Abies canadensis, Lindley; Pinus canadensis, Linn., Lambert; the Hemlock Spruce Fir.—Said to yield an oleo-resin analogous to Canada balsam.

4. Abies Picea, Lindley; Abies pectinata, DC.; Pinus Picea, Lindæus; the Silver Fir.—Mountains of Siberia, Germany, and Switzerland. Yields Strasburgh turpentine.

5. Abies nigra, Michaux; Pinus nigra, Lambert; the Black Spruce Fir.—The concentrated aqueous decoction of the young branches is essence of spruce, used in the preparation of spruce beer.²

Essence of spruce (essentia abietis) is prepared by boiling the young tops of some coniferous plant (in America, those of Abies nigra, or black spruce, are used) in water, and concentrating the decoction by evaporation. "It is a thick liquid, having the colour and consistence of molasses, with a bitterish, acidulous, astrigent taste."³ It is used in the preparation of spruce beer.

Spruce beer (cerevisia abietis) is thus prepared: "Take of Essence of Spruce half a pint; Pimento (bruised), Ginger (bruised), Hops, of each four ounces; Water three gallons. Boil for five or ten minutes; then strain, and add, of Warm Water eleven gallons; Yeast a pint; Molasses six pints. Mix, and allow the mixture to ferment for twenty hours."⁴ It is sometimes taken as an agreeable and wholesome drink in summer. It is diuretic and anti-scorbutic, and is, in consequence, employed in long sea-voyages as a preventive of scurvy.

104. LARIX EUROPEA, DC.—THE COMMON LARCH.

Botany. Gen. Char.—Flowers monocious, Character as in Abies; but the cotyledons are simple, and never lobed. Cones lateral. Leaves, when first expanding, in tufted fascicles, becoming somewhat solitary by the elongation of the new branch (Bot. Gall.).

Hab.—Alps of Italy, Switzerland, Germany, Siberia, &c. Cultivated in woods.

Products.—This species yields larch or Venice turpentine. When the larch forests of Russia take fire, a gum issues forth from the medullary part of the trunks, during combustion, which is called Orenburgh gum (gummi orenburgense). A saccharine matter exudes from the larch, about June, which is called manna of the larch, or manna de Briançon. Lastly, a fungus, called Polyergus officinalis (see ante, p. 92), is nourished on this tree.

⁴ Ibid.
MEDICINAL SUBSTANCES OBTAINED FROM THE PRECEDING CONIFEROUS PLANTS.

The term turpentine (terebinthina) is ordinarily applied to a liquid or soft solid oleo-resinous juice of certain coniferous plants, as well as of the Pistachia Terebinthus, a plant of the order Terebinthaceae, Juss. Indeed, this last-mentioned plant, Pistachia Terebinthus, is probably the true Terebinthus of the ancients (Tiberiunus, Theophr. and Dioscorides). When submitted to distillation, these juices are resolved into volatile oil and resin. The roots, and other hard parts of coniferous trees, yield, by a kind of distillation per descensum, the thick liquid called tar, from which pitch is procured. Hence it will be convenient to speak of the coniferous terebinthines under four heads: 1st, the oleo-resinous juices; 2dly, the volatile oil obtained therefrom by distillation; 3dly, the resinous residuum; 4thly, tar and pitch.

1. Oleo-Resinae Terebinthinae.—Terebinthinate Oleo-Resins.

At first these oleo-resins are liquid, but by age and exposure to the air they become, more or less speedily in the different varieties, solid, partly by the volatilization, and partly by the resinification of the volatile oil. They have a certain general similarity in taste and odour. They soften and become very fluid by heat, readily take fire in the air, and burn with a white flame, and, if the supply of air be limited, with the copious deposition of finely-divided carbon (lamp black). They are almost completely soluble in alcohol and ether; and yield, by distillation, a volatile oil and a resinous residuum. It must not be inferred that the identical volatile oil and resin into which these oleo-resins are resolved by distillation pre-exist in the juices which yield them; for in some cases it is certain they do not, but are products, not euctds, as I have elsewhere shown. Thus balsam of Canada possesses the property of right-handed circular polarization; and, by distillation, yields a volatile oil and a residual resin, both of which enjoy the power of left-handed circular polarization. It is obvious, therefore, that during distillation some molecular change must have been effected in the proximate principles of the balsam. American turpentine, on the other hand, possesses the power of left-handed circular polarization; but, by distillation, yields a volatile oil (oil of turpentine of English commerce) which produces right-handed polarization.

Water acquires a terebinthinate flavour when digested with them; and by the aid of the yolk or the white of an egg, or, still better, by that of vegetable mucilage, forms an emulsion with them.

1. COMMON TURPENTINE (Terebinthina vulgaris).—Under this name we find oleo-resins brought from various parts of the world, obtained from different species of Pinus, and, though agreeing in the main in their properties, possessing certain distinctive characters. At the present time, the London market is almost exclusively supplied from the United States of America, a small quantity only being occasionally imported from Bordeaux.

a. American or White Turpentine, Terebinthina Americana, L. (the Terebenthine de Boston of the French) 1 is procured chiefly from the Pinus palustris, partly, also, from the Pinus Tieda, and perhaps some other species inhabiting the Southern States. In former times, large quantities were collected in New England; but the turpentine trees of that section of the Union are said to be nearly exhausted; and our commerce is almost exclusively supplied from North Carolina and the southeastern parts of Virginia. 2

The method of procuring this turpentine is as follows: A hollow is cut in the tree, a few inches from the ground, and the bark removed for the space of about

2 United States Dispensatory.
15 inches above it. The turpentine runs into these excavations from about March to October; more rapidly, of course, during the warmer months. It is transferred from these hollows into casks. It is imported from New York in casks; those from North Carolina holding 2 cwts., while those from South Carolina contain 2½ cwts. It is yellowish-white, with an aromatic odour, and a warm, pungent, bitterish taste. It is translucent or opake. Its consistence varies, being semifluid, or, in cold weather, that of a soft solid. It contains various impurities (leaves, twigs, chips, &c.). That got from the first tappings is the best, and is called virgin turpentine. Recent American turpentine is said to yield 17 per cent. of essential oil.

This sort of turpentine possesses the property of left-handed circular polarization; but it yields by distillation a volatile oil having right-handed polarization. American turpentine is melted and strained, and in this state it is sometimes called refined turpentine.

Old and concrete American turpentine is sometimes sold for frankincense (thus vel abietis resina).

3. Bordeaux Turpentine is obtained by making incisions in the Pinus Pinaster, Lambert (P. maritima, DC.), and collecting the turpentine in hollows at the foot of the tree. Every month these hollows are emptied, and the oleo-resin conveyed in pails to a reservoir. In this state it is called soft gum (gomme molle). It is purified either by heating it in large boilers, and filtering through straw (térébenthine galipot), or by exposing it in a barrel, the bottom of which is perforated by holes, to the sun; the liquid which drains through is called térébenthine au soleil. The last method yields the best product, since less volatile oil is dissipated by it. The turpentine which flows during the winter is called galipot in Provence, barras in Guienne. It is in the form of semi-opake, solid, dry crusts of a yellowish-white colour, a terebinthinate odour, and a bitter taste.

Bordeaux turpentine is whitish, thickish, and turbid. It has a disagreeable odour, and an acid, bitter, nauseous taste. On standing, it separates into two parts: one thinner, yellow, and almost transparent; another thicker, whitish, and of the consistence of thick honey, having a granular consistence. Bordeaux turpentine readily becomes hard and dry by exposure to the air. It possesses the property of left-handed circular polarization; and yields by distillation an oil which also has left-handed polarization. It enjoys, with balsam of copaiva, the property of solidifying with magnesia, and in this respect is distinguished from Strasburgh turpentine.

Common turpentine has been analyzed by MM. Moringlane, Duponchel, and Bonastre, and by Unverdorben. The last-mentioned chemist found it to consist of two volatile oils (oil of turpentine), pinic acid, a little sylvic acid, a trace of an indifferent resin not soluble in oil of petroleum, and a small quantity of bitter extractive. The quantity of volatile oil varies from 5 to 25 per cent. of the weight of the turpentine. Laurent has discovered in Bordeaux turpentine a resinous acid, pimamic acid, isomeric with pinic acid.

2. LARCH OR VENICE TURPENTINE (Terebinthina veneta; Terebinthina laricea). Obtained from Larix Europaea, DC., by boring the trunks of the trees, and adapting to each hole a wooden gutter, which conveys the juice into a tub or trough, from which it is afterwards withdrawn for filtration.

Through the kindness of Professor Guibourt I have received an authentic sample of larch turpentine. It was collected in the wood of the Bishop of Maurienne, in Savoy, by order of the bishop, and at the urgent solicitation of M. Bonjean, pharmacist, naturalist of Chambery. The same kind of turpentine, collected in Swit-
zerland (Swiss turpentine) is sold in Paris as Strasburg turpentine (Térébenthine de Strasbourg), and was formerly called Venice turpentine. It is a thick and consistent fluid, flowing with difficulty, is sometimes transparent, but more frequently cloudy, has a yellow or greenish-yellow tint, an odour which is peculiar, not very agreeable, weaker than that of either Strasburg or common turpentine, but less disagreeable than the latter, and an acid, very bitter taste. It has little or no tendency to concretse—property known to Pliny, and which distinguishes it from common turpentine.

A factitious substance (terebinthina veneta factitia) is sold by London druggists for Venice turpentine. It is prepared by melting together oil of turpentine and black rosin. A similar preparation is found in the shops of the United States of America, and is probably identical with that imported from America under the name of Venice turpentine.5

Berzelius and Unverdorben6 have submitted Venice turpentine to examination, and with the following results:

**Old Venice Turpentine.**

Fresh Venice Turpentine.

Larch resin yields, according to Berzelius,7 from 18 to 25 per cent. (according to Guibourt only 15 to 24 per cent.) of volatile oil which possesses the power of left-handed circular polarization. Its odour is citron-like, and on this account the oil might be substituted for essence of lemons in the preparation of scouring drops. Its sp. gr. is 0.863.

3. Strasburg Turpentine (Terebinthina argentoratensis; Térébenthine au citron, ou Térébenthine d’Alsace, Guib.)—This is obtained from *Abies Picea.* The peasantry, in the vicinity of the Alps, collect it by puncturing the vesicles adhering to the bark with sharp-pointed hooks, and receiving the juice in a bottle. It is afterwards filtered through a rude kind of bark funnel.

Strasburg turpentine is very fluid, transparent, of a yellowish colour, has a very agreeable odour of citron, and a taste moderately acid and bitter. It consists, according to Caillot, of volatile oil 33.5, resin insoluble in alcohol 6.20, abietin (a crystalizable resin) 10.85, obietic acid (pine and sylvic acids) 46.39, extractive and succinic acid 0.85, loss (principally volatile oil) 2.21.

4. Canadian Turpentine, or Canada Balsam (Terebinthina canadensis; Balsamum canadense), is obtained from *Abies balsamea* in Canada and the State of Maine. Between the bark and the wood of the trunks and branches of these trees are vesicles containing this oleo-resin, which exudes when they are broken, and is received in a bottle. It is imported in casks containing each about one cwt. When fresh it has the consistence of thin honey, but by age gradually solidsifies: it is yellow, transparent, very tenacious, of a peculiar and agreeable terebinthinate odour, and of a slightly bitter, somewhat acid, taste. Like Bordeaux turpentine, it solidifies when mixed with a sixth of its weight of calcined magnesia. It is imperfectly soluble in alcohol.

Canada balsam has been analyzed by Bonastre, who obtained the following

---

1. Guib. MSS.
7. *Drog. et Chim.*
8. Vol. ii.—19
results: volatile oil 18.6, resin easily soluble in alcohol 40.0, subresin difficultly soluble 33.4, fibrous caoutchouc, like subresin, 4.0, acetic acid traces, bitter extractive and salts 4.0.

Balsam of Canada possesses the property of right-handed circular polarization; but both the oil and resin, into which it is resolved by distillation, have left-handed polarization. 1

Canada balsam is used by varnish-makers, by opticians as a cement, and by microscopists as a medium for mounting objects in.

The great value of Canada balsam for optical purposes depends on its transparency and its refractive power, which is nearly equal to that of glass. When used to connect the pieces of an achromatic lens, it prevents the loss of light by reflexion, and excludes moisture and other foreign bodies from the space between the surfaces of the glasses. In Nicol’s prisms (single image prisms of Iceland spar), it serves the important purpose of transmitting the ordinary ray, and of interrupting the passage of the extraordinary one; its index of refraction being intermediate between that of Iceland spar for the ordinary ray and that of the same substance for the extraordinary ray. The following table of indices of refraction serves to illustrate the preceding statements:—

5. COMMON FRANKINCENSE (Abietis resinæ; Thus).—This is the spontaneous exudation of Abies excelsa. I am indebted for an authentic sample of this oleo-resin to Mr. Daniel Hanbury, who collected it, in the autumn of 1849, from the A. excelsa, in Switzerland. It is a soft solid, glistening in places, as if covered with a film of water. Its colour is not uniform: it is whitish, yellowish, pinkish, or pale violet red, and dark in different portions. The pinkish or violet red or peach-blossom hue seems to have been produced by exposure of the resin to the air and light, and in this circumstance resembles the peach-blossom red colour which assafetida acquires under similar circumstances. It is probable, however, that this tint is not permanent. Its odour is not disagreeable, but is somewhat like that of Strasburg turpentine. Guibourt says it is analogous to that of castoreum. The taste is balsamic, and without any bitterness.

When melted in water, and strained through a coarse cloth, it forms Burgundy pitch (pix abietina vel burgundica; poix jaune ou blanche). An authentic sample, prepared by Mr. D. Hanbury from thus collected by himself, is of an opake whitish-yellow colour, somewhat resembling emplastrum plumbi.

The substance sold as common frankincense in the London shops is usually concrete American turpentine; and most of the so-called Burgundy pitch found in commerce is a fictitious article.

Common frankincense or thus has been analyzed by Caillot,2 who obtained the following results: volatile oil 32.00, resin insoluble in alcohol 7.40, abietin (a crystallizable resin) 11.47, abietic acid (? pinie and sylvic acids) 45.37, extractive and succinic acid 1.22, loss (chiefly volatile oil) 2.54.

Physiological Effects.—The effects of terebinthinate substances have been before noticed (see vol. i. p. 254). Locally they operate as irritants. Applied to the skin they cause rubefaction, and sometimes a vesicular eruption. Swallowed they give rise to a sensation of warmth at the stomach, in large doses occasion sickness, and promote the peristaltic movement of the intestines. After their absorption they operate on the general system as stimulants, and excite the vascular system, especially of the abdominal and pelvic viscera. Their influence is principally directed to the secreting organs, more especially to the mucous membranes and the urinary apparatus. They act as diuretics, and communicate a violet odour to the urine. This odour depends on a portion of the oil having undergone a slight change in its nature during its passage through the system. Part of the oil, however, is thrown

---

2 Journ. de Pharm. i. xvi. p. 439.
off unchanged; for Moiroud has observed that, at the same time that the turpentines cause a violet odour, they flow in part with the urine. "I have verified," says he, "this double phenomenon on many horses, to whom turpentine has been given, for some days, in the enormous dose of ten or twelve ounces." But the kidneys are not the only parts engaged in getting rid of the absorbed turpentine. All the secreting organs, but more especially the bronchial surfaces and the skin, are occupied in the same way. By these the oil is exhaled apparently unchanged, or at least with its usual odour. During the circulation of the terebinthinbate particles in the system, they exercise a local influence over the capillaries and secrening vessels, in the vital activity of which they effect a change. In certain morbid conditions, this change is of a most salutary nature. In catarrhal affections of the mucous membranes the secrening vessels become constrained under the use of terebinthinates, and the discharge is, in consequence, checked.

The most important, because by far the most active, constituent of the terebinthinate oleo-resins is volatile oil. Hence their effects are almost identical with those of the latter, and will be noticed hereafter (see p. 1193). Some slight differences, however, are to be noticed. They are less rapidly absorbed, are more permanent in their operation, confine their influence principally to the apparatus of organic life, not affecting, at least to the same extent, the brain, and act less powerfully on the cutaneous system.

We have few data on which to rely in judging of the comparative influence of the different terebinthinates; but as their most active constituent is volatile oil, we may fairly infer that those which possess the greatest liquidity, and which, in consequence, contain the largest quantity of oil, are the most powerful preparations. Venice and Strasbury turpentines stand in this respect pre-eminent. Canada balsam is valuable on account of its purity and agreeable flavour. In activity, purity, and flavour, common turpentine holds the lowest rank.

Uses.—The terebinthinate oleo-resins are, with some exceptions, applicable for the same purposes as the volatile oil. The following are the principal cases in which they are employed:

1. In mucous discharges from the urino-genital organs; as gonorrhoea, gleet, leucorrhoea, and chronic cystirrhoea.

2. In chronic catarrh, both mucous and pititious, occurring in old persons of a lax fibre and lymphatic temperament.

3. In chronic mucous diarrhoea, especially when accompanied with ulceration of the mucous follicles.

4. In colic and other cases of obstinate constipation, Cullen found a turpentine emulsion used as a clyster "one of the most certain laxatives."

5. In chronic rheumatism, especially sciatica and lumbago, the turpentines are occasionally used.

6. As detergents and digestives they have been sometimes applied to indolent and ill-conditioned ulcers.

Administration.—The dose of the terebinthinate oleo-resins is from a scruple to a drachm. They are given in the form of pill, emulsion, or electuary. To communicate to the softer kinds a consistence fit for making pills, liquorice powder may be added to them. Bordeaux turpentine and balsam of Canada, mixed with about one twenty-eighth part of their own weight of calcined magnesia, solidify in about twelve hours; the acid resin combines with the magnesia, and form solid resinate, which absorb the volatile oil. A turpentine emulsion is made with the yolk of egg, or mucilage of gum Arabic, sugar, and some aromatic water. To form an electuary the turpentine is mixed with sugar or honey. An emulsion, containing from half an ounce to an ounce of turpentine, may be used as a clyster, in obstinate constipation, ascarides, &c.

1 Pharmacol.—Vetin. p. 312. 2 Treat. of the Mat. Med.
The terebinthinate oleo-resins yield several officinal substances, and enter into several preparations:

1. **Terebinthina vulgaris** yields Oleum Terebinthina and Resina; and enters into the composition of Emplastrum Galbani, L., and Unguentum Elemi, L.

2. **Terebinthina veneta** is a constituent of Emplastrum Cantharidis compositum, E., and Unguentum Infusum Cantharidis, E.

2. **Oleum Terebinthinae, E. D.—Oil of Turpentine.**

This essential oil is frequently, though erroneously, called spirits or essence of turpentine.

**Preparation.**—It is obtained by submitting to distillation a mixture of American turpentine (which has been melted and strained) and water in due proportions, in the ordinary copper still, with a naked fire. The distilled product is found to consist of oil of turpentine swimming on water; the residue in the still is resin. If no water be employed, a much higher temperature is required to effect the distillation, and danger is thereby incurred of causing empyreuma. Mr. Flockton, a large distiller of turpentine in this metropolis, informs me that the average quantity of oil yielded by American turpentine is from 14 to 16 per cent. He also tells me that Bordeaux turpentine yields an oil having a more disagreeable odour, and a resin of inferior quality.

To deprive it of all traces of resinous and acid matters, oil of turpentine should be redistilled from a solution of potash, and this is actually done, as Mr. Flockton informs me. The British Colleges, however, direct it to be purified by distillation with water only.

The directions of the Edinburgh College for the preparation of Rectified Oil of Turpentine (Oleum Terebinthinae purificatum, E.), are as follows:

Take of Oil of Turpentine Oj; Water Oiv. Distil as long as oil comes over with the water.

The London College gives no directions for the rectification of the oil; but places the rectified oil (oleum e terebintho destillatum, rectificatum, L.).

**Properties.**—Pure oil of turpentine is a colourless, limpid, very inflammable fluid. It has a peculiar, and, to most persons, disagreeable odour, and a hot taste. When pure, it is neutral to test paper. Its sp. gr. is 0.86 at about 70° F. It boils at about 314° F.; the density of its vapour is 4.76 (Dumas). It is very slightly soluble in hydrated alcohol; but 100 parts of alcohol, of sp. gr. 0.840, dissolve 13 or 14 parts of it, and absolute alcohol takes up a still larger proportion. The oil is also soluble in ether. Exposed to the air, it absorbs oxygen, becomes yellowish, and somewhat denser, owing to the formation of resin (pine and syloic acids). This resinification is accompanied with the production of a small quantity of formic acid.

Oil of turpentine enjoys the power of rotating the ray of plane-polarized light; but the direction of rotation is different in the English and French oils—in the former being right-handed, in the latter left-handed.
Plan of the apparatus for showing the circular polarization of oil of turpentine.

a. A ray of common or unpolarized light.
b. A glass reflector, placed at an angle of 56°.45, for effecting the plane-polarization of the light.
c. The reflected plane-polarized ray.
d. The oil of turpentine, which effects the double refraction and rotation of the plane-polarized light.
e. The emergent circularly-polarized light.
f. The analyzer (a double refracting rhomb of calcareous spar), which produces two-coloured images: one caused by ordinary refraction, and called the ordinary image (o); the other by extraordinary refraction, and termed the extraordinary image (x).
g. A lens employed to produce well-defined images.

When the eye is applied to the aperture above or in front of the lens g, two circular disks of coloured light (Fig. 281) are perceived: one (o) the ordinary, the other (x) the extraordinary image. The colours of these images are complementary to each other. By rotating the analyzer (f) on its axis, the extraordinary image (x) revolves around the ordinary image (o); each image undergoing a succession of changes of colour; the sequence of colours being different for the English and French oils of turpentine.

**Sequence of Colours for Oil of Turpentine as Obtained by the Right-Handed Rotation of the Analyzer.**

Moreover, the degree of rotatory power is not uniform.

**English oil of turpentine** (obtained by distillation with water from American turpentine) is remarkable for its comparatively feeble odour. A sample of oil whose sp. gr. was 0.863, had a molecular power of right-handed rotation of 18.5 to 18.7.

**French oil of turpentine** (obtained by distillation from Bordeaux turpentine) enjoys the power of left-handed rotation; the intensity of which, however, is subject to some variation, as the following table shows:

Unrectified oil
First product of the rectification with water
Latter product of the rectification with water
Oil rectified without water
Oil rectified without water preserved 10 years with potash.
VEGETABLES.—NAT. ORD. PINACEÆ.

It is obvious, therefore, that the molecular constitution of oil of turpentine is not constant.

Bouchardat found that the unrectified oil was an imperfect solvent of caoutchouc; and the oil rectified without water a better one. But the same oil distilled from bricks was pyrogenous, had a slight lemon-yellow colour, a sp. gr. of 0.8422, a rotatory power of only 8°.68, and a much increased power of dissolving caoutchouc. Rectified oil of turpentine is sold in the shops under the name of camphene, for burning in lamps. When it has become resinified by exposure to the air, it is unfit for the purposes of illumination, and requires to be rectified from carbonate of potash, or some similarly active substance, to deprive it of resin.

The sweet oil of turpentine or sweet spirits of turpentine—sold in the shops for "painting without smell"—does not appear to differ from the rectified oil of turpentine of English commerce.

The common or unrectified oil of turpentine, sold in the shops under the name of turps, contains resin, and is, in consequence, denser and more viscid than camphene. Its sp. gr. varies from 0.87 to 0.884.

Oil of Turpentine | 1 | 130 | 99.99 |

Hydrates of oil of turpentine.—Four hydrates of oil of turpentine are known. When the commercial oil is exposed to an intense cold, crystals either of the binhydride C_{10}H_{18}, 2HO, or of the hexahydrate C_{10}H_{18}, 6HO, are deposited. The latter forms large prismatic crystals, which, at a temperature of about 217° F., became converted into the quadrhydrate C_{10}H_{18}, 4HO. The monohydrate, C_{10}H_{18}, HO, is a liquid which List calls terpinol.

Hydrochlorate of oil of turpentine; Artificial Camphor.—When hydrochloric acid is passed into oil of turpentine, surrounded by ice, two compounds are obtained—one solid, called solid of Kind's artificial camphor; the other fluid, and termed liquid artificial camphor, terebene, or terebenyl.

Solid artificial camphor, C_{10}H_{18}, HCl, is white, transparent, lighter than water, and has a camphoraceous taste. It is neutral to test paper, fuses at a temperature above the boiling point of water, and is volatileizable usually with the evolution of hydrochloric acid. It burns in the air with a greenish sooty flame; and when the flame is blown out, evolves a vapour which has a terebinthinate odour. Distilled with lime, it yields chloride of calcium, water, and a volatile oil called camphilen, which is isomeric with oil of turpentine, but has no rotatory power in relation to polarized light.

The quantity of solid artificial camphor yielded by oil of turpentine depends on the sort of oil employed. From Thenard's experiments, it would appear that French oil of turpentine yields the largest produce.

Artificial camphor does not produce the lesion of the nervous system which is caused by ordinary camphor. Orfila found that half an ounce of it, dissolved in olive oil, and given to a dog, caused merely a few small ulcers in the mucous membrane of the stomach.

Characteristics of Oil of Turpentine.—As a volatile oil, it is recognized by its combustibility, its burning with a very sooty flame, its almost insolubility in water, its solubility in alcohol and in ether, its volatility, and its evaporating without leaving any greasy stain on paper.

It is sometimes used to adulterate other more costly volatile oils; and it may then be detected by one or more of the following characters: 1st, its remarkable odour; 2dly, its rotatory power in relation to polarized light; 3dly, its being only very slightly soluble in diluted spirit; 4thly, its ready admixture with, and solubility in, the fixed oils; 5thly, its not being able to dissolve in the cold, santaline (the colouring principle of the wood of _Pterocarpus santalinus_), whereas some of the other
Oil of Turpentine:—Physiological Effects.

295

volatile oils (as oil of lavender) do dissolve it; 6thly, by the violent action of both chlorine and iodine on it.

Physiological Effects. a. On Vegetables.—Plants exposed to the vapour of this oil are rapidly destroyed. 1

b. On Animals.—On both vertebrated and invertebrated animals it operates as a poison. Injected into the veins of horses and dogs it excites pneumonia. 2 Two drachms thrown into the veins of a horse caused trembling, reeling, falling, inclination to pass urine and stools, and frequent micturition. Inflammatory fever, with cough, continued to the 8th day; then putrid fever appeared. On the 9th day death took place. The body presented all the signs of putrid fever and pneumonia (Hertwich). Schubarth 3 found that two drachms of the rectified oil, given to a dog, caused tetanus, failure of the pulse and breathing, and death in three minutes. The skin of the horse is very sensible to the influence of oil of turpentine, which produces acute pain. "It is a remarkable circumstance," says Moiroud, 4 "that this pain is not accompanied with any considerable hyperemia. It is quickly produced, but is of short duration." Oil of turpentine is sometimes employed by veterinarians as a blister, but it is inferior to cantharides, and, if frequently applied, is apt to blemish (v. c., to cause the hair of the part to fall off). In doses of three ounces it is a most valuable antispasmodic in the colic of horses. 5 In small doses it acts as a diuretic. Tiedemann and Gmelin 6 detected oil of turpentine in the chyle of a dog and a horse, to whom this agent had been given.

g. On Man.—In small doses (as six or eight drops to 15 j) it creates a sensation of warmth in the stomach and bowels, becomes absorbed, circulates with the blood, and in this way affects the capillary vessels, and is thrown out of the system by the different excretories, on the secering vessels of which it acts in its passage through them. The exhalations of the skin and bronchial membranes acquire a marked terebinthinate odour, while the urine obtains the smell of violets. By its influence on the renal vessels it proves diuretic. By the same kind of local influence on the cutaneous vessels it proves sudorific. It appears to have a constringing effect on the capillary vessels of the mucous membranes, for, under its use, catarrhall affections of, and hemorrhages from, these parts are frequently checked, and often are completely stopped. Its continued use sometimes brings on irritation of the urinary organs, or when this state pre-existed, it is often aggravated by the use of turpentine.

In a medium dose (15 j or 15 j) its effects are not constant. Dr. Ed. Percival 7 saw two drachms given without any unpleasant effect being produced either on the digestive or urinary organs; they acted as an agreeable stomachic, and promoted the catamenia. Mr. Stedman, 8 on the other hand, has seen this dose produce strangury, bloody urine, suppression of this secretion, fever, thirst, and vomiting. These two cases, however, may be regarded as the opposite extremes; and, in general, we may expect, from a medium dose, a feeling of heat in the stomach and bowels, accelerated peristaltic motion, increased frequency of pulse, diaphresis, diuresis, and sometimes irritation of the urinary organs. Occasionally it provokes the catamenia.

In a large or maximum dose (15 iv to 15 j) its effects are not constant. It usually causes a sensation of abdominal heat, sometimes nauseates, and in general operates as a tolerably active purgative, without causing any unpleasant effects. I have administered from one to two fluidounces in a considerable number of cases of tapeworm, and have rarely seen any ill consequences therefrom. "It has been given," says Dr. Duncan, 9 "even to the extent of four ounces in one dose, without any perceptible bad effects, and scarcely more inconvenience than would follow from an equal quantity of gin." Cases are reported, however, in which it has failed to

1 De Candolle, Phys. Veg. p. 1367.
4 Yousart, The Horse, in Library of Useful Knowledge.
7 Edinb. Dispensatory.
produce purging, and in such it has acted most violently on the system, accelerating the pulse, depressing the muscular power, and giving rise to a disordered state of the intellectual functions, which several persons have compared to intoxication. A remarkable and well-detailed instance of this occurred in the person of Dr. Copland, who refers the disorder of the cerebral functions, in his case, to diminished circulation of blood in the brain; while the gastric heat, &c., he ascribes to increased vascular activity in the abdominal region. The oil passed off most rapidly by the skin and lungs (principally by the latter), and the air of the apartment became strongly impregnated with its effluvia. In some cases it causes sleepiness. Purkinje experienced this effect from one drachm of the oil. Dr. Duncan has sometimes seen it produce "a kind of trance, lasting twenty-four hours, without, however, any subsequent bad effect." The same writer adds, "the largest dose I have known given has been three ounces, and without injury." A scarlet eruption is mentioned by Wibmer as being produced in one case by an ounce of the oil.

Uses.—The following are the principal uses of the oil of turpentine:

1. As an anthelmintic. — It is the most effectual remedy for tape-worm we possess. It both causes the death of, and expels the parasite from the body. To adults it should be given in doses of an ounce at least. I have frequently administered an ounce and a half, and sometimes two ounces. Occasionally, as in Dr. Copland's case, it fails to purge, but becoming absorbed, operates most severely on the system, causing disorder of the cerebral functions. It is said to be more apt to act thus in persons of a full and pectoral habit. To prevent these ill consequences, an oleaginous purgative should be either conjoined with it, or given at an interval of four or five hours after it. An excellent and safe method of employing it is to combine it with a castor-oil emulsion. Chaber's empyreumatic oil (described at vol. i. p. 263) used by Bremser against tape-worm, consists principally of oil of turpentine. A very effectual remedy for the small thread-worm (Ascaris vermicularis) is the turpentine enema.

2. In blennorrhoea.—Oil of turpentine sometimes checks or stops profuse chronic discharges from the mucous membranes. It appears to effect this by a topical influence over the capillary and secreting vessels, in its passage through them out of the system. In many cases, it would appear to confine its operation to the production of an increase of toxicity in the vessels which pour out mucus; but in other instances, especially in blennorrhoea of the urinary apparatus, it seems to set up a new kind of irritation in the affected membrane, which supersedes the previously existing disease. Hence its use is not admissible in acute or recent affections of these tissues. In gonorrhoea and gleet I have frequently employed it as a substitute for balsam of copaiba with success. In leucorrhoea it has occasionally proved serviceable. In catarrhus vesicae or cystirrhoea, it now and then acts beneficially; but it requires to be used in small doses and with great caution. In chronic pulmonary catarrh, either mucous or purulent, it is said to have been employed with advantage. In chronic diarrhoea and dysentery it has proved advantageous: in these cases it has a direct local action on the affected part, besides exerting its influence over this in common with other mucous membranes after its absorption.

3. In hemorrhages.—In sanguineous exhalations, called hemorrhages, from the mucous surfaces, oil of turpentine may, under some circumstances, act efficaciously. On the same principle that it checks excessive secretion of mucus in catarrhal conditions of these tissues, so we can readily conceive it may stop the exhalation of blood. But it is only admissible in cases of a passive or atonic character, in the absence of plethora and a phlegmatic diathesis. In purpura haemorrhagica it has been recommended as a purgative, by Dr. Whitlock Nichol, Dr. Magee, and others.

5 Quoted by Wibmer, Wirk. d. Arzn.
I have seen it act injuriously in this disease, while blood-letting has seemed to relieve.

4. In puerperal fever.—The use of the oil of turpentine as a specific in this disease was introduced by Dr. Brenan, of Dublin; and strong testimonies were subsequently borne to its efficacy by several highly respectable practitioners. Dr. Brenan gave one or two tablespoonfuls of the oil, every three or four hours, in cold water, sweetened; and applied flannel soaked in the oil to the abdomen. But the apparent improbability of a stimulant like turpentine curing an inflammatory disease, has prevented many practitioners placing any faith in it, or even giving it a trial. In other instances, the unconquerable aversion which patients have manifested to it, has precluded its repetition. Lastly, it has failed, in the hands of some of our most accurate observers, to produce the good effects which Dr. Brenan and others have ascribed to it, and in some instances has appeared to aggravate the malady. These reasons have been conclusive against its employment, at least in the way advised by Dr. Brenan. But there are two valuable uses which may be made of turpentine, in puerperal fever: it may be given in the form of elysiter, to relieve a tympanitic condition of the intestines, and for this purpose no remedy perhaps is superior to it; secondly, flannel soaked in the hot oil may be applied to the abdomen, to cause rubefaction, as a substitute for a blister, to the employment of which several objections exist.

5. In ordinary fever.—As a powerful stimulant in some forms of low fever, oil of turpentine has been well spoken of by Dr. Holst, Dr. Chapman, Dr. Douglas, and more recently by Dr. Wood. When the skin is dry, the bowels flatulent, and ulceration of the mucous membrane suspected, it often proves most serviceable.

6. In rheumatism.—In chronic rheumatism, oil of turpentine has long been celebrated. Its beneficial influence depends on its stimulant and diaphoretic operation, and is more likely to be evinced in old and debilitated persons. I have found medium doses occasionally succeed when small ones have failed. But for the most part I have not met with that success with it in chronic rheumatism, to induce me to place much confidence in it. In the form of liniment it has often proved serviceable.

7. In sciatica and other neuralgic affections.—Oil of turpentine was proposed as a remedy for sciatica by Drs. Pitcairn and G. Cheyne. Its efficacy was subsequently confirmed by Dr. Home. More recently it has been extensively employed, and with great success, in France, in sciatica as well as in various other neuralgias. But it has proved more successful in those which affect the lower extremities. My own experience does not lead me to speak very favourably of it. In a disease the pathology of which is so imperfectly understood as is that of neuralgia, it is vain to attempt any explanation of the methodus medendi of an occasional remedy for it. I have known oil of turpentine now and then act most beneficially in sciatica, without give rise to any remarkable evacuation by the bowels, skin, or kidneys, so that the relief could not be ascribed to a cathartic, a diaphoretic, or a diuretic operation.

8. In suppression of urine.—I have seen oil of turpentine succeed in reproducing the urinary secretions when other powerful diuretics had failed.

9. In infantile diabetes.—Dr. Dewees has cured three cases of diabetes in infants under fifteen months old "by keeping the bowels freely open, and putting a quantity of spirits of turpentine upon the clothes of the children, so as to keep them in a terebinthine atmosphere."

10. In nephritic diseases.—In some diseases of the kidneys, as ulceration, the use of oil of turpentine has been much extolled. It has proved successful in renal hydatids.

7 Cita. Experimenta.
9 Treatise on the Physical and Moral Treatment of Children.
10 Bayle, op. cit.
11. In dropsy.—Oil of turpentine has occasionally proved serviceable in the chronic forms of this disease. Its efficacy depends, in part, on its derivative operation as a stimulating diuretic; and in part, as I conceive, on its powerful influence over the capillary and secering vessels, by which it exercises a direct power of checking effusion. It is inadmissible, or is contraindicated, in dropsies accompanied with arterial excitement, or with irritation of the stomach or the urinary organs. When the effusion depends on obstruction to the return of venous blood, caused by the pressure of enlarged or indurated viscera, tumours, &c., turpentine can be of no avail. But in the atonic forms of dropsy, especially in leucophaenigmatic subjects, attended with deficient secretion of the skin and kidneys, this oil is calculated to be of benefit. Dr. Copland has used it in the stage of turgescence, or invasion of acute hydrocephalus, as a drastic and derivative.

12. In spasmodic diseases.—Oil of turpentine has been employed successfully in the treatment of epilepsy, by Drs. Latham, Young, Ed. Percival, Lithgow, Copland, and Pritchard. No benefit can be expected from this or any other medicine, when the disease depends on organic lesion within the osseous envelops of the nervous centres. But when the disease is what Dr. Marshall Hall terms centripetal or eccentric (as the convulsion of infants frequently is), that is, takes its origin in parts distant from the cerebro-spinal axis, which becomes affected only through the incident or excitor nerves, we can easily understand that benefit may be obtained by the use of agents like this, which, while it stimulates the abdominal viscera, operates as a cathartic and anthelmintic, and produces a derivative action on the head. A more extended experience of its use in chorea, hysteria, and tetanus, is requisite to enable us to speak with confidence of its efficacy in these diseases, though a few successful cases have been published.

13. In inflammation of the eye.—Mr. Guthrie has employed oil of turpentine in inflammation of the iris and choroid coat, on the plan recommended by Mr. Hugh Carmichael. In some cases, especially those of an arthritic nature, it succeeded admirably, in others it was of little or no service. It was given in doses of a drachm three times a day.

14. In tympanites.—To relieve flatulent distension of the stomach and bowels, and the colic thereby induced, both in infants and adults, oil of turpentine is a most valuable remedy. It should be given in full doses, so as to act as a purgative; or when, from any circumstance, it cannot be exhibited by the mouth, it may be employed in the form of oyster. Dr. Ramsbotham speaks in the highest terms of the efficacy of the oil of turpentine in the acute tympanites of the puerperal state, and thinks that most of the cases of the so-called puerperal fever, which yielded to this oil, were in fact cases of acute tympanites; and in this opinion he is supported by Dr. Marshall Hall.

15. In obstinate constipation.—Dr. Kinglake, in a case of obstinate constipation, with a tympanitic condition of the intestines, found oil of turpentine a successful cathartic, after the ordinary means of treating these cases had been assiduously tried in vain. Dr. Paris also speaks highly of it in obstinate constipation depending on affections of the brain.

16. To assist the passage of biliary calculi.—A mixture of three parts sulphuric ether and two parts oil of turpentine has been recommended as a solvent for biliary calculi. But there is no foundation for the supposition that the relief which may be obtained by the use of this mixture in icterus, and during the passage of a biliary calculus, depends on the dissolution of the latter.

---

8 Pharmacologia.
Oil of Turpentine:—Administration.

17. As an external remedy.—Oil of turpentine is employed externally, as a rubefacient, in numerous diseases, on the principle of counter-irritation, before explained (vol. i. p. 170). Thus in the form of liniment, it is used, either hot or cold, in chronic rheumatism, sprains, sore throat, neuralgic affections of the extremities, &c. In the form of fomentation the hot oil is applied to produce redness of the skin in puerperal peritonitis, as I have already mentioned. As a powerful local stimulant, it was recommended by Dr. Kentish as an application to burns and scalds, his object being to restore the part gradually, not suddenly, to its natural state, as in the treatment of a case of frost-bite. The practice is most successful when the local injury is accompanied with great constitutional depression. I can bear testimony to its efficacy in such cases, having employed it in several most severe and dangerous burns with the happiest results. In that form of gangrene which is not preceded by inflammation, and is called dry or chronic, oil of turpentine may occasionally prove serviceable, especially when the disease affects the toes and feet of old people. There are many other topical uses to which it has been applied; but as they are for the most part obsolete, at least in this country, I omit any further mention of them. They are fully noticed in the works of Voigts and Richter.

Oil of turpentine is the principal ingredient in Whitehead’s Essence of Mustard, which contains also camphor and a portion of the spirits of rosemary. St. John Long’s liniment consisted of oil of turpentine and acetic acid, held in suspension by yolk of egg.

Administration.—When given as a diuretic, and to affect the capillary and secering vessels (in catarrhal affections of the mucous membranes, dropsy, suppression of urine, hemorrhage, &c.) the dose is from six or eight minims to 5 j.; as a general stimulant (in chronic rheumatism, chorea, &c.) or to produce a change in the condition of the intestinal coats (in chronic dysentery), from 5 j. to 5 ij.; as an anthelmintic (in tape-worm) or as a revulsive (in apoplexy, in epilepsy previous to an expected paroxysm, &c.), from 5 iij. to 5 ij. It may be taken floating on some aromatic water, to which some hot aromatic tincture, as tinctura capsici, has been added; or it may be diffused through water by the aid of mucilage or an emulsion; or it may be made into a linctus with honey or some aromatic syrup.

1. ENEMA TEREBINTHINE, L. E. D.; Cluster of Turpentine.—(Oil of Turpentine f 5 j.; the Yolk of one Egg; Decoction of Barley f 3 xix. Rub the oil with the yolk, and add the decoction, L.—The Edinburgh College substitutes plain Water for Barley Water.—The Dublin College orders of Oil of Turpentine f 5 j.; Mucilage of Barley f 5 xvj.)—Used as an anthelmintic in ascarides; as an antispasmodic and purgative in colic, obstinate constipation, and typanities. Dr. Montgomery says, “it is much used in cases of peritoneal inflammation.”

2. LINIMENTUM TEREBINTHINAE, L. D.; Linimentum Terebinthinatum, E.; Turpentine Liniment.—(Soft Soap 5 j.; Camphor 5 j.; Oil of Turpentine f 3 xvj. “Shake them together until they are mixed,” L.—Resinous Ointment 5 iv; Oil of Turpentine f 5 v; Camphor 5 as. Melt the ointment, and gradually mix with it the camphor and oil till a uniform liniment be obtained,” E.—Ointment of White Resin 5 viij; Oil of Turpentine f 5 v, D.)—Introduced by Dr. Kentish as a dressing for burns and scalds. The parts being first bathed with warm oil of turpentine, alcohol, or camphorated spirit, are to be covered with pledgets of lint thickly spread with this liniment. When the peculiar inflammation, excited by the fire, has subsided, milder applications are then to be resorted to. This liniment may also be used in any other cases requiring the employment of a more stimulant application than the ordinary soap liniment.

1 Essay on Burns.

3 Observations on the Dublin Pharmacopœia.
6 Essay on Burns.
3. Resinæ Terebinthinae.—Terebinthinate Resins.

(Quod restat Terebinthinae postquam oleum destillatum est, L.)

Preparation.—This is the residue of the process for obtaining oil of turpentine. It is run, while liquid, into metallic receivers coated with whitening to prevent adhesion, and from these is ladled into wooden moulds or casks. When the distillation is not carried too far, the product contains a little water, and is termed yellow rosin (resina flava). A more continued heat expels the water and produces transparent rosin; and if the process be pushed as far as it can be without producing a complete alteration of properties, the residue acquires a deep colour, and is termed brown or black rosin, or colophonium (resina nigra seu colophonium). If melted rosin be run into cold water contained in shallow tanks, and a supply of cold water be kept up until the rosin has solidified, a pale yellow product is obtained, called Flockton's patent rosin.

Properties.—Rosin is compact, solid, brittle, almost odourless and tasteless, with a smooth, shining fracture, becomes electric by friction, is fusible at a moderate heat, decomposable at a higher temperature, and burning in the air with a yellow smoky flame. It is insoluble in water, but soluble in alcohol, ether, and the volatile oils. With wax and the fixed oils it unites by fusion; with the caustic alkalis it unites to form a resinous soup (the alkaline resinates, principally the pinates). Heated with concentrated sulphuric or nitric acid mutual decomposition takes place.

By distillation, rosin yields rosin oil and tar. Rosin oil is a mixture of four carburets of hydrogen: retinaphte, C₄H₄; retinyl, C₆H₁₂; retinole, C₆H₁₆; and metanaphthaline, C₆H₈. The rosin oil which distils over at from 226½° F. to 302° F. is a mixture of retinaphte and retinyl. It is sometimes used in the arts as a substitute for oil of turpentine. The part which boils at about 464° F. is retinole; it enters into the composition of some printing inks. Mixed with lime, it forms a sort of grease for wheels, machinery, &c. Rosin oil has been used in the preparation of rosin gas.

Yellow rosin is opaque— and yellow, or yellowish-white. Its opacity is owing to water, with which it is incorporated. By continued fusion this is got rid of, and the rosin then becomes transparent (transparent rosin). Brown rosin, or colophony, is more or less brown and transparent.

Composition.—Rosin is a compound or mixture of pinic acid (principally), colophonic acid (variable in quantity), sylvic acid (a small quantity), and traces of an indifferent resin.

Pinic and sylvic acids are isomeric: according to Laurent, their equivalent is expressed by the formula C₆H₄(8O₂)H₂O; and their salts by the formula MO,C₆H₄(8O₂)H₂O.

1. Pinic Acid.—It is soluble in cold alcohol of sp. gr. 0.883. The solution forms a precipitate (pinate of copper) on the addition of an alcoholic solution of acetate of copper. Pinate of magnesium dissolves with difficulty in water.

2. Colophonic Acid (Colopholic Acid).—Formed by the action of heat on pinic acid, and therefore the quantity of it contained in rosin varies according to the heat employed. Rosin owes its brown colour to it. It is distinguished from pinic acid by its greater affinity for saline bases, and its slight solubility in alcohol.

3. Sylvic Acid.—Is distinguished from pinic acid by its insolubility in cold alcohol of sp. gr. 0.883.

4. Indifferent Resin.—Is soluble in cold alcohol, oil of petroleum, and oil of turpentine. It forms with magnesium a compound readily soluble in water.

Physiological Effects.—Not being used internally, its effects when swallowed are scarcely known. It is probable, however, that they are of the same kind as those of common turpentine, though very considerably lighter. In the horse it
acts as a useful diuretic, in doses of five or six drachms. Its local influence is mild. "It may be considered," says Dr. Maton, "as possessing astringency without pungency."  

Use.—Powdered resin has been applied to wounds to check hemorrhage, and is occasionally used for this purpose in veterinary practice. But the principal value of resin is in the formation of plasters and ointments, to which it communicates great adhesiveness and some slightly stimulant properties.

1. Ceratium Resinæ, L. [U. S.]; Unguentum resinorum, E.; Unguentum Resinaræ, D.; Yellow Basilicon or Basilicon Ointment, offic. (Resin, Wax, of each 3xv; Olive Oil Oj. Melt the resin and the wax together with a slow fire; then add the oil, and press the cerate, while hot, through a linen cloth, L.—The Edinburgh College orders of Resin 3xv; Axunje 5viiij; Bees' Wax 5ij. Melt them together with a gentle heat, and then stir the mixture briskly while it cools and concretes. [The U. S. Pharm. directs the same.]—The Dublin College orders of Resin, in coarse powder, 1bss; Yellow Wax 3iv; Prepared Lime 1b.)—A mildly stimulant, digestive, and deterrent application to ulcers which follow burns, or which are of a foul and indolent character, and to blistered surfaces to promote a discharge.

2. Emplastrum Resinæ, L. D. [U. S.]; Emplastrum resinorum, E.—Has been already described at vol. i. p. 715.

Preparation.—True Burgundy pitch is prepared by melting common frankincense (Abietes resina; Thus) in hot water, and straining through a coarse cloth. By this process part of the volatile oil and the impurities are got rid of. The substance sold as Burgundy pitch in the shops is rarely prepared in this way, but is fictitious. Its principal constituent is resin, rendered opake by the incorporation of water, and coloured by palm oil. One maker of it informed me that he prepared it from old and concrect American turpentine. I have a sample of genuine Burgundy pitch prepared by Mr. D. Hanbury from Thus collected by himself in Switzerland (see ante, p. 290). In colour it somewhat resembles emplastrum plumbi. Its odour resembles the Burgundy pitch imported from Hamburgh, and which, when strained, constitutes the best commercial Burgundy pitch. Burgundy Burgundy pitch is of a dark colour, and contains many impurities. It would appear to be melted but unstrained Thus. It yields, when re-melted and strained, a Burgundy pitch which is darker coloured, but which otherwise agrees with the genuine sample prepared by Mr. Hanbury.

Properties.—Genuine Burgundy pitch is hard, brittle when cold, but readily taking the form of the vessel in which it is kept. It softens by the heat of the hand, and strongly adheres to the skin. Its colour is yellowish-white; its odour is not disagreeable; its taste slightly bitter. Fictitious Burgundy pitch is usually of a fuller yellow colour than the genuine, and has a somewhat less agreeable odour.

Composition.—Consists of resin principally and a small quantity of volatile oil.

Physiological Effects.—Its effects are similar to those of the other terebinthine resins. In activity it holds an intermediate station between common turpentine and resin; being considerably less active than the first, and somewhat more so than the last of these substances. Its local action is that of a mild irritant. In some persons it excites a troublesome vesiculo-pustular inflammation.  

Uses.—It is employed as an external agent only, spread on leather, forming the well-known Burgundy pitch plaster (emplastrum pizz burgundici), which is applied to the chest in chronic pulmonary complaints, to the loins in lumbago, to the joints in chronic articular affections, and to other parts to relieve local pains of a rheumatic character. It acts as a counter-irritant or revulsiive.

1 Young, The Horse, in the Library of Useful Knowledge.

3 Raycr, Treatise on Diseases of the Skin, by Dr. Willis, p. 306.
EMPLASTRUM PICTS, L. E.; Plaster of Pitch.—(Burgundy Pitch lbij; Frankincense [This] 1bj; Resin, Wax, of each 3iv; Expressed Oil of Nutmeg 3j; Olive Oil, Water, of each f3j. Add the oils and water to the pitch, resin, and wax, melted together. Lastly, mix them all, and boil down to a proper consistence, L.—The formula of the Edinburgh College is as follows: Burgundy Pitch lbjss, Resin and Bees’ Wax, of each 3j; Oil of Mace 3ss; Olive Oil f3j; Water f3j. Liquefy the pitch, resin, and wax, with a gentle heat; add to the other articles; mix them well together, and boil till the mixture acquires a proper consistence.)—Stimulant and rubefacient; used in the same cases as the simple Burgundy pitch.

[4. Pix Canadensis, U. S.

Canada Pitch; Hemlock Pitch; the prepared concrete juice of the Abies Canadensis, Mich.—As a substitute for Burgundy Pitch, this article is employed in the United States, over which it has the advantage of being in a state of purity. It is the product of the

Abies Canadensis, or Hemlock Spruce, a large tree, attaining a height of seventy or eighty feet, with a circumference of six or nine feet. The leaves are six or eight lines long, very narrow, flat, and downy at the time of their expansion. The cones are a little longer than the leaves, oval, pendulous, and situated at the extremity of the branches.

This species of Abies is solely a native of North America, and belongs to the coldest regions of the continent, beginning to appear about Hudson’s Bay. In the vicinity of Lake St. John and near Quebec, the forests are filled with it, and it is found in all the Northern States. It prefers high situations, and those the most humid and gloomy.

The wood of this tree is of little value; the bark contains a large amount of tannin, and is used in the tanneries where the oak is scarce.

Hemlock resin does not flow from the bark by incision, but is invariably the result of spontaneous exudation from knots or exrescences, the heat of the sun bringing it to the surface; and it is always obtained from old trees or those approaching decay. The proportion of trees from which any resin can be procured is not more than one in a hundred. Mr. Ellis (Journ. of Pharm., vol. ii. p. 20) informs us that the mode of obtaining it is as follows: “Trees are selected upon whose bark the resin is incrusted, which are easily designated by a streak of a dark brown colour on one side of the tree, from near the top to the bottom. These are cut down, and the bark, upon which the resin has hardened, stripped off and thrown into a kettle containing water, with weights placed upon it to prevent its floating. By boiling the water, the resin is melted and rises to the surface, is skimmed off, and thrown into cold water. It is then put into a coarse linen bag and submitted to a second ebullition, treating it as in the former instance, which deprives it of many of its impurities.”

The quantity from good-sized trees is from six to ten pounds, the average from four to five. The colour of it as it exudes is nearly white; it hardens immediately, and changes to yellow, brown, and sometimes nearly black. Hemlock resin is in masses, very brittle. It is a resin in combination with a small quantity of volatile oil. It is heavier than water, sp. gr. 1.034. The odour is peculiar, and unlike turpentine. To purify it, it should be melted and strained. From its adhesiveness and stimulating properties, it affords a plaster which is equal to that made with Burgundy Pitch, if not superior. It may be employed for the same purposes.]

5. Pix liquida and Pix solida.—Tar and Pitch.

1. Pix Liquida.—Vegetable Tar.

(Bitumen liquidum e ligno igne preparatum, L.—Pix liquida, L. E. D.)

History.—This is the πιγγα of Theophrastus,1 the πισσα νηρά (liquid pitch), or 

ωρος of Dioscorides,2 and the pix liquida of Pliny.3
Preparation.—Two kinds of tar are known in commerce; namely, coal tar and wood tar. They are obtained in the destructive distillation—the first of coal, the second of wood.

Of wood tar there are two sorts: one procured in the northern parts of Europe and in America, from the waste of fir timber, and known in commerce as Stockholm tar, Archangel tar, American tar, &c.; the other obtained as a secondary product in the manufacture of pyroligneous acid and gunpowder charcoal. The former is the kind used in medicine. That which is procured from Pinus sylvestris, in the northern parts of Europe, is considered to be much superior to American tar.

The process now followed seems to be identical with that practised by the Macedonians, as described by Theophrastus. It is a kind of distillatio per descensum of the roots and other woody parts of old pines. As now carried on in Bothnia, it is thus described by Dr. Clarke:—"The situation most favourable to the process is in a forest near to a marsh or bog, because the roots of the fir, from which tar is principally extracted, are always most productive in such places. A conical cavity is then made in the ground (generally in the side of a bank or sloping hill); and the roots of the fir, together with logs and billets of the same, being neatly trussed in a stack of the same conical shape, are let into this cavity. The whole is then covered with turf, to prevent the volatile parts from being dissipated, which, by means of a heavy wooden mallet and wooden stamper, worked separately by two men, is beaten down, and rendered as firm as possible about the wood. The stack of billets is then kindled, and a slow combustion of the fir takes place, without flame, as in working charcoal. During this combustion the tar exudes, and a cast-iron pan being at the bottom of the funnel, with a spout which projects through the side of the bank, barrels are placed beneath this spout to collect the fluid as it comes away. As fast as the barrels are filled, they are bunged, and ready for immediate exportation.

Wood-tar is also obtained as a secondary product, in the manufacture of acetic acid, by the dry distillation of wood.

---

1 Hist. Plant. lib. ix. cap. ii. and iii.
3 Travels in Scandinavia, part iii. p. 254; see also Duhamel, Traité des Arbres.
VEGETABLES.—NAT. ORD. PINACEÆ.

Commerce.—Wood-tar is imported into this country chiefly from the northern parts of Europe (Russia, Sweden, Norway, Denmark, and North Germany)—partly from the United States of America. It usually comes in barrels, each holding 31½ gallons; twelve barrels constituting a last. Tar is also produced in this country.

Properties.—It is a dark brown, viscid, semi-liquid substance, which preserves during a long period its softness. It is soluble in alcohol, ether, and the oils both fixed and volatile. Submitted to distillation, it yields an aqueous acid liquor (pyro-
ligneous acid), and a volatile oily matter (oil of tar); the residue in the still is pitch.

Composition.—Wood-tar is a very complex substance. It consists principally of pyretine (pyrogenous or empyreumatic resin), pyrolene (pyrogenous oil), acetic acid, and water.—Reichenbach has obtained from it creasote, paraffin, cupion, picamar, kapnomor, pittacal, and cedriet.—Pyren and chrysén have likewise been found in it.

The tar obtained from coniferous woods contains also colophony and oil of tur-
pentine.

Physiological Effects.—The effects of tar are analogous to those of turpen-
tine, but modified by the presence of acetic acid and the pyrogenous products. Locally it acts as a stimulant; and when applied to chronic skin diseases and in-
olent ulcers, it frequently induces a salutary change in the action of the capillary and secreting vessels, evinced by the improved quality of the secretions, and the rapid healing of the sores. In such cases, it is termed detergent, digestive, or cicatrisant. Swallowed, it acts as a local irritant and stimulant, becomes absorbed, and stimulates the secreting organs, especially the kidneys, on which it operates as a diuretic. Slight states that a sailor swallowed a considerable quantity of liquid tar, which caused vomiting, great lassitude, and violent pain in bowels and kidneys. The urine was red, and, as well as the other evacuations, had the odour of tar. The head and the pulse were unaffected. The vapour of tar, inhaled, acts as a stimulant and irritant to the bronchial membrane, the secretion of which it promotes.

Uses.—Tar is rarely employed internally. It has, however, been administered in chronic bronchial affections, and in obstinate skin diseases.

The inhalation of tar vapour was recommended by Sir Alex. Crichton in phthisis; but at best it proves only a palliative, and it frequently, perhaps generally, fails to act even thus, and in some cases occasions a temporary increase of cough and irrita-
tion. In chronic laryngeal and bronchial affections it has more chance of doing good. Sir A. Crichton's directions for using it in phthisis are as follows: The tar employed should be that used in the cordage of ships; to every pound of which half an ounce of carbonate of potash must be added, in order to neutralize the pyroligneous acid generally found mixed with the tar, the presence of which will necessarily excite coughing. The tar thus prepared is to be placed in a suitable vessel over a lamp, and to be kept slowly boiling in the chamber during the night as well as the day. The vessel, however, ought to be cleansed and replenished every twenty-four hours, otherwise the residuum may be burned and decomposed—a circumstance which will occasion increased cough and oppression on the chest.

Applied externally, tar is used in various forms of obstinate skin diseases, espe-
cially those which affect the scalp, lepra, &c.

Administration.—Internally, tar is administered either in substance, in the form of pills, made up with wheat flour, or of electuary, with sugar; or in the form of tar water. In substance, it may be taken to the extent of several drachms daily.

1. AQUA PICIS LIQUIDÆ; Tar Water.—(Tar Oij; Water Cong. j [wine measure].) Mix, stirring with a stick for a quarter of an hour; then, as soon as the tar subsides, strain the liquor, and keep it in well-stoppered jars.)—Tar water has the colour of

2 Practical Observations on the Treatment and Cure of several varieties of Pulmonary Consumption and on the Effects of the Vapour of boiling Tar in that Disease, 1828.
3 Dr. Forbes, Translation of Lingenel's Treatise on Diseases of the Chest, p. 365.
4 Trouseau and Pidoux, Traité de Thérap. t. i. p. 459.
Madeira wine, and a sharp empyreumatic taste. It reddens lutesmus, but does not effervesce on the addition of a solution of carbonate of potash, though its colour becomes deepened. With a solution of bicarbonate of potash a very slight effervescence takes place. By persulphate of iron, tar water is rendered very dark, or even blackish. The volatile oil contained in tar water is partly held in solution by acetic acid, which, as is well known, dissolves ercasote. It consists of water holding in solution acetic acid, and pyrogenous oil and resin. Notwithstanding the high evulogies passed on it by Bishop Berkeley, 1 tar water is now rarely employed. It is occasionally administered in chronic catarrhal and nephritic complaints, to the extent of one or two pints daily. As a wash in chronic skin diseases, especially those affecting the scalps of children, I have frequently seen it used, and sometimes with apparent benefit.

2. Unguentum Picis Liquide, L. E. D. [U. Z.]; Tar Ointment.—(Tar, Mutton Suet, of each 1b.) Melt them together, and press through a linen cloth. The Edinburgh College takes of Tar 3v, and Beeswax 3ij.; melt the wax with a gentle heat, add the tar, and stir the mixture briskly, while it concretes on cooling. The Dublin College orders of Tar Oss.; Yellow Wax 3iv.)—Its principal use is as an application to ringworm of the scalp and scalled head, in which it sometimes succeeds, but more frequently fails to cure. It is now and then applied to foul ulcers.

3. Oleum Picis Liquide; Oleum Pini rubrum; Oil of Tar.—This is obtained by distillation from tar. It is a reddish, limpid fluid, having the odour of tar. It is a mixture of various volatile constituents of tar. By redistillation it may be rendered colourless, and then becomes very similar to oil of turpentine. It is occasionally used as an application to ringworm of the scalp and scalled head. Swallowed in a large dose it has proved fatal.

2. Pix nigra.—Black Pitch.

(Pix. L.; Bitumen aridum e Pice liquida preparata; Pix arida.)

History.—This is the πίεας κατά (dry pitch) of Dioscorides, which, he says, some call παλίμησας (pitch re-boiled).

Preparation.—The residuum in the still after the distillation of wood-tar is pitch (pix nigra, L.)

Properties.—At ordinary temperatures it is a black solid, having a brilliant fracture. It softens at 90° F. and melts in boiling water. It dissolves in alcohol, and in solutions of the alkalies and of the alkaline carbonates.

Composition.—Pitch is composed of pyrogenous resin and colophony.

Physiological Effects.—Made into pills with flour or any farinaceous substance, pitch may be taken to a great extent, not only without injury, but with advantage to the general health. It affords one of the most effectual means of controlling the languid circulation, and the inert and arid condition of the skin. As a local remedy it possesses great adhesiveness, and when applied to wounds and ulcers acts as a stimulant and digestive.

Uses.—Bateman speaks favourably of the internal use of pitch in ichthyosis. It has been employed also in other obstinate skin diseases. But the principal use of pitch is in the form of ointment, as an application to cutaneous affections of the scalp.

Administration.—Dose from grs. x to 3j., made into pills with flour. The unpleasant pitchy flavour of the pills is materially diminished by keeping them for some time.

Unguentum Picis, L.; Unguentum Picis nigri; Unguentum Basilicum nigrum vel Tetrpharmacum.—(Black Pitch, Wax, Resin, of each 3xj.; Olive Oil Oj.

1 Sibis, a Chain of Phil. Reflex. and Inq. concerning Tar Water, new edit. Lond. 1744.
3 Lib. i. cap. 97.
Melt them together, and press through a linen cloth.)—Stimulant and digestive; used in the obstinate cutaneous eruptions of the scalp.1

Sub-order II. CUPRESSEÆ.

Ovules erect; pollen spheroidal.

105. JUNIPERUS COMMUNIS, Linn.—COMMON JUNIPER.

Sex. Syst. Dioecia, Monadelphia.

(Fructus; et Oleum e fructu destillatum, L.—Cacuminia; Fructus; Oleum, E.—Cacuminia; Baece, D.)

[Juniperus. The fruit of Juniperus Communis, U. S.]

History.—The tree which in our translation of the Bible2 is called the juniper, is supposed to have been a leguminous plant, either broom or furse (genista vel ulex).

Juniperus communis is a native of Greece, and must, therefore, have been known to the ancient Greeks. Sibthorpe3 thinks that it may perhaps be the ἀρχαίος μικρόν of Dioscorides,4 a name which Fraas5 considers to have been applied to Juniperus oxycedrus. The last-mentioned authority is of opinion that the κιδωτός μικρόν of Dioscorides6 is our juniper. The fruit mentioned in the Hippocratic writings under the name of ἀρχαίος, and which was used in some disorders of females, was the produce of a species of Juniperus; perhaps, of the J. phoenicia, which is very common in Greece and the islands of the Archipelago, and whose fruit is yellowish, but has the size, form, and powers of that of the common juniper.

Sp. Char.—Leaves 3 in each whorl, spreading, linear-subulate, keeled, mucronate, longer than the galbulus.

A bushy shrub. Leaves evergreen, numerous, with a broad, flat, shallow channel above, the keel beneath with a slender furrow, pungent, glaucescent on the upper side, dark green beneath. Flowers axillary, sessile, small; the males discharging a copious cloud of yellow pollen; females green, on sealy stalks. Fruit commonly called a berry, but is in reality that kind of cone called by botanists a galbulus, which has fleshy coalescent carpella, whose heads are much enlarged. It requires two seasons to arrive at maturity. The galbulus is black tinged with blue, and is scarcely more than half the length of the leaves.

Loudon7 mentions no less than seven varieties; but some of these are probably distinct species.

Juniperus nana (Smith), Dwarf Alpine Juniper, has a procumbent stem; imbricated, incurved, linear-lanceolate leaves; and fruit nearly as long as the leaves.—Indigenous. On mountains.

---

1 Vide Unguentum Pictis liquidae.
2 Job, xxx. 4; 1 Kings, xix 4.
3 Prod. Fl. Graca.
4 Ibid. cap. 165.
5 Ibid. 105.
Hab.—North of Europe. Indigenous, growing on hills and healthy downs, especially where the soil is chalky. It flowers in May.

Description.—In this country the fruit and tops, and on the continent, the wood, are official.

Juniper berries (baecce juniperi), as the dried fruit of the shops is commonly termed, are about the size of a pea, of a blackish-purple colour, covered by a glaucous bloom. They are marked superiorly with a triradiate groove, indicating the adhesion of the succulent carpeilla; inferiorly with the bracteal scales, which assume a stellate form (see Fig. 283, e and f). They contain three seeds. Their taste is sweetish, with a terebinthinate flavour; their odour is agreeable and balsamic.

Juniper tops (vacumina seu summitilas juniperi) have a bitter terebinthinate flavour and a balsamic odour.

Juniper wood (lignum juniperi) is obtained either from the stem or root; it evolves a balsamic odour in burning, and, by distillation with water, yields volatile oil. On old stumps there is sometimes found a resinous substance (resina juniperi; sandaraca germanica).

SANDARACH OF JUNIPER RESIN.—The resin called sandarach (sandalarae), or gum juniper (gummi juniperi), is imported from Mogadore. It is the produce of Callitris quadrivalvis, Vent. (Thuja articulata, Desf). Though sold by chemists and apothecaries, it is not employed in medicine. It is used in the manufacture of varnishes. Its powder is pounce.

Commerce.—Juniper berries are imported in bags and barrels from Rotterdam, Hamburg, Leghorn, Trieste, and other European ports. In 1838, duty was paid on 5896 cwt.

Composition.—Juniper berries were analyzed in 1822 by Trommsdorff, and in 1851 by Nicolet. Trommsdorff obtained volatile oil 1.0, wax 4.0, resin 10.0, a peculiar species of sugar with acetate and malate of lime 33.8, gum with salts of potash and lime 7.0, ligum 35.0, water 12.9 (=103.7, excess 3.7).

1. Oil of Juniper (see below).
2. Resin.—Is green, according to Trommsdorff. Nicolet obtained it in the crystalized state, and found it to consist of C₆H₄O₁.
3. Wax.—Is brittle. Consists, according to Nicolet, of C₁₅H₄₂O₄.
4. Sugar.—Is crystalizable, and analogous to grape sugar, according to Trommsdorff. But Nicolet describes it as being like molasses.

Physiological Effects.—Juniper berries and tops are analogous in their operation to the terebinthinate substances. Three ounces of the berries act on the larger herbivorous animals as a diuretic. On man, also, these fruits operate on the urinary organs, promoting the secretion of urine, to which they communicate a violet odour. In large doses they occasion irritation of the bladder and heat in the urinary passages. Piso says their continued use causes bloody urine. They promote sweat, relieve flatulency, and provoke the catamenia. Their activity is principally dependent on the volatile oil which they contain, and which, according to Mr. Alexander's experiments, is, in doses of four drops, the most powerful of all the diuretics.

Uses.—Juniper berries or oil are but little used in medicine. They may be employed, either alone or as adjuncts to other diuretic medicines, in dropsical disorders indicating the employment of renal stimuli. Van Swieten speaks favourably of their use in mild cases of ascites and anasarca. In some affections of the urinogenital apparatus juniper may be employed with advantage. Thus in mucous discharges (as gonorrhoea, gleet, leucorrhoea, and cystirrhoea) it may be used under the same regulations that govern the employment of copaiba and the terebinthinates. Hecker praised it in the first stage of gonorrhoea.

Juniper has been advised in some other diseases, but I do not think it necessary to enumerate them.

3. See his Table, at p. 231.
7. Experimental Essays, p. 149, 1768.
Administration.—The dose of the berries is one or two drachms, triturated with sugar. The infusion (prepared with an ounce of the berries and a pint of boiling water) is a more convenient mode of exhibition; the dose is fœiv every four hours.

1. Oleum Juniperi, E. D. [U. S.]; Oleum Juniperi (Anglicum), L.; Oil of Juniper; English Oil of Juniper.—Is obtained by submitting the fruit, tops, or wood, to distillation with water. The full-grown green fruit yields more than the ripe fruit, for, in the act of ripening, a portion of the oil becomes converted into resin. It is limpid, transparent, nearly colourless, and lighter than water, and causes the left-handed rotation of polarized light—in this respect agreeing with French oil of turpentine. It has the odour of the fruit and an aromatic balsamic taste. It dissolves with difficulty in alcohol. According to Blanchet, it consists of two isomeric oils, carburets of hydrogen, C⁹H¹⁶: one colourless, and more volatile; a second coloured, and less volatile. Both, when agitated with a solution of salt, form crystalline hydrates. The more volatile oil almost entirely constitutes the oil obtained from the ripe fruit. It is soluble in alcohol and in hydrochloric acid, with which it forms a liquid artificial camphor. Its density is 0.859.

The oil is, perhaps, the best form for exhibiting juniper. The dose is two to six drops, either in the form of pill or diffused through water by the aid of sugar and mucilage.

Oleum Empyreumaticum Juniperi.—By the dry distillation of the wood of Juniperus oxycedrus there is obtained, in France, a tarry oil called huile de cade (oleum cadum). It is a brownish, inflammable liquid, having a strong empyreumatic and resinous odour, and an acrid caustic taste. It is employed in veterinary medicine; to cure ulcers in horses, and, formerly, to cure the itch in sheep. Oil of tar, which is often substituted for it, is considered to be inferior. It has also been used in the human subject, both externally and internally; in obstinate skin diseases, worms, toothache, &c. Dose, a few drops.

2. Spiritus Juniperi Compositus, L. E.; Compound Spirit of Juniper.—(Oil of Juniper fœiss; Oil of Caraway, Oil of Fennel, of each m._x_ [m._x_, U. S._]; Proof Spirit, Cong. j. Dissolve, L._—Juniper Berries, bruised, b Jennings; Fennel bruised, and Caraway bruised, of each fœiss; Proof Spirit Oви; Water Oіj. Macerate the fruits in the spirit for two days, add the water, and distil off seven pints, E._) This preparation, when sweetened, may be regarded as an official substitute for genuine Hollands and English gin, both of which compounds are flavoured with juniper. It is used as an adjunct to diuretic mixtures. The dose is fœij to fœiv.

106. Juniperus Sabina, Linn.—Common Savin.

Sex. Syst. Dioecia, Monadelphia.
(Caecumen rariss et exsiccatum. Oleum e caecumine distillatum, L._—Tops, E._)
[Sabina, U. S._]

History.—This is the βπάβαν of Dioscorides,¹ the sabina of Pliny.² Each of these writers notices both the cypress-leaved and the tamarisk-leaved varieties of savin.

Sp. Char.—Leaves ovate, convex, densely imbricated, erect, decurrent, opposite; the opposites pyxidiate (Bot. Gall.). A small bushy shrub. Branches closely invested by the very small glandular leaves. Gallulus round, purple, somewhat smaller than that of Juniperus communis.

London³ mentions five varieties. Of these the most interesting are the two following:—

a. J. S. cypressfolia, Aiton.—The Cypress-leaved Savin. La Sabine même. Leaves acute, more spreading, three lines long.

β J. S. tamaricfolia, Aiton.—The Tamarisk-leaved or berry-bearing Savin. La Sabin femelle. Leaves shorter, almost appressed and obtuse.

Another variety, J. S. folis variegatis, has variegated leaves. A fourth, J. S. prostrata, is a low trailing plant. The fifth, J. S. alpina, is procumbent, and more slender than the fourth.

Hab.—Midland and southern parts of Europe, Asiatic Russia. Cultivated in gardens in this country. Flowers in April.

Juniperus Virginiana, Linn., the Red Cedar (the wood of which is used for black-lead pencils) is used in the United States as a substitute for savin.

Description.—The official parts of the plant are the tops (cucumina, summitates), which consist of the young branches with their attached leaves. They have, in the fresh state (cucumina recentia), a strong, peculiar, heavy odour, especially when rubbed; and a nauseous, resinous, bitter taste. The dried tops (cucumina exsiccatia) are yellowish green, and less odorous than the fresh ones.

Composition.—Some experiments on the composition of savin were made by Berlisky. In 1837, an analysis of this plant was made by a young chemist of the name of Gardes. The constituents are volatile oil, resin, gallic acid, chlorophyll, extractive, lignin, and calcareous salts.

Oil of Savin (see p. 311).

Chemical Characteristics.—An aqueous infusion of savin is yellowish, has the odour and bitter taste of the herb, and forms a soluble green compound (gallate of iron) on the addition of sesquichloride of iron, but is unchanged by a solution of gelatin. Oxalate of ammonia causes, in the infusion, a white precipitate (oxalate of lime). Alcohol acquires a green colour when digested with the tops: on the addition of water to the alcoholic tincture some resin is separated. By distillation with water, both the fresh and dried tops (but especially the first) yield volatile oil.

Detection.—Savin is sometimes employed for criminal purposes, and, therefore, occasionally becomes the subject of medico-legal inquiries. Powdered savin in the stomach and bowels might, on account of its green colour, be mistaken for bile; but, when mixed with distilled water, it entirely subsides; and, provided no bile be intermixed, the supernatant liquor will be devoid of a green colour. The powder, when dry, may be detected to be that of savin by the peculiar odour of this herb. The odorous principle (volatile oil) might, if the quantity of powder be sufficient, be separated by submitting this to distillation with water. Moreover, savin powder yields a green colour to alcohol, and its aqueous infusion strikes a green colour with the tincture of the sesquichloride of iron. If the powder be coarse, the microscope may give us important aid in detecting savin. A careful examination of the woody fibres will detect their circular pores (Fig. 284, A B), characteristic of the Gymnosperms (see ante, p. 282); and by the shape of the apex of the leaves (when these can be obtained), savin (Fig. 284, C D) may be detected from another poisonous gymnospermous plant (Fig. 284, E), namely, the Yew (Taxus baccata).

Fig. 284.

A. B. Woody fibres (magnified) of Savin; showing a, the pores.
C D. Magnified extremity of the leaf of Savin, showing the subulate linear leaves.
E. Magnified extremity of the leaf of Yew (Taxus baccata), showing the linear acute leaves.

1 Trommsdorff's Journ. viii. 1, 94. 2 Journ. de Chim. Méd. t. iii. p. 331, 9de Sér. 3 See an interesting report of a case of poisoning by savin, in which the above characters were successfully used of to detect the poison, by Dr. A. Taylor and Mr. Charles Johnson, in the Lond. Med. Gaz. for Aug. 8, 1845, p. 916.
Physiological Effects.  

a. On Animals.—Savin acts on animals as an acrid poison. Orfila\(^1\) applied two drachms of the powder to an incised wound in the leg of a dog; inflammation and infiltration of the limb took place, and death occurred in about thirty-six hours. Four drachms introduced into the stomach of a dog, and the esophagus tied, caused death in thirteen hours; the stomach was bright red, and the rectum a little inflamed. Orfila infers that its effects depend principally on its absorption and its action on the nervous system, the rectum, and the stomach. A drachm of oil of savin was given by Hillefeld\(^2\) to a cat. It caused a flow of saliva, anxiety, frequent discharge of urine, dulness, trembling, and, in an hour and a quarter, bloody urine. The animal having been strangled, the bladder was found contracted, with some coagulated blood contained in its cavity.

b. On Man.—Oil of savin, the active principle of the herb, is a powerful local irritant. When applied to the skin, it acts as a rubefacient and vesicant. On wounds and ulcers its operation is that of an acrid (not chemical) caustic. Swallowed in large doses, it occasions vomiting, purging, and other symptoms of gastro-intestinal inflammation. In its operation on the system generally, it is powerfully stimulant. "Savin," says Sundelin,\(^3\) "operates not merely as irritants generally do, as a stimulant to the arterial system, but it also eminently heightens the vitality of the venous system, the circulation in which it quickens. It next powerfully stimulates the absorbing vessels and glands, the serous, the fibrous, and the mucous membranes, and the skin. It operates as a specific excitant and irritant on the kidneys, and yet more obviously on the uterus. The increased secretion of bile and the augmented volume of the liver, both of which conditions have sometimes been observed after the copious and long continued use of savin, appear to be connected with its action on the venous system." Mohrenheim\(^4\) mentions the case of a woman, 30 years of age, who swallowed an infusion of savin to occasion abortion. Violent and incessant vomiting was induced. After some days she experienced excruciating pains, which were followed by abortion, dreadful hemorrhage from the uterus, and death. On examination, the gall-bladder was found ruptured, the bile effused in the abdomen, and the intestines inflamed. The popular notion of its tendency to cause abortion leads, on many occasions, to the improper use of savin; and the above is not a solitary instance of the fatal consequences thereof. A fatal case of its use as an emmenagogue is recorded by Dr. Dewees.\(^5\) That it may frequently fail to provoke premature labour is shown by the case, related by Fodéré,\(^6\) of a woman who, in order to produce abortion, took every morning, for twenty days, one hundred draps of this oil, and yet went her full time and brought forth a living child. It ought to be well known that, in those cases in which it may succeed in causing miscarriage, it can only do so at the risk of the woman's life. Vogt\(^7\) says that it has a tendency to induce an apoplectic state in the fetus. The emmenagogue power of savin is fully established. Perhaps the observations of Home\(^8\) are the most satisfactory of any on this subject, confirmed as they are by the reports of many other accurate observers.

Uses.—Savin is not much used internally; but, in cases of amenorrhœa and chlorosis depending on or accompanied by a torpid condition or deficient action of the uterine vessels, it may be given as a powerful uterine stimulant. In such cases it proves a most efficient remedy. According to my own observation, it is the most certain and powerful emmenagogue of the whole materia media. My experience of it, therefore, confirms the statements of Home.\(^9\) Though I have employed it in numerous cases, I never saw any ill effects result from its administration. Of course its use is contraindicated where irritation of the uterus, or indeed of any of the pelvic viscera, exists.

\(^8\) Clinical Experiments, p. 419.  
\(^9\) Icid.
In chronic rheumatism, with a languid circulation in the extreme vessels, Chap-
man1 speaks in very high terms of it. It has been used as an anthelmintic.

As a topical agent, savin is frequently employed, mostly in the form of the cerate, to make perpetual blisters. Equal parts of savin and verdigris, in powder, form one of the most efficacious applications for the removal of venereal warts. The powder, an infusion, or the expressed juice of the plant, is occasionally applied to warts, to old and indolent ulcers, and in cases of psora and tinea.

ADMINISTRATION.—By drying, savin loses part of its volatile oil, and hence the powder is not the best preparation of it. It is, however, sometimes given in doses of from five to fifteen grains. A decoction and extract are also objectionable preparations, on account of the heat employed in making them. An infusion may be prepared by digesting 3 j of the fresh herb in 1/2 vij of boiling water: the dose is one or two tablespoonsfuls. The oil is by far the most convenient and certain preparation of savin, and is the only one which I employ. A conserve of the fresh leaves is sometimes used.

1. CLEUM SABINE, E. D. [U. S.]; Oil of Savin.—This is obtained by submitting the fresh tops to distillation with water. It is a limpid, almost colourless liquid, having the unpleasant odour of the plant, and a bitter acrid taste. Its sp. gr. is 0.915. Its composition is analogous to that of oil of turpentine, being C10H16. It agrees with English oil of turpentine in its power of effecting the right-handed rotation of plane polarized light. Winckler2 states that he dissolved one ounce of savin oil in the same quantity of concentrated sulphuric acid, and then distilled it from milk of lime (to remove the sulphurous acid), and obtained two draehms of an oil which was undistinguished from the volatile oil of thyme. The dose of oil of savin, as an emmenagogue, is from two to six drops, diffused in a mucilaginous or oleaginous mixture.

2. Unguentum Sabine, L. D.; Savin Ointment, E. [U. S.]; Ceratum Sabine.—(Fresh Savin, bruised, lbs; White Wax ½ lb; Jard lb j. Mix the savin in the last and wax melted together, then press through a linen cloth. The Edinburgh College orders of Fresh Savin two parts; Beeswax one part; Axunge four parts. Melt the wax and axunge together, add the savin and boil them together till the leaves are friable; then strain. The Dublin College orders Savin Tops, dried and in fine powder, ½ j; Ointment of White Wax ½ vij. Mix the powder intimately with the ointment by trituration. [The U. S. Pharm. directs Savin, in powder, ½ j; Resin Cerate lb j. Mix the savin with the cerate previously melted.]—The boiling of this ointment is considered objectionable on account of the loss of a portion of the oil. The colour of this cerate should be fine green, and its odour that of the plant; the former property depends on chlorophyll, and the latter on the oil of savin. Savin cerate is used as a dressing to blistered surfaces, to produce what is termed a perpetual blister. It is preferred to the ceratum cantharidis as being less acrid, and not liable to cause strangury. It is sometimes applied to seton tapes, to increase the discharge from setons.

ANTIDOTES.—In a case of poisoning by savin herb or its oil, the first indication is to remove the poison from the stomach and bowels. Opiates and demulcent drinks should then be given. The warm bath may be advantageously employed. Bloodletting should be resorted to if the inflammatory symptoms indicate, and the condition of the system permit it.

ORDER XXIII. TAXACEÆ, Lindl.—TAXADS.

Characters.—Naked-seeded exogens, with repeatedly branched, continuous stems, simple leaves often fork-veined, solitary female flowers, 2-celled anthers opening longitudinally, membrane

1 Elem. of Therap.
2 Buchner's Repertorium, 2ter Reihe, Bd. xii. S. 330, 1846.
next the nucleus of the ovule inclosed. seed usually supported or surrounded by a succulent imperfect cup-shaped pericarp, endosperm straightened, dicotyledonous, and albumen fleshy.

**Properties.**—The Taxaceae agree with the Pinaceae in the resinous quality of their juices, but abound more in bitter astringent, and some of them in narcotic acid principles.

### 107. Taxus baccata, Linn.—Common Yew.

*Sex. Syst. Diccia, Monadelphia.*

(JoHn et semina.)

*Taxus,* baccata, Linn., † by some called *Sinelea,* by the Romans termed *Tafic,* Dioscorides, lib. iv. cap. 80.—*Taxus,* Pini, lib xvi. cap. 20 et 33; and lib. xxiv. cap. 72.—A tree often attaining a considerable bulk. Leaves scattered, nearly sessile, 2-ranked, crowded, linear, acute, entire, very slightly revolute, about 1 inch long, dark green, smooth and shining above, paler with a prominent midrib beneath, terminating in a small harmless point. Flowers axillary sessile. Fruit drooping, consisting of a succulent, sweet, internally glutinous, scarlet cup, inclosing an oval, brown, nuciform seed, unconnected with the fleshy part.—In 1828, Peretti analyzed yew (the leaves?), and obtained a bitter volatile oil, a bitter non-crystallizable substance, a yellow colouring matter, resin, tannin, gallic acid, chlorophyll, mucilage, sugar, and mateate of lime. In 1818, Chevalier and Lassaigne examined the pulp cup of the fruit, and found in it a non-crystallizable fermentable sugar, gum, malic and phosphoric acids, and a carmine-red fatty matter. In 1843, Martin analyzed the seeds, and obtained from them a volatile oil having a terpenolunahote, fixed oil, a green very bitter resin, sugar, albumen (in small quantity), sulphate of lime, and vegetable fibre.

The poisonous properties of yew were known to the ancient Greeks and Romans, and have been fully established by modern experience, although some few writers have expressed doubts concerning them. Percival states that three children were poisoned by the fresh leaves. Dr. Mollan has mentioned the case of a lunatic who died in 14 hours after taking yew-leaves: the symptoms were giddiness, sudden prostration of strength, vomiting, coldness of the surface, spasms, and irregular action of the heart. Mr. Hurt has reported an interesting case of a child, three years and a half old, who died in less than four hours after eating the fruit: the symptoms were vomiting, convulsions, purple lips, and dilated pupil. Considered both in a toxicological and therapeutic point of view, the yew appears to hold an intermediate position between savin and foxglove. To savin it is allied by its botanical affinities and chemical composition, but also by its acrid, evacuant, diuretic, and emmenagogue properties. But, on the other hand, its relation to the neurotics, especially to sedatives (see vol. i., p. 258), is marked by the giddiness, irregular and depressed action of the heart, convulsions, and insensibility which it produces. It is said that, when used for medicinal purposes, it is unlike digitalis, in not being apt to accumulate in the system. As a poison it belongs to the class of acro-narcotics; as a medicine it is used as a sedative, anti-spasmodic, emmenagogue, lithic, and resolvent. As a sedative it has been proposed by Rampinelli and Martin to be used as a substitute for, and under the same indications as, digitalis. As an emmenagogue it has been given in cases similar to those for which savin is sometimes administered. Dr. A. Taylor says that "infusion of yew-leaves, which is popularly called yew-tree tea, is sometimes used for the purpose of procuring abortion by ignorant midwives." As a lithic it has been employed in calculous complaints; as an anti-spasmodic in epilepsy and convulsions; as a resolvent in hepatic and gouty complaints. In pulmonary and vesical catarrh it has likewise been used. The powder of the leaves or seeds is given in doses of from half a grain to two or three grains. The extract of the leaves (extractum taxii, Cod. Hamb.), prepared by evaporating the expressed juice of the leaves, is administered in doses of one or two grains, and gradually increased. The alcoholic and ethereal extract of the seeds is employed in doses of from °f to °f of a grain. In cases of poisoning by yew, the first indication is to expel the poison from the stomach by the means already pointed out (see vol. i. p. 201). The sedative and narcotic effects are to be counteracted by stimulants such as ammonium (see the treatment for poisoning by foxglove).

### Sub-class II. Angiospermae.—Angiosperms.

**Exogens, Lindl.**

**Characters**—Ovules inclosed in an ovary, and fertilized by the application of the pollen to the stigma.

1 Journ de Pharm. t. xiv. p. 537, 1828.
2 Ibid. t. iv. p. 538, 1818.

4 Essays, Med. Phil. and Exper. vol. iii. p. 257.
5 Dublin Hospital Gazette, May 15, 1842, p. 109.
6 Lancet, Dec. 10, 1836.
7 On Poisons, p. 790.
In accordance with the classification followed by De Candolle, the natural orders of this sub-class will be arranged in the four following subdivisions: 1st, Monochlamydeae; 2dly, Corolliflora; 3dly, Calyciflora; and 4thly, Thalamiflora.

SUBDIVISION I. MONOCHLAMYDEAE, De Cand.

Apetala. Endlicher.

Flowers frequently unisexual. Perianth absent, rudimentary or simple, calyccine or coloured, free or connate with the ovary.

ORDER XXIV. LIQUIDAMBARACEAE, Richard.—LIQUIDAMBARS.

Balsamiflora, Blume, Endl.—Altingiaceae et olim Balsamaceae, Lindley.

Characters.—Tall trees, with amantaceous unisexual flowers; a 2 celled, 2 lobed, many-seeded capsule; and winged seeds, with the embryo inverted in fleshy albumen.

Properties.—Balsamic, fragrant.

108. Liquidambar, Linn. *

Altingia, Noronha. *

As this is the only genus of the order, its characters are necessarily those of the latter. It consists of a very small number of species, of which none probably are officinal. But, as their balsamic products have been confounded with storax and balsam of Peru (two official substances), a short notice of them is requisite.

1. L. Styraciflua. Linn; Sweet Gum; White Gum.—A native of the United States and Mexico, attaining, in the southern districts, an immense size. In Louisiana and Mexico there is obtained, by making incisions into the stem, a fluid balsamic juice called liquidambar or copalum balsam. In this fluid state it constitutes the liquid liquidambar, or oil of liquidambar of Guibourt. It is transparent, amber-yellow, has the consistence of a thick oil, a balsamic colour, and an aromatic, acrid, bitter taste. By time it concretizes, and becomes darker coloured. The soft solid called by Guibourt soft or white liquidambar, is perhaps a mixture of the opake deposit of the fluid balsam, and of the latter rendered concrete by keeping. It is a soft, almost opake solid, very similar in appearance to concrete turpentine. Its odour is similar to, though weaker than, the liquid balsam. Its taste is balsamic and sweetish. Bonastre analyzed a very fluid sample, recently received from America, and found it to consist of—volatile oil, 7.0; semi-concrete matter, 11.1; benzoic acid, 1.0; crystalline matter soluble in water and alcohol, 5.3; yellow colouring matter, 2.05; oleo-resin, 49.0; styrarin, 24.0; loss, 0.55. The volatile oil consists, according to Henry, of C_6H_7. Styracin is a fusible, crystalline substance, soluble in boiling alcohol, and composed, according to Henry, of C_6H_8O_3. The proportion of benzoic (cinnamic?) acid is increased by time. Mr. Hodgson obtained from a sample which he examined 4.2 per cent.

Liquidambar has been confounded with both white balsam of Peru and liquid storax. The liquidambar which I have received from M. Guibourt is quite different from a genuine sample of the white balsam of Peru received by me from Guatemala, and it is equally different from the liquid storax of the shops. And Dr. Wood observes that some of the genuine juice of liquidambar styraciflua brought from New Orleans, which he examined, had an odour entirely distinct from that of liquid storax.

A thick, dark-coloured, opake, impure substance is obtained from the young branches of this species by boiling them in water and skimming off the fluid balsam which rises to the surface. This also has been confounded with liquid storax, but none of it comes to this country.

The effects and uses of liquidambar are similar to those of storax and other balsamic substances. The dose of it is from ten to twenty grains.

2. L. Altinsecta, Blume; Altinsecta excelsa, Noronha.—A native of Java, where it is called Rasana-la (Rasamulla or Rosa-mallus, Auct.) It yields a fragrant balsam, which by some writers has been regarded as the liquid storax of the shops. But the latter substance comes to England by way of Trieste, and, according to Landerer, is the produce of Stryx officinalis, and as such I shall describe it hereafter (see Stryx officinalis). Petiver says that the Rosa-mallus grows in Cobross, an island at the upper end of the Red Sea, near Cadess, which is three days' * Journ. de Pharm. t. xvi. p. 339. 1831.
* Journal of the Philadelphia College of Pharmacy, vi. 190.
* Pharmaceutisches Central-Blatt fur 1840, p. 11.
* United States Dispensatory.
* Phil. Trans. vol. xxvi. p. 44.
journey from Suez. Its bark is removed annually, and boiled in salt water until it comes to a consistence like birdlime; it is then separated, put in barrels (each holding 420 lbs.), and sent to Mocha, by way of Jaffa. The Arabs and Turks call it Cotter Mija.

Dr. Marquart 2 analyzed some of the genuine resin of L. Albingii, and, by distillation with carbonate of soda, obtained a volatile oil resembling styrol, and a substance resembling sarsacin, but which had a different composition.

3. L. orientale. Miller; L. imberbe, Aiton; Platamn orientalis, Pocock.—This tree grows in Cyprus, where it is called Xylon Effendi (the wood of our Lord). By incisions made in the bark, it yields a kind of white turpentine, and a very fragrant oil. Dr. Lindley thinks it is probable that the liquid stora of the shops is collected from this tree; but I do not agree with him in this opinion.

ORDER XXV. SALICACEÆ, Lindl.—WILLOWWORTS.

SALICINÆ, Richard.

CHARACTERS.—Flowers unisexual, amentaceous. Stamens distinct or monadelphous; anthers 2-celled. Ovary superior, 1-celled; ovules numerous, erect, at the base of the cell, or adhering to the lower part of the sides; style 1 or 0, stigmas 2 or 4. Fruit coriaceous, 1-celled, 2-valved, many-seeded. Seeds either adhering to the lower part of the axis of each valve, or to the base of the cell; comose; albumen 0; embryo erect; radicle inferior. Trees or shrubs. Leaves alternate, simple, with deliquescent primary veins, and frequently with glands; stipules deciduous or persistent (Lindley).

PROPERTIES.—The barks of the species of this order are astringent and tonic; the astringency being due to tannic acid, the tonic property to salicine or some other bitter principle. An oleoresinous or balsamic substance, of a stimulant nature, is secreted by the buds of some of the species.

109. SALIX, Linn.—WILLOW.

Sex. Syst. Ducein, Diandria.
(Cortex e speciebus salcis diversa; cortex salicis, offic.)

HISTORY.—Dioscorides 3 speaks of the astringent qualities of the iria, or willow (Salix alba?), which was employed in medicine by the ancients. For a long series of years it fell into disuse, but was again brought into notice in 1763, by the Rev. Mr. Stone, 4 who published a paper on the efficacy of the bark of Salix alba, as a remedy for agues. The broad-leaved willow bark (Salix Caprea) was subsequently introduced into practice by Mr. James, 5 whose observations on its efficacy were afterwards confirmed by Mr. White 6 and Mr. G. Wilkinson. 7

BOTANY. Gen. Char.—Flowers dioecious, or rarely monoecious, amentaceous; scales imbricated; a gland surrounding the stamens or ovary. MALES: Stamens 2 to 5, usually 2, sometimes the 2 united into 1, and then the anther is 4-celled. FEMALES: Seeds comose; the radicle inferior (Bot. Gall.).

Species.—Sir J. E. Smith 8 mentions sixty-four indigenous species of Salix; but pharmacological and botanical writers are not agreed as to which species possesses the most medicinal power. The best practical rule to follow is this: Select those whose barks possess great bitterness, combined with astringency. The following are those which are in the greatest repute:—

1. SALIX RUSSELLIANA, Smith; the Bedford Willow.—Leaves lanceolate, tapering at each end, serrated throughout, very smooth. Footstalks glandular or leafy. Germin tapering, stalked, longer than the scales. Style as long as the stigmas (Smith).—A tree. In marshy woods, wet meadows, &c., in various parts of Britain. Flowers in April and May. Its bark abounds in tannic acid. On account of its astringency, Sir J. E. Smith regards it as the most valuable officinal

7 Engl. Flora, iv.
species; and he observes, that if it has occasionally disappointed medical practitioners, they probably chanced in such cases to give the S. fragilis.

2. **Salix alba**, Linn.; the Common White Willow.—Leaves elliptic-lanceolate, pointed, serrated, silky on both sides; the lowest serratures glandular. Stamens hairy. Germen smooth, almost sessile. Stigmas deeply cloven. Scales rounded (Smith).—A tall tree. River-sides, moist woods, &c., in various parts of Britain. Flowers in May. Its bark, called cortex salignum, or cortex anglicanum of some writers, is astringent, but less so than that of the preceding species.

4. **Salix fragilis**, Linn.; the Crack Willow.—Leaves ovate-lanceolate, pointed, serrated throughout, very smooth. Footstalks glandular. Germen ovate, abrupt, nearly sessile, smooth. Scales oblong, about equal to the stamens and pistils. Stigmas cloven, longer than the style (Smith).—A tree. Indigenous; about the banks of rivers. Flowers in April and May.

5. **Salix pentandra**, Linn.; **Sweet Bay-Leaved Willow**.—This species is official in the Prussian Pharmacopoeia, and is preferred by Nees von Esenbeck to all other species. Its bark is the *cortex salicis laureae* of some pharmacologists.

6. **Salix purpurea**, Linn.; **Bitter Purple Willow**.—This species deserves notice on account of the intense bitterness of its bark.

**Description.**—Willow bark (*cortex salicis*) varies, in its appearance and qualities, according to the species and the age of the tree from which it is procured. In the dried state it is usually quilled and odourless. It should have a bitter and astringent taste.

**Composition.**—The bark of *Salix alba* was analyzed by MM. Pelletier and Caventon, 1 who obtained the following results: Bitter yellow colouring matter, green fatty matter similar to that found in cinchona, tannin, resinous extract, gum, wax, woody fibre, and a magnesian salt containing an organic acid.

These celebrated chemists failed to isolate salicine, which must have been contained in their bitter yellow colouring matter, either mixed or combined with some other matter. Their resinous extract is probably identical with what Braconnot calls corticin.

1. **Tannic Acid.**—This is the astringent principle of willow bark. Sir H. Davy 2 gives the following as the quantities of tannin [impure tannic acid] in the bark of two willows:

<table>
<thead>
<tr>
<th></th>
<th>lbs. of tannin.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Leicestershire</td>
<td>31</td>
</tr>
<tr>
<td>Common willow</td>
<td>11</td>
</tr>
</tbody>
</table>

2. **Salicine.**—See p. 316.

**Chemical Characteristics.**—A decoction of the bark, made with distilled water, is coloured dark green (tannate of iron) by sesquichloride of iron; but, made with spring water, dark purple. Solution of gelatin produces a precipitate (tannate of gelatin) in the decoction, but tincture of nutgalls causes no turbidity. A strong decoction of willow bark, containing much salicine, is reddened by concentrated sulphuric acid.

**Physiological Effects.**—Willow bark possesses both bitterness and astringency. It belongs, therefore, to the *astringent bitters*, whose effects have been already noticed (see vol. i., p. 244). It is less apt to disturb the stomach than cinchona, but its tonic and febrifuge powers are less than the latter. Vogt 3 ascribes to it balsamic properties.

---

USES.—It has been employed as an indigenous substitute for cinchona. The indications for its use, therefore, are the same as those for the latter. It is given in intermitents, dyspeptic complaints accompanied with, or dependent on, a debilitated condition of the digestive organs, passive hemorrhages, chronic mucous discharges, in the stage of convalescence after fever, and as an anthelmintic. As a local astringent, the powder or infusion is sometimes employed, but there are many more efficient remedies of this kind.

ADMINISTRATION.—The dose of the powder is 5ss to 5j. The infusion or decoction (prepared with 5j of the bark and 0j of water) may be given in doses of from 15j to 3jii.

SALICINUM; Salicino.—Obtained in a more or less impure state by Brugnatelli, Fontana,1 in 1825, and Buchner2 in 1828, and in a pure state by Leroux3 in 1829. Has been found in about fourteen species of Salix and eight species of Populus.4 It has been detected in the bark, leaves, and flowers. Herberger obtained 250 grains, Merck 251 grains, from 16 ounces of the bark and young twigs of Salix Æliz; Erdmann, however, procured, by another process, 300 grains from the bark of Salix pentandra.5 Merck’s process for obtaining it, as stated by Liebig,6 is as follows:—

"Dried or fresh willow bark is cut small, and exhausted by repeated boiling with water. The decoctions are concentrated, and while boiling treated with litharge till the liquor appears nearly colourless. The dissolved oxide of lead is removed, first by sulphuric acid, afterwards by sulphuret of baryum, and, after the separation of sulphuret of lead, evaporated, when salicine crystallizes; and is purified by repeated solution and crystallization (Merck). From willow bark, which is fresh and rich in salicine, it may be obtained by cautious evaporation of the cold aqueous infusion (Merck). The oxide of lead removes from the solution gum, tannin, and extractive matter, which would impede the crystallization of the salicine. It also combines with the salicine, forming a kind of salt which is decomposed by the sulphuric acid and sulphuret of baryum. If the latter be carefully added, neither sulphuric acid nor baryta remain in the solution; and the sulphuret of lead, which separates, acts as a decolorizing agent."

Salicine crystallizes in silky needles and laminae. It is white, very bitter, in-odorous, neutral to vegetable colours, fusible at 230° F., and combustible at a higher temperature. It rotates to the left a ray of plane polarized light. It is much more soluble in boiling than in cold water, 100 parts of which dissolve only 5.6 parts of salicine. It is also soluble in alcohol, but not so in ether or the volatile oils. It is not precipitated by any agent. Oil of vitriol colours it blood-red.7 By this test the presence of salicine is detected in its solutions, and in decoctions of willow and poplar barks. Chromic acid (or a mixture of bichromate of potash and sulphuric acid) converts salicine ($C_6H_5O_4$) into hydruret of salicyle (also called salicylous acid), $C_6H_5O_4\cdot H$ (oil of meadow-sweet) carbonic acid and formic acid. Hence this acid may be employed as a test for salicine. For this purpose 8 parts of salicine, 3 of bichromate of potash, and 24 of water, are to be dissolved in water, and to the solution 4½ parts of oil of vitriol diluted with 12 parts of water are to be added. On the application of heat, the well-known odour of the flowers of meadow-sweet (Spiraea ulmaria) is evolved. If diluted hydrochloric or sulphuric acid be boiled with a solution of salicine, the fluid becomes suddenly turbid, and deposits a precipitate of saliretine, glucose being at the same time formed.

\[
\begin{align*}
C_6H_5O_4 + 4H_2O & = C_6H_5O_4\cdot H + C_6H_4O_4 \\

Salicene possesses tonic properties analogous to disulphate of quina, than which it is less liable to irritate the stomach. In its passage through the system salicene undergoes oxidation, and is converted into hydruret of salicine, which is found in the urine. Its presence is detected by a persalt of iron, which strikes an intense violet colour with urine containing it. It is employed in dyspepsia, intermittent, and other diseases for which cinchona and disulphate of quina are usually exhibited. In the event of the latter becoming scarce, salicene would prove an exceedingly valuable substitute. The dose of it is from 10 to 30 grains. It may be given in powder mixed with sugar or dissolved in some aromatic water. Its quickest action in intermittent is said to be obtained when it is given in powder.

**ORDER XXVI. CUPULIFERÆ, Richard.**

**Corylaceae, Mirbel.**

**Character.**—Flowers unisexual: males amenantaceous; females aggregate or amenantaceous. Males: Stamens 5 to 20, inserted into the base of the scales, or of a membranous valvate calyx, generally distinct. Females: Ovaries crowned by the rudiments of an adherent (superior) calyx, seated within a coriaceous involucrum (cupule) of various figure, and with several cells and several ovules, the greater part of which are abortive; ovules twin or solitary, pendulous or peltate: stigmas several, sub sessile, distinct. Fruit a bony or coriaceous, 1-celled nut, more or less inclosed in the involucrum. Seeds solitary, 1, 2, or 3: embryo large, with plano convex, fleshy cotyledons, and a minute superior radicle. Trees or shrubs. Leaves with stipules, alternate, simple, often with veins proceeding straight from the midrib to the margin (Lindley).

**Properties.**—The prevailing quality of this order is astrigency, owing to the presence of tannic acid.

Besides the species presently to be described, the following may be here briefly referred to: Quercus tinctoria, or the Black Oak, is a native of America. Its bark, called quercitron, is used by dyers. In the United States it is employed medicinally, but it is said to be disordered to irritate the bowels. The large capsules or acorn cups of Quercus Egliops are imported from the Levant, under the name of Veloria. They are astringent, and are employed by dyers. A saccharine substance exudes from the leaves of Quercus mannifera in Kurdistan.

**110. QUERCUS PEDUNCULATA, Wild.**—THE COMMON BRITISH OAK.

**Quercus Robur, Linn.**

Sex. Syst. Monoeica, Polyandria.

(Cortex. L.—The Bark, E. D.)

**History.**—The oaks (Quercus of botanists) were held sacred by the Greeks, Romans, Gaus, and Britons. They are mentioned in the Old Testament. Both Dioscorides and Galen were acquainted with their astringent qualities. "Every part of the oak" (spar; Q. sessiliflora and pedunculata according to Fraas, but

---

2. Larsson and Millon. Comptes Rendus. t. xix. p. 317; and Annuaire de Chimie. p. 585. 1845. These writers state that salicylic acid was also produced; but Wohler and Frerichs found that hydruret of salicyl-cy never become changed into salicylic acid in its passage through the system.

---

---
according to Sibthorp Q. Ægilops), says Dioscorides, "but especially the liber, possesses an astringent property."

**Botany. Gen. Char.** Monœcious. **Male flowers:** Catkins lax and pendulous. Perianth lacerated. Stamens 5 to 10. **Female flowers:** Involucre scaly; the scales numerous, imbricated; combined with a coriaceous, hemispherical cup. Perianth 6-lobed, adnate to the ovary. Ovary 3-celled; 2 of the cells abortive. Stigmas 3. Nut 1-celled, 1-seeded, surrounded at the base by the cupule (acorn-cup). (Bot. Gall.)

Fig. 284.

**Sp. Char.—** Leaves deciduous, shortly-stalked, oblong-obovate, deeply sinuate; their sinuses rather acute, lobes obtuse. Fruits 2 or 3 upon a long peduncle (Hooker).

A large and handsome tree, remarkable for its longevity. Twigs round, smooth, grayish-brown. Leaves bright green, furnished with a single midrib sending off veins into the lobes. Male flowers yellowish; females greenish, tinged with brown.

The long peduncles which support the female catkins have given the name of pedunculata or long-stalked to this species of Quercus or Oak.

**Hab.—** Indigenous, growing in woods and hedges. Flowers in April. It is found in most European countries.

**Barking.—** In the spring, the barks of trees contain more astringent matter, and are more readily separated from the wood. The usual time for barking the oak is from the beginning of May to the middle of July. The barkers make a longitudinal incision with a mallet furnished with a sharp edge, and a circular incision by means of a barking-bill. The bark is then removed by the peeling-irons, the separation being promoted, when necessary, by beating the bark with the square end of the mallet. It is then carefully dried in the air, by setting it on what are called lofts or ranges, and is afterwards stacked.

**Description.—** Oak bark (cortex quercús) consists of pieces of from one to two feet long, which vary in their appearance according to the age of the stem or branch

1 Lib. i. cap. 142.  
from which they have been taken. The bark of young stems is thin, moderately smooth, covered externally with a silvery or ash-gray cuticle, and is frequently beset with lichens. Internally it is, in the fresh state, whitish; but, when dried, brownish, red, fibrous. The bark of old stems is thick, very rough externally, cracked, and wrinkled, and is usually of inferior quality.

**Composition.**—According to Braconnot,\(^1\) oak bark contains—tannic acid, tannates of lime, magnesia, potash, \&c., gallic acid, uncrystallizable sugar, pectin, and lignin.

The quantity of Tannin [impure tannic acid] obtained by Davy\(^2\) from oak bark, is as follows:

<table>
<thead>

</tbody>
</table>

Biggins\(^3\) obtained 30 parts of tannin from the bark of an oak felled in winter, while the same weight of the bark of an oak felled in spring yielded him 108 parts.

**Chemical Characteristics.**—Decoction of oak bark reddens litmus, and becomes dark blue or purple (tannate of iron) on the addition of sesquichloride of iron. A solution of gelatin causes a precipitate (tannate of gelatin) with it. It is somewhat remarkable, however, that a solution of emetic tartar causes no precipitate with the decoction. [If alcohol be added to the decoction, concentrated to the consistence of a syrup, it causes the precipitation of pectin. A decoction, rendered alkaline by a fixed alkali, deposits a gelatinous matter (pectic acid) on the addition of acetic acid. Braconnot.]

**Physiological Effects.**—The effects of oak bark are similar to those of other vegetable astringents containing tannic acid, and have been already described (see vol. i., p. 201).

**Uses.**—The principal value of oak bark in medicine arises from its astringent property. Thus we employ a decoction of it as a gargoyle in relaxed conditions of the uvula, and in chronic inflammatory affections of the throat;\(^4\) as a wash in flabby, ill-conditioned, or bleeding ulcers; as an injection in leucorrhoea, in piles, or in prolapsus of the uterus or rectum; as an internal astringent in old diarrhoeas, in the last stage of dysentery, in alvine hemorrhages, \&c. Poultices made of powdered oak bark have been applied with benefit to mortified parts.\(^5\) Mr. Lizar\(^6\) states that he has obtained "wonderful success" in the cure of reducible herniae by bathing the groin (the hernia having been previously reduced) three or four times daily with a warm inspissated decoction of oak bark, and then applying a truss.

The practice, however, is not a new one.\(^7\)

The inhalation of finely-powdered oak bark is said to have proved very beneficial in supposed cases of pulmonary consumption.\(^8\) I have already noticed (see vol. i., p. 175) the inspiration of impalpable powders of other astringents as a remedy for phthisis. Connected with this, the popular opinion of the exemption of operative tanners from phthisis pulmonalis deserves to be mentioned. Dr. Dods,\(^9\) who has paid some attention to this subject, concludes, that the popular notion is correct; and he ascribes the exemption to the inhalation of that peculiar aroma, or volatile matter, which is constantly arising from tan-pits during the process of tanning with bark." Hitherto, however, no sufficient evidence has been advanced to prove that tanners are exempt from the disease.

As a tonic, oak bark has been employed in medicine, but it is much inferior to the cinchona. Baths made of a decoction of this substance have been used by Dr. Eberle in the intermitents of very young children with benefit; and Dr. Fletcher,

---

5. *Barton, Collection towards a Mat. Med. of the United States.*
7. See the references in Plouquet's *Literature Medica,* t. ii. p. 297.
of Virginia, has recommended the same remedy in tabes mesenterica. The decoction, powder, and extract, have been taken internally in intermittents, but they are very apt to irritate the stomach. Dr. Cullen says, that both by itself, and joined with chamomile flowers, he has prevented the paroxysms of intermittents.

Administration.—Dose of the powder from half a drachm to one or two drachms.

Decoction Quercus, L. E. D.; Decoction of Oak Bark.—(Oak Bark, bruised, $\frac{3}{4}$ iss, $D$.; Water [Distilled, $L$] Oij [Oiss., $D$]. Boil down to a pint and strain.)—Used as a local astringent for various purposes, in the form of gargle, injection, or lotion. Administered in doses of $\frac{1}{3}$ii to $\frac{1}{3}$vi. Sometimes employed as a bath, especially for children.

III. Quercus Infectoria, Olivier.—The Gall, or Dyer's Oak.

(Galla; Tumor ramuli a Cynipe; Gallae tinctoriae excitatus, L.—Gallae, the excrescences formed by Diplolepis Gallae tinctorium, $D$.)

History.—Hippocrates employed the nutgall ($\chi\pi\kappa$) as an astringent, both internally and externally. Dioscorides describes it as the fruit of the oak; and the same error is found in the works of comparatively recent writers, as of Pomet.

Sp. Char.—Leaves ovate-oblong, sinuate-dentate, very smooth, deciduous. Fruit sessile, very long. Small tree or shrub, from four to six feet high. Stem crooked. Leaves on short petioles, with a few short mucronate teeth on each side. Acorn two or three times as long as the cupules.

Hab.—Asia Minor, from the Bosphorus to Syria, and from the Archipelago to the frontiers of Persia.

Formation of Galls.—The term gall (galla) is applied to an excrescence or tumour formed on any part of a vegetable, in consequence of the puncture of an insect.
In general, the insects which give rise to galls are the gall-flies, constituting the genus *Cynips*, and forming the tribe *Gallicolae* (*Diploleopariae*, Lat.) of the order *Hymenoptera*. But sometimes they are plant-lice, or *Aphidii* of the order *Hemiptera*. Thus the very astringent Chinese galls called *Woo* (*Dipterocarpus*), of which I have elsewhere¹ given a description, are produced, as the late Mr. Double-day² has shown, by an Aphidian.

The gall-flies (*Cynips*) are those by whose puncture the osseinal galls are produced, and to which, therefore, our attention must be principally directed. The females of these insects are supplied with an ovipositor, called by Latreille the borer (*terebra*), channelled with lateral teeth.—By means of this instrument they are enabled to perforate the foliaceous or cortical parts of plants for the purpose of depositing their eggs, along with an acrid liquor, in the wound thus made. The irritation thereby produced gives rise to an influx of the juices of the plant to the wounded part, and an excrescence is formed, which is termed a gall (*galla*). Here the insect usually undergoes its transformations: the egg produces the larva (or maggot), which feeds on the juices of the plant, and is changed into the pupa. This afterwards becomes the perfect insect (*imago*), and, perforating the gall, produces a small, round hole, through which it escapes from its prison-house.

The external form and appearance of galls are very constant when formed by the same insect, on the same part of the same plant; but the galls of different species of vegetables, and of different parts of the same plants, as well as those of the same vegetable species, produced by a different insect, vary considerably. There is reason for believing that the form and appearance of the gall is determined more by the insect than by the plant; for we sometimes have on the same oak two kinds of galls, of very dissimilar appearance, produced by different insects.

**Oak Galls.**—Most, if not all plants, but especially the oaks, are liable to the production of galls. The *oak galls* vary considerably in size, shape, texture, and other properties, according to the species and part of the oak in which they grow, and the insect by whose puncture they are produced. From their fancied resemblance to nuts, apples, currants, &c., they have been respectively called, *nut-galls*, *apple-galls*, *currant-galls*, *grape-galls*, *cherry-galls*, *artichoke-galls*.

The largest species of British oak-galls is the *oak-apple* or *oak sponge*, produced by *Cynips Quercus terminalis*. They are astringent, like nutgalls.

The *small round currant-galls* are produced by *C. Q. pedunculi*. They are scattered over the rachis of the anemum, giving it the appearance of a bunch of currants.

The *artichoke-gall* or *oak-strobile* is a beautiful foliose gall, produced by *C. Q. gemma*.

Galls of various species are produced on oak-leaves. One of the larger sorts is red and succulent, and has been called the *cherry-gall*. A smaller one is called by Reaumur the *currant-gall*. Mr. Westwood states that the large ones (as large as a boy’s marble) are formed by *C. Q. foliaria*.

The large *Mecora* or *Bussorah galls*, sometimes called *Dead-sea apples*, *mad-apples* (malia insania), or *apples of Sodom* (poma sodominita), are produced on the *Quercus infectoria* by a species of *Cynips* which Mr. Westwood calls *C. insanum*.

A very irregular, deeply-furrowed, angular gall is formed on the capsule of the *Quercus pedunculata* by the *Cynips Quercus calcy*is. This is the *acorn gall*. It is sometimes used in Germany by dyers as a substitute for muggalls under the name of *Knopen* or *Knobben*. These galls appear to me to be identical with some which I have received from M. Guibourt under the name of *gallon de Hongrie* ou du Piémont. The acorn, with its capsule, is usually attached to it. A very similar shaped gall, attached by its middle to a young branch, is frequently found intermixed; this M. Guibourt calls the *horned gall* (*galle corniculée*).

**Nutgalls.**—The nutgalls (*galla officinarum*) of commerce are produced by the *Cynips gallae tinctoriae* on the *Quercus infectoria*. Ollivier³ says that this insect lives on this species of Quercus only.

On the sides and at the ends of the branches and shoots of this tree, the female

¹ *Pharmaceutical Journal*, vol. iii. p. 284, 1844.
makes a puncture and deposits her egg. An excrescence is soon formed, within which the larva is developed, which is changed first into the pupa and then into

![Fig. 286. Mecca or Bussorah Galls.](image)

* a. Branch, bearing a gall.
* b. Section of a gall.

the imago. As soon as the perfect insect is produced, it eats its way out. If we examine those galls from which the animal has escaped, we observe externally a circular hole, of about a line in diameter, leading to a canal of from 2 1/2 to 3 1/2 lines long, which passes to the centre of the gall. But in those galls in which the insect has not put off its pupa state, we find neither an external hole nor an internal canal. In the imperforated gall, the part sometimes called "the kernel" is the cocoon of the insect in the pupa state (Kirby and Spence). Guibourt states that in the immediate envelop of the central cavity of the gall he detected starch grains, and, in the exterior covering, chlorophyll and volatile oil. Guibourt has also observed, around the spherical amyloidal mass, cells serving for the respiration of the insect.

Bluish black, heavy, not yet perforated. *Ph. L.*

Those galls from which the insect has escaped are commonly larger, lighter coloured, and less astringent: they are termed white galls.

The nutgalls of different countries vary in their size, shape, weight, and quality of surface.

1. *Levant Nutgalls (Gallæ Levantice).*—These are the ordinary nutgalls of the shops. They are in general about the size of a nut, somewhat round, tuberculated or warty; whence they were formerly called spiny or prickly galls (*gallæ a l'épine, gallæ spinosæ*), to distinguish them from the smooth French and other galls. They are imported from Syria and Turkey. The most esteemed Syrian galls (*gallæ syriace*) are the produce of Mosul on the Tigris; these are the Mosul galls (*gallæ mossulicæ*). The Aleppo galls (*gallæ haleppenses*) usually pass for Mosul galls. Tripoli galls (*gallæ tripolitanæ*) come from Tripoli (also called Taraplus or Tara-}

---

1 *Hist. Nat. des Drogues simples, 4me édit. t. ii. 1849.*
The Gall, or Dyer's Oak:—its Composition.

bulus, whence the corrupt name of "Tarabulous galls"), and are inferior to the
Aleppo galls. The *Turkey galls* (gallæ turcicæ) usually come from Constantinople
or Smyrna. *Smyrna galls* (gallæ smyrnenses) are not so heavy, are lighter
coloured, and contain a larger admixture of white galls than those brought from
Aleppo. The galls brought from Bombay (East India galls) are probably the
produce of Persia or neighbouring parts.¹

In commerce, three kinds of Levant galls are distinguished, viz., *black* or *blue,*
green, and white; but there is no essential distinction between the first two.

a. *Black or blue nutgalls* (gallæ nigrae seu cervulæ); *green nutgalls* (gallæ
virides).—These are gathered before the insect has escaped, and are called by the
natives gæl. They vary from the size of a pea to that of a hazel-nut, and have a
grayish colour. The smallest have a blackish-blue tint, and are distinguished by
the name of *black or blue galls*; while the larger and greener varieties are called
*green galls.* Externally they are frequently tuberculated, but the surface of
the tubercles and of the intervening spaces is usually smooth. Their texture is
compact, but fragile. They have no odour, but a styptic and powerfully astringent
taste.

b. *White galls* (gallæ albae).—These are for the most part gathered after the
insect has escaped, and hence they are perforated with a circular hole. They are
larger, lighter coloured (being yellowish or whitish), less compact, less heavy, and
less astringent. They are of inferior value.

c. *Marmarine nutgalls* (gallæ marmorines, Guibourt) of the French writers
are a sort of Levant gall about the size of the black or blue galls, but without
tuberces or warts. The surface, however, is dull and roughish, something like
orange berries. Their shape is round, with sometimes a little elongation where the
peduncle is attached.

d. *Small Aleppo nutgalls.*—Occasionally there is imported from Aleppo a small
sort of nutgall, called the *coriander gall.*

Somewhat larger than these is another sort of small Aleppo gall, called the *small
crowned Aleppo galls* (gallæ halepenses coronatae). They are about the size of a
pea, or a little larger, and crowned superiorly by a circle of points or tubercles like
the fruit of the myrtle or Eugenia. Although very small, they are often perforated
by a large hole, so that they must have attained their maximum size; and,
therefore, are a distinct sort from the usual Aleppo kind.

Somewhat larger than these, and having a speckled surface, is a sort which I
have received under the name of *Turkish diamonds.*

2. *European Nutgalls.*—Various sorts of nutgalls are produced in Europe.
The *Istria nutgalls* are intermediate in size between the usual Levant galls and the
small Aleppo sort. They are somewhat turbinate or pear-shaped, wrinkled, and
usually have a short peduncle. The *Morea nutgalls* are about the size of the pre-
ceding. *French nutgalls* are spherical, very light, usually very smooth or even
polished, but sometimes very slightly wrinkled. *Hungarian, Italian, Bohemian,
&c. nutgalls* are but little known in England.

Composition.—Nutgalls were analyzed by Sir H. Davy,² who obtained the fol-
lowing results:

\[
\begin{array}{c}
\text{Matter soluble in water } = 37; \text{ viz.} \\
\text{Tannin} & 26.0 \\
\text{Gallie acid, with a little extractive} & 6.2 \\
\text{Mastic and matters rendered insoluble by evaporation} & 2.4 \\
\text{Carbonate of lime and saline matter} & 2.4 \\
\text{Matter insoluble in water (Lignin)} & 63.0 \\
\end{array}
\]

Good Aleppo nutgalls

Pouzon³ found in 100 parts of nutgalls the following constituents: *tannic* acid
40.0, *gallic* acid 3.5, *ellagic* acid and *insoluble matter* 50, *extractive colouring
matter 6.5 = 100.0.

¹ *Mai. Indicae*, vol. 1. p. 145.
² *Phil. Trans. for 1830.*
³ *Ann. de Chimie et de Physique*, t. liv. p. 337.
1. Tannic Acid (see p. 325).
2. Gallic Acid (see p. 326).
3. Ellagic or Bezoarine Acid (Acidum Ellagicum vel Bezoaricum), C_{6}H_{14}O_{3}H.O.—Discovered by Bracoonot, who called it ellagic acid, from the French word galle spelt backwards. It is probably produced by the slow decomposition of the tannin contained in the nutgall. It is a yellowish gray insipid powder, scarcely soluble in cold water, a little more so in alcohol, but insoluble in ether. Like the tannic and gallic acids it forms a bluish black precipitate with the persalts of iron. Hot nitric acid, according to Bracoonot, gives it a blood-red colour. The acid has recently acquired additional interest in consequence of the discovery by Mr. Thomas Taylor (subsequently confirmed by Merklein and Wöhler) that the Oriental Bezoar is an ellagic acid calxius formed in the intestines of animals (usually a species of wild goat, termed by the Persians Pasen), which feed on vegetable substances containing tannin, iron which the ellagic acid is produced. Ellagic acid, therefore, must be regarded as identical with bezoarine (Bezoarstoff of John).

Chemical Characteristics.—Infusion of nutgalls reddens litmus paper, forms an inky compound (tanno-gallate of iron) on the addition of a sesquisalts of iron, and a yellowish white precipitate (tannate of gelatin) with a solution of gelatin. If a piece of skin, depeilated by lime, be immersed in the infusion, and agitated with it from time to time, all the tannic acid is absorbed, the filtered liquor striking a blue colour (gallate of iron) with the sesquisalts of iron, but giving no precipitate with a solution of gelatin. Infusion of galls forms precipitates (metallic tannates or tanno-gallates) in many metallic solutions; it also produces a precipitate (a tannate) in aqueous solutions of the vegetable alkaloids.

Physiological Effects.—As nutgalls contain a larger portion of tannic acid than any other known vegetable production, they possess in the highest degree the properties of an astringent (see vol. i. pp. 200 and 243).

Uses.—The following are the principal uses of nutgalls:

1. As a tonic in intermittent.—Notwithstanding Poupart's favourable report of the use of galls in these cases, they scarcely deserve notice, as we have in arsenic, cinchona, and sulphate of quinia, much more effective and certain febrifuges.

2. As an astringent in hemorrhages, especially passive alvine hemorrhages.

3. In chronic mucous discharges, as old diarrhoeas.

4. As a chemical antidote (see vol. i., p. 198).—Nutgalls may be given in poisoning by ipecacuanha, emetina, the organic alkalies generally, and those vegetable productions whose activity depends on an organic alkali; as opium, white hellebore, colchicum, nux vomica, &c. Their efficacy arises from the tannic acid, which combines with the vegetable alkali to form a tannate possessing less activity than the other salts of these bases; perhaps because of its slight solubility. Nutgalls

---

\(^3\) Brande's Manual of Chemistry, 1849.

\(^4\) Discrepancies arise from the strength of the solutions as well as from their acid or basic characters, so that neutral solutions should as far as possible be used.
are recommended as an antidote in cases of poisoning by emetic tartar, but I very much doubt their efficacy (see vol. i. p. 670).

5. As a topical astringent.—Nutgalls are applicable in any cases requiring the topical use of a powerful vegetable astringent. Thus, in the form of gargle, in relaxation of the uvula; as an injection, in gleet and leucorrhœa; as a wash, in flabby ulcers, with profuse discharge; prolapsus ani seu vaginae; in the form of ointment, in piles, &c.

Administration.—The dose of the powder is from ten to twenty grains. Nutgalls are also used in the form of infusion and tincture.

Roasted nutgalls (galloë torrefactæ) are used in the manufacture of copying-ink (see p. 329).

Besides the following official formulae for the use of galls, others have been published by Mouchon.1

1. INFUSUM GALLÆ; Infusion of Gall.—Prepared by digesting 5iv of coarsely powdered nutgalls in $\frac{1}{2}$vj of boiling water.—Employed as a chemical antidote and as a reagent or test (see ante, p. 324). The dose is from $\frac{2}{3}$ss to $\frac{3}{4}$j; or, in cases of poisoning by the vegetable alkaloids, $\frac{1}{3}$iv.

2. TINCTURA GALLÆ, L. D. [U.S.]; Tincture of Galls.—(Galls, bruised, 5v; Proof Spirit Oij. Macerate for seven [fourteen, D.] days, and filter. [Galls, bruised, $\frac{5}{3}$iv; Diluted Alcohol Oij. Macerate for fourteen days, and filter, U. S.]) “This tincture may be prepared either by digestion or percolation, as directed for tincture of capsicum,” E.)—A powerful astringent. Dose from $\frac{3}{4}$ss to $\frac{3}{4}$j. Diluted with water, it forms a very useful and convenient astringent gargle and wash. Its principal use is as a chemical test, especially for the persalts of iron, gelatin, and the vegetable alkaloids. After it has been kept for some time its tannic acid becomes converted into gallic acid, and it then ceases to occasion precipitates in solutions of gelatin and of the vegetable alkaloids.

3. UNGUENTUM GALLÆ, D. [U.S.]; Ointment of Galls.—(Galls, in very fine powder, 3j; Ointment of White Wax 5vj. Mix them)—(Galls, in powder, 3j; Lard 3vj. Mix them, U. S.)—Astringent. Mixed with zinc ointment it is applied to piles after the inflammatory stage is passed. The above is Dr. Cullen’s formula; but Mr. B. Bell recommends an ointment composed of equal parts of powdered galls and hog’s lard or butter, in external hemorrhoidal swellings. [A smoother ointment, and one which leaves no gritty, rough deposit on irritable surfaces, is prepared by adding 3j of Aqueous Extract of Galls to 5j of Simple Ointment.—Ed.]

4. UNGUENTUM GALLÆ COMPOSITUM, L.; Unguentum Gallinæ et Opium, E.; Compound Ointment of Galls.—(Galls, in fine powder, 3vj; Opium, powdered, 5iss; Lard 2vj. Mix.—The Edinburgh College orders of Galls, in fine powder, 3j; Opium, in powder, 3j; Axunge 5j)—An excellent astringent application to blank piles (i.e. piles without hemorrhage) and prolapsus ani. The opium diminishes the pain which the galls might otherwise occasion, where the hemorrhoidal tumours are very sensible. From 3ss to 3j of camphor is frequently added to this ointment.

5. ACIDUM TANNICUM, L. D. [U.S.]; Acidum Quercitannicum; Tannic Acid: in the impure state called Tannin, the Tanning Principle, or Materia Scytophilia (καυνοβραχῖον, belonging to curriers).—Extracted from nutgalls by ether in the percolation or displacement apparatus. The ether employed is that of commerce (which contains about 10 per cent. of water). The tannic acid at first dissolves in the ether, but is afterwards precipitated, in the form of a thick syrup, by the water contained in the ether. The syrupy layer is to be repeatedly washed with pure ether, and afterwards evaporated in vacuo, or at a temperature not exceeding 212° F. The residue is almost pure tannic acid.

Galls, in tolerably fine powder, \( \frac{3}{2} \) vij; Sulphuric Ether Oij; Distilled Water \( \frac{3}{2} \) v. Incorporate the water and ether by agitation, and pour the resulting solution, in successive portions, upon the galls, previously introduced into a glass or porcelain percolator. The liquid which accumulates in the lower bottle will consist of two distinct strata, the heaver of which is to be separated and evaporated to dryness, finally applying an oven heat, which, however, should not exceed 219°. From the lighter liquid the ether may be removed by distilling it by means of a water-bath, and with the aid of a Liebig's condenser.—D.

Tannic acid is a spongy, brilliant, light, odourless white, or commonly yellowish, solid. It dissolves in water, alcohol, and ether; but less so in ether than in alcohol. In the solid state it is unalterable in the air; but, dissolved in water, it absorbs oxygen, and is transformed into carbonic acid, which escapes, and gallic acid, which remains in solution: hence it should be dissolved only at the time we are about to use it.

The following are the characteristics of this substance: It has an intensely astringent taste, and produces, with a solution of gelatin, a white precipitate (tannate of gelatin); with a solution of a sesquisalt of iron, a deep blue compound (tannate of iron; see vol. i. p. 711); and with solutions of the vegetable alkalies, white precipitates (tannates) slightly soluble in water, but very soluble in acetic acid. The mineral acids also cause precipitates with concentrated solutions of tannic acid, as do the alkalies and their carbonates. Gelatinous alumina rapidly absorbs tannic acid from its solution, and forms an insoluble compound with it.

Almost colourless; its solution in water is strongly astringent; with a solution of isinglass it produces a white precipitate. In other respects it agrees with the characters assigned to gallic acid. Ph. Lond.

Tannic acid is composed of \( \text{C}_{3}\text{H}_4\text{O}_3 = \text{C}_6\text{H}_3\text{O}_6\text{H}_3\text{O} \); consequently its equivalent or atomic weight is 212. Its symbol is \( \text{Ta} \text{n}_3\text{H}_3\text{O}_6 \); or \( \text{Q}_4\text{H}_3\text{O}_6 \).

Tannic acid is employed in medicine, in chemistry, and in the arts.

Considered as a medicine, tannic acid is a powerful agent of the astringent class. As a topical remedy it is probably the most powerful of all vegetable astringents or styptics. Its chemical action on fibrine, albumen, and gelatin explains this. It is the active principle of a very large proportion of vegetable astringents (see vol. i., pp. 200 and 243). Given to a dog in doses of from 7\( \frac{1}{2} \) grains to about 93 grains, it did not affect the health of the animal: it caused constipation, but its appetite remained the same. The urine gradually became darker coloured and opake, and was found to contain both gallic and pyrogallic acids and humus-like substances. The tannic acid had become converted into these bodies in its passage through the animal system. The gallic acid was detected by the blackish blue precipitate produced by the persalts of iron, and by no precipitate being produced with gelatin. Pyrogallic acid was detected by the bluish black precipitate produced by the protosalts of iron. On the human subject tannic acid also operates as a constipating agent when given in a sufficient dose and frequently repeated. Cavara\(^2\) states that 2\( \frac{1}{2} \) grains taken three days successively produced this effect on himself. The remote effects of tannic acid are not so obvious, but they appear to be astringent, though in a much feebler degree. As the tannic acid becomes changed into gallic acid in its passage through the system, it is probably the latter agent which operates on remote parts as an astringent when tannic acid is administered. If this opinion be correct, tannic acid would act, as Dr. Garrod\(^2\) has suggested, less powerfully as a remote astringent than an equal weight of gallic acid. But, as a topical astringent, tannic is far more powerful than gallic acid; because its chemical reaction on albumen, gelatin, and fibrine is more energetic.

Tannic acid is used as an astringent chiefly in hemorrhages and profuse secretions; and also to constringe relaxed fibres. In hemorrhages, it has been used both topically, as a styptic (in bleeding gums, piles, and uterine hemorrhage), and remotely, as an astringent (in hemorrhage from the lungs, stomach, bowels, kidneys,

---

\(^1\) Wöhler and Freslels, Chemical Gazette, vol. vi. p. 231, 1848.

\(^3\) Lancet, Dec. 30, 1848.
and uterus). In chronic fluxes it has likewise been employed both as a topical and a remote remedy: topically in gonorrhoea, gleet, leucorrhoea, and ophthalmia; remotely in pulmonary catarrh, diarrhoea, dysentery, leucorrhoea, gonorrhoea, and cystirrhoea. To restrain the phthisical sweating it has been recommended by Charvet and others, and Giadorow¹ states that, given in combination with opium, he cured (?) two cases of diabetes by it. To constringe fibres, it is applied to spongy gums and prolapsed bowel. As an application to sores, it has been employed by Ricord in chancrets, and by Mr. Druit² in sore nipples. Dr. Scott Alison³ has recently recommended its use in various other cases: as a tonic or peptic in dyspepsia; as an "histogenic" to promote the genesis and improve the quality of the blood, in rickets, &c.; as a nerve in nervous debility and languor; and to arrest or retard the growth of heterologous formations (tubercle, malignant disease, &c.). It has likewise been given as an antidote to check excessive vomiting from ipecacuanha or emetina.—Tannic acid may be administered in doses of from 3 to 10 or more grains, in powder, pill, or solution. When we employ it as a remote agent, the pill-form seems to be the most appropriate mode of exhibition.—As a lotion or injection, it may be used in the form of aqueous solution containing from 4 to 6 or more grains in the fluid ounce. It has also been employed in the form of ointment composed of 5ij of the acid dissolved in 15ij of distilled water and mixed with 3xij of lard.

In chemistry, tannic acid is employed as a reagent or test. Its solution should be fresh made when used.

In the arts it serves various useful purposes. It is the active principle of the tanning substances. In the manufacture of white wines it is used to coagulate the substance called glaïadine, which is apt to excite the viscous fermentation in these wines.

6. ACIDUM GALICUM, L. D. [U. S.]; Gallic Acid.—It is usually prepared by exposing for a long time an infusion of nutgalls to the air; removing now and then a mouldy skin which forms on the surface of the liquid. A sediment of impure gallic acid is obtained, which requires to be purified by solution in boiling water, decolorized by animal charcoal, and crystallized.

In this process the tannic acid of the nutgalls absorbs atmospheric oxygen, and is converted into gallic acid, carboxic acid, and water.

\[
\begin{align*}
\text{C}_7\text{H}_6\text{O}_5\text{O}^+ & + \text{O}^- = 2(\text{C}_7\text{H}_6\text{O}_4)\text{O}^- + 4\text{CO}_2 + 2\text{H}_2\text{O} \\
\text{Hydrated} & \text{tannic acid.} \\
\text{Gallic} & \text{acid.} \\
\text{Carbonic} & \text{acid.} \\
\text{Water.} & 
\end{align*}
\]

This process is favoured by the presence of a nitrogenized matter which acts as a ferment; and the decomposition is termed the gallic fermentation. The mouldy skin which forms on the surface is called mycoderma, and resembles mother of vinegar (see ante, p. 85).

Galls, in coarse powder, lb. j.; Distilled Water, as much as may be necessary. Having placed the galls in a porcelain dish, pour on as much water as will convert them into a thick paste, and keep them in this moistened condition for six weeks, at a temperature of between 60° and 70°, adding water from time to time, so as to supply what is lost by evaporation. Let the residue be boiled for twenty minutes, with forty-five ounces of water, and then placed on a calico filter. The filtered solution, on cooling, will afford a copious precipitate. Let this be drained on a calico filter, then subjected to strong expression, after having been first enveloped in blotting paper, and again dissolved in ten ounces of boiling water. When, upon ceasing to apply heat, the solution has cooled down to 80°, pour it off from the crystals which have formed, and, having washed these with three ounces of ice-cold water, dry them—first in blotting paper, and finally by a steam or water heat.

By boiling the undissolved portion of the galls with forty-five additional ounces of water, filtering into a capsule containing the liquor decanted from the crystals formed in the preceding process, evaporating down to the bulk of ten ounces, and cooling to 80°, an additional quantity of the crystallized acid will be obtained.

¹ *Annales universiatis, di Medicina*, quoted by Dr. Danglison, in *his New Remedies*, 5th edit. 1846.
VEGETABLES.—NAT. ORD. CUPULIFERAE.

Or.: Galla lb. j; Oil of Vitriol of commerce 1/2 xvi; Water Ov. 3xiv. Steep the galls for twenty-four hours in one pint of the water, then transfer them to a glass or porcelain percolator, and pour on a pint and a half of the water in successive portions. Dilute five ounces of the oil of vitriol with an equal bulk of water, and, when the mixture has cooled, add it to the infusion obtained by percolation, stirring well, so as to bring them into perfect contact. Let the viscid precipitate which forms be separated by a filter, and to the solution which passes through, add five ounces more of the oil of vitriol, which will yield an additional precipitate. This being added to that previously obtained, let both be enveloped in calico, and subjected to powerful pressure. Dissolve the residue in the rest of the oil of vitriol, this latter being first diluted with what remains of the water; boil the solution for twenty minutes, then allow it to cool, and set it by for a week. Let the deposit which has formed at the end of this period be pressed, dried, and then dissolved in three times its weight of boiling water, clearing the solution, if necessary, by filtration, and, when it has cooled down to 80°, decant the liquid from the crystalline sediment which has formed, and wash the latter with three ounces of ice cold water. Finally, let it be transferred to blotting paper, and, when deprived by this of adhering liquid, let it be dried perfectly, at a temperature not exceeding 212°.

The gallic acid obtained by either of the preceding processes may be rendered nearly white by dissolving it in twenty times its weight of boiling distilled water, and causing the solution to traverse a stratum of prepared animal charcoal spread upon a calico filter. When the liquid passes through colourless, it should be evaporated to one-sixth of its volume, and then suffered to cool, in order to the separation of the crystallized acid.—D.

Pure gallic acid is a colourless, crystallizable acid, with an acidulous and styptic taste. It is soluble in water, alcohol, and slightly so in ether. It produces a deep blue colour with the salts of the sesquioxide of iron, in which circumstance it agrees with tannic acid, but it differs from the latter acid in not precipitating gelatin or the salts of the alkaloids. To detect gallic acid mixed with tannic acid, the latter is to be previously removed from its solution by immersing in it a piece of skin depilated by lime. The tannic acid is absorbed. The gallic acid may then be detected by the salts of the sesquioxide of iron.

Colourless; destroyed by fire. Soluble both in water and in rectified spirit. It strikes a bluish black colour with solutions of the sesquioxide of iron; but produces no precipitate with a solution of isinglass. Ph. Lond.

It does not occasion any precipitate with the salts of the protoxide of iron. By this it is distinguished from pyrogallic acid.

Gallic acid consists of C7H4O5; hence its equivalent or atomic weight is 185. When heated to 410° or 420° F., it gives out carbonic acid, and is resolved into pyrogallic acid (C9H4O4). If this acid is heated to 480° F., it gives out water and becomes metagallic acid (Cu3H4O5).

Gallic acid is employed in medicine as an astringent; but as a topical agent it is greatly inferior to tannic acid. Unlike the latter acid it causes precipitates neither in gelatinous nor in albuminous solutions: and a piece of skin does not absorb gallic acid from its aqueous solution, as it does tannic acid from its solution. Its chemical action on the constituents of the animal tissues is thus much weaker than that of tannic acid. No obvious effects result from the introduction of a few grains into the stomach. Twenty-four grains have produced a sweetish taste and a slight feeling of internal heat; but no other effect. It has been administered in doses of from fifteen to thirty grains against the Tinea Solium, but without any benefit. For the reasons already stated (see ante, p. 326) it is probable that, in equal doses, it is more powerful, as a remote astringent, than tannic acid. Dr. Todd says that in all cases of hemorrhage, whether haemoptysis, hematemesis, haematuria, or any other form dependent on hemorrhagic tendency, he considers it to be the best styptic we possess. The dose of it is from three to ten grains or more three or four times a day. It may be used in the same forms as tannic acid (see ante, p. 326).

7. ACIDUM PYROGALLICUM; Pyrogallic Acid.—At a temperature of from 410° to 420° F., gallic acid is converted into pyrogallic acid and carbonic acid.

1 Chevallier, Dict. des Droguers, t. i. p. 93, Paris, 1827.
Pyrogallic acid is a crystallizable volatile acid. It is more soluble in water than gallic acid. It produces a very intense blue colour with the salts of the protoxide of iron, and by exposure to the air it absorbs oxygen, and is converted into a dark brown substance, which is insoluble in water and alcohol.

Pyrogallic acid, in an impure form, is employed in the preparation of a hair dye and of copying ink. By the dry distillation of galls, it is obtained partly in the form of a sublimate, partly in the fluid form. The sublimate and fluid are to be dissolved in distilled water, the solution deodorized by animal charcoal, concentrated by evaporation, and then mixed with spirit of wine and some agreeable volatile oil. The resulting compound is a hair-dye, which stains the hair dark brown; and the tint is not removed by sweat or moisture. It must be cautiously applied, as it stains the hands. Roasted nutgalls are used in the manufacture of copying ink on account of the dark colour which the pyrogallic acid produces with the sulphate of the protoxide of iron.

[Quercus Tinctoria, Bartram.—Black or Dyer's Oak.

Sex. Syst. Monoeica, Polyandria.

Gen. Char.—See ante, p. 318.

Sp. Char.—The leaves are obovate or oblong, sinuate, lobed, pubescent beneath. Male flowers in slender, long, filiform aments. Cup turbinate. Acorn small, ovoid, flattened at top.

This is one of the largest forest-trees of the United States, attaining, in favourable situations, the height of ninety or one hundred feet, with spreading branches, and a rough, dark-coloured bark. The bark when separated is thick and rugged, full of fissures, and black externally; internally, it is fibrous and of a red colour increased by drying. It breaks with a rough fracture. That obtained from the young shoots and smaller branches is smoother externally, and the inner fibres are finer. The odour is strong, and the taste is bitter and styptic, tinging the saliva yellow when chewed. The cellular integument contains a yellowish-brown colouring principle. The interior layer when separated constitutes Quercitron Bark, used for the purpose of dyeing; it is shipped to Europe.

In consequence of the colour imparted to leather, it is not as much used for tanning. As it soils the clothes an objection is urged against it in medicine.

The medical properties and uses are the same as those enumerated under Q. pedunculata.

Quercus Alba, Linn.—White Oak.

Sex. Syst.—Monoeica, Polyandria.

Gen. Char.—See ante, p. 318.

Sp. Char.—Leaves obovate, oblong; obliquely divided into obtuse lobes; segments, oblong entire; cup hemispherical, tuberculated; acorn ovoid, oblong; fruit in pairs.

This tree is less elevated than the Q. tinctoria. It forms, however, a larger and more regularly-expanded head, with numerous horizontal branches. The trunk and branches have a whitish hue, hence the name White Oak. The leaves are of a silvery appearance, with a hoary under surface. The young leaves are covered with a fine silky down.

The bark is rough externally, of a light colour; the effete epidermis being arranged in flat layers. On drying, the internal layer becomes brown. It breaks with a stringy fracture. The odour is decided and tan-like; taste astringent and bitter. This bark is used in tanning. For medicinal purposes it is preferred to the black oak.

Decoction Quercus Alba, U. S.; Decoction of White Oak Bark.—(Take of White Oak Bark, bruised, an ounce: Water a pint and a half. Boil down to a pint and strain.)—Used as the Decoction Quercus, p. 320.]

112. Quercus Suber, Linn.—The Cork-Tree.

Sez. Syst. Monœcia, Polyandria.

(Cortex.)

This season of the year is selected when the bark adheres the most firmly to the wood, in order that the cork may be raised without endangering the separation of the liber from the alburnum. By this precaution, the trees are not at all injured by the corking process; nay, they are said to be more healthy and vigorous than when the cork is allowed to accumulate on their stems. The trees yield these crops from the age of fifteen to one hundred and fifty years.

To remove the cork, an incision is made from the top to the bottom of the tree, and a transverse circular incision at each extremity; the cork is then stripped off. To flatten it, a number of layers are piled up in a pit of water, and loaded with weights to keep them down. Subsequently they are dried, and in that state exported. Our supply is principally derived from Spain and Portugal. To close the transverse pores, cork is charred.

The physical properties of cork are too well known to need description. Its leading character is elasticity. In this respect it is similar to the wood of Anona palustris, called cork wood, and which is used in Jamaica by the country people, instead of corks, to stop up their jugs and calabashes. When thin slices of cork are examined by the microscope, they present a cellular appearance, the cells being four-cornered and tabular.

The most important chemical examinations of cork are those of Chevreul and Doepping. According to Chevreul, cork contains traces of a volatile oil, wax (cerium), soft resin, red and yellow colouring principles, tannin, a nitrogenous brown substance, gallic acid, acetic acid, carboarsalts, and suberin.

The substance to which the name of suberin has been given is the body which remains after cork has been successively treated with alcohol, ether, water, and diluted hydrochloric acid. In its form and physical characters it differs but little from ordinary cork. According to Doepping, it cannot be obtained pure, but always contains cork cellulose \((C_6H_{10}O_5)_n\), some cork wax \((C_{20}H_{30}O_4)\), and a small quantity of a nitrogenous body. He found it to consist of carbon 67.8, hydrogen 2.3, and oxygen 21.12. When cork is treated with nitric acid, the

5 Annales d. Chem. u. Pharm. Bd. xlv. S. 296, 1813; also The Chemical Gazette, July 1, 1843.
suberin yields suberic acid (C\textsubscript{9}H\textsubscript{10}O\textsubscript{6}), which imparts a peculiar character to cork, and to all barks containing cork.1

The uses of cork for making floats for fishermen's nets, anchor-buys, stoppers to vessels (obtura menta cadorum), and women's winter shoes, are mentioned by Pliny. On account of the astringent matter which it contains, cork is an improper substance for closing vessels containing chalybeate liquids (especially such as are intended for analysis), as the iron is in part absorbed by the cork.

Cork was formerly employed in medicine. Reduced to powder, it was applied as a stptic: hung about the necks of nurses, it was thought to possess the power of stopping the secretion of milk; lastly, burnt cork, mixed with sugar of lead and lard, has been used as an application to piles.

2. Cortex Alcornoque Europææ; European Alcornoque Bark; Cork-Tree Bark.—The bark of the cork-oak, which I received from Spain under the name of alcornoque bark, bears considerable resemblance to oak bark, and was probably obtained from the younger branches of the cork-tree. It is ash-gray externally, and wrinkled or grooved internally. The bark imported from Italy, Spain, and Barbary, under the name of cork tree bark, and which is used by tanners, appears to be the inner bark of older stems. It consists apparently of the third and fourth layers above mentioned. It is in fibrous or stringy pieces, externally dusty red, internally deeply grooved or furrowed. It has a very little colour, and an astringent taste. For tanning purposes the Italian bark is considered inferior to the Spanish and Barbary barks. In its medicinal properties, European alcornoque bark resembles oak bark. It owes its astringency to tannic acid. Its powder, in the dose of a drachm, has been used in hemorrhages and diarrhoea.3

3. Cortex Alcornoque Americanæ; American Alcornoque Bark.—This is the genuine alcornoque bark of French and German pharmacologists. The Spanish colonists have applied the name of alcornoque bark to one or more American barks which possess some real or fancied resemblance to the alcornoque bark of their mother-country. Humboldt4 says that the Baeotichia vorticoides (HBK.) is called by the inhabitants of the districts where it grows, in South America, the alcornoque. In another place,5 he states that the same name is given to a Malpighia (Byronia) on account of the suberous bark of the trunk. Nees von Esenbeck6 considered byronia crassifolia (Malpighia crassifolia, Auct.) to be the source of the American alcornoque bark. The bark which comes from South America, and is considered to be genuine alcornoque bark, occurs in large, flat, occasionally arched pieces, having some resemblance to coarse, flat Cinchona bark. The epidermis is usually wanting. Externally the bark is reddish, or dark cinnamon brown; internally it is pale. The taste is slightly bitter. It has been repeatedly subjected to analysis. Blitz7 gives as the constituents—peculiar crystalline matter (al-kornin), 1.15; matter soluble in alcohol, not in ether (oxidized tannin?), 1.07; tannin with a lime salt, 14.27; gummy extractive with starch, a nitrogenuous substance, and a supersalt of lime, 33.74; woody fibre and loss, 47.71; ashes of the woody fibre, 1.46=100.0

American alcornoque bark possesses astringent properties. It was introduced into European practice, in 1811, as a remedy for phthisis, but, after a short trial, it soon fell into disuse; and there are no grounds for supposing that it has any curative powers whatever in this disease.—Dose, in powder, $\frac{3}{4}$ to $\frac{3}{2}$. It may also be used in the form of infusion or decoction (prepared with $\frac{3}{4}$ of bark and $\frac{5}{4}$ of water), in doses of $\frac{3}{4}$ or $\frac{1}{2}$. The dose of the extract is from gr. x to $\frac{3}{4}$.

Order XXVII. ULMACEÆ, Mirbel.—ELMWORTS.

Characters.—Flowers hermaphrodite or by abortion unisexual, in loose clusters, never in catkins. Calyx membranous, imbricated, campanulate, inferior, irregular. Petals 0. Stamens definite; inserted into the base of the calyx; erect in stamination. Ovary superior, 1- or 2-celled; ovules solitary; pendulous; stigmas 2, distinct. Fruit 1- or 2-celled, indeliscent, membranous, or drupaceous. Seed solitary, pendulous; albumen none, or in very small quantity; embryo straight or curved, with foliaceous cotyledons; radicle superior.—Trees or shrubs, with rough, alternate, deciduous leaves, and stipules.

Properties.—The plants of this order bear some analogy to those of Cupuliferæ, in their chemical and medicinal properties. Their bark contains tannic acid; combined, however, with mucilaginous and bitter matters. Hence it is reputed astringent and tonic.

2 Alcornoque is the Spanish name for the cork-oak. It is of Arabic origin, being derived from dorque, signifying "denuded or badly clothed," adding the article al, changing d into c, and introducing the syllable no into the middle of the word. (Diccionario de la Lengua Castellana, compuesto por la Real Academia Española, 1726-39.)

8 For further details respecting alcornoque bark, the reader is referred to a paper by the author in the Pharmaceutical Journal, vol. vi. p. 369, 1847.
VEGETABLES.—NAT. ORD. ULMACEÆ.

Dr. M'Dowall, of Virginia, has proposed the bark of Ulmus fulva for bougies, tents, catheters, &c.

113. ULMUS CAMPESTRIS, Linn.—THE COMMON SMALL-LEAVED ELM.

**Sex. Syst. Pentandria, Digynia.**

(Cortex interior, L.)

**History.**—Dioscorides⁸ speaks of the astringent property of the bark of the elm (arreté), as does also Pliny.⁹

**Sp. Char.**—Leaves doubly serrated, rough. *Flowers* nearly sessile, 4-cleft. *Fruit* oblong, deeply cloven, naked (Sir J. E. Smith).

A large tree, with rugged bark. By the latter character it is readily distinguished from *Ulmus glabra*, which has a smooth, dark, lead-coloured bark.

**Hab.**—Southern parts of England. *Flowers* in March or April.

**Description.**—The official part of the elm is the inner cortical portion, or *liber*. To obtain it, the bark should be separated from the tree in spring; and, after the epidermis and a portion of the external cortex have been removed, the *liber* should be quickly dried.

As met with in the shops, the *inner elm bark* (cortex ulmi) consists of thin tough pieces, which are inodorous, and have a brownish-yellow colour, and a mucilaginous, bitter, very slightly astringent taste.

**Composition.**—According to Rink,¹ 100 parts of elm bark contain—resin 0.63, *gum* and *mucus* 20.3, impure gallic acid (tannin?) 6.5, *oxalate of lime* 6.3 (?), *chloride of sodium* (?) 4.6.

1. **Tannic Acid.**—Davy⁴ states that 480 grs. of elm bark yielded 13 grs. of tannin.

2. **Ulmic Acid; Ulmin.**—On many trees, especially the elm, there is not unfrequently observed a substance which was supposed to be a morbid production. When dried, it consists of a mucilaginous matter, and carbonate or acetate of potash. By the combined agency of the air and the carbonate, the organic matter is altered in its properties, and is converted into a brown substance, which combines with the potash. This brown matter has been termed *ulmin*, or *ulmic acid*. It may be formed, artificially, by a variety of processes; as by heating a mixture of wood and potash, by the action of sulphuric acid on vegetable matters, and by other methods.

**Chemical Characteristics.**—Infusion of elm bark becomes green (*tannate of iron*) on the addition of a salt of the sesquisioxide of iron, and forms a precipitate (*tannate of gelatin*) with a solution of gelatin.

**Physiological Effects.**—The effects of elm bark are those of a mild astringent tonic, containing a considerable quantity of mucilage, which gives it a demulcent property. Hence, in the classification of Richter,⁶ it is arranged as a *mucilaginous astringent*. The decoction, taken in full doses, accelerates the pulse and acts as a diaphoretic and diuretic.

**Uses.**—Lyonson⁵ recommended the decoction of this bark in cutaneous eruptions, and Dr. Lettsom⁶ found it successful in ichthysis. It has now fallen almost into disuse. It has been employed as a cheap substitute for sarsaparilla.

**Administration.**—Used only in the form of decoction.

**Decoction of Elm Bark.**—(Fresh Elm Bark, bruised, 3/ijas; Distilled Water Oij. Boil down to a pint, and strain.)—Formerly given in skin diseases; now fallen into disuse. Dose, 1/3iv to 1/2vj three or four times a day.

[ULMUS FULVA, Mich.—SLIPPERY ELM.
(Slippery Elm Bark, U. S.)

Sp. Char.—Leaves very scabrous above, rather unequal, and somewhat cordate at base. Buds clothed with a fulvous tomentum. Flowers in dense sub-sessile fasicles. Samara orbicular, naked on the margin. (Beck, Bot.)

This tree is sometimes called also Red Elm. It is from 20 to 40 feet high, with rugate branches. The leaves are from 4 to 6 inches long, and 2 or 3 inches broad, lanceolate oval, or obovate oblong, conspicuously acuminate, doubly serrate, the upper surface scabrous, beneath tomentose pubescent, especially along the nerves and midrib, petioles about one-third of an inch long, pubescent. Stipules pilose. Flowers on short pedicels, numerous, in dense lateral clusters. Calyx about 7 cleft; segments obtuse, clothed and ciliate, with a reddish tawny pubescence. Stamens often 7, much exerted; anthers dark-purple. Styles granular pubescent, purple. Samara orbicular, about half an inch in diameter, radiately veined, pubescent in the centre, on a slender pedicel as long as the calyx; margin smooth, cleft at apex between the styles; segments acuminate by the pubescent adnate styles, and so incurved and over-lapped as to give the margin the appearance of being entire at apex. (Darlington.)

This plant is common in the United States, growing in low grounds and along fences.

The inner bark is fibrous, and is removed from the trunk and large branches of the tree in long pieces. It is found in the shops in this form or ground into powder. It is bland and demulcent, and is used as a substitute for flaxseed and other demulcent articles. From the powder can be made an excellent poultice by mixing with the requisite quantity of hot water.

INFUSUM ULM, U. S.; Infusion of Slippery Elm Bark.—Made by macerating an ounce of Slippery Elm Bark in a pint of boiling water. Used for the ordinary purposes of a demulcent solution.

ORDER XXVIII. URTICACEÆ. EndL.—NETTLEWORTS.

Urticæ, Jusici.

Characters.—Flowers herbaceous, inconspicuous, polygamous. Calyx membranous, lobed, persistent. Stamens definite, distinct, inserted in the base of the calyx, and opposite its lobes. Ovary superior, simple. Ovule solitary, erect. Fruit a simple, indehiscent nut, naked or surrounded by the persistent calyx. Embryo straight, with fleshy siliculae; cotyledons flat; radicle superior. —Trees, shrubs, or herbs. Leaves frequently covered with asperities or stinging hairs. Stipules mostly persistent, rarely deciduous or absent.

Properties.—The order is now very circumscribed; and contains but few properties interesting to the physician. The most remarkable property of the order is the acridity (sometimes very extreme) of the liquid contained in the epidermoid gland at the base of the stinging hair. Endlichmer says that it is bicarbonate of ammonia; but this is an obvious error, as ammonia, in any known form, is incompetent to produce the violent effect ascribed to some of the East Indian Urticaceæ.

Urtication, or flagellation by a bunch of nettles (Urtica dioica), is an old method of treating palsy.²

114. Parietaria officinalis, Linn.—Common Wall-Pellitory.

Sex. Syn. Tetradrias, Monogynia. (H. ba.)

This is a common indigenous plant, which was formerly in great repute as a diuretic and lithotritic. By some practitioners it is still highly esteemed. It is used in calculous and other urinary affections, and also in dropsies. The expressed juice may be taken in doses of one or two fluidounces. Or the decoction (prepared by boiling \( \frac{3}{4} \) of the herb in a pint of water) may be substituted. The extract has also been used. On account of a nitrate which the plant contains, the extract is said to have taken fire in making it.³

¹ Enchiridion Botanicum.
³ Celsius, lib. iii. cap. 27.
ORDER XXIX. CANNABINACEÆ, Lindl.—HEMPWORTS.

Cannabinae, Endl.

Properties.—There are only two species in this family, and each of these will be separately noticed. One of these (Cannabis sativa) is remarkable for the tenacity of its fibre, and the narcotic intoxicating quality of its juices: the other (Humulus lupulus), for its bitter principle, and its fragrant oil, whose vapor is soporific.

115. CANNABIS SATIVA.—COMMON HEMP.

Sex. Syst. Dioecia, Pentandria.
(Herba et Resina. The Extract, D.)

History.—This plant was well known to the ancient Greeks and Romans, but they do not appear to have been acquainted with its narcotic properties. Dioscorides merely mentions that the expressed juice of the seeds of ἀρματις allows ears, and the same statement is made by Galen. Herodotus mentions it, and states that the Scythians cultivated it and made themselves garments of it. He also adds that they threw the seeds on red-hot stones, and used the perfumed vapour thereby obtained as a bath, which excited from them cries of exultation. This I presume refers to the intoxicating properties of its smoke. The hemp may have been, as Dr. Royle suggests, the "assuager of grief" or the nepenthes (νηπένθης) of which Homer speaks as having been given by Helen to Telemachus in the house of Menelaus. Helen is stated to have received the plant from a woman of Egyptian Thebes. It is known in India, as the "increaser of pleasure," the "exciter of desire," the "cementer of friendship," the "causer of a reeling gait," the "laughtor mover," &c.

Pliny mentions it under the name of Cannabis.

Sp. Char.—The only species.

Annual. Stem 3 to 5 or 6 feet high, erect, branched, angular. Leaves on long weak petioles, digitate, serrated, roughish. Stipules subulate. Flowers in clusters, axillary. The whole plant has a clammy feel.

Cannabis sativa, var. indica; Indian Hemp.—The plant which grows in India, and has been described by some botanists under the name of Cannabis indica or Indian Hemp does not appear to possess any specific differences from the common hemp. Roxburgh, and most other distinguished botanists have accordingly considered it identical with the Cannabis sativa of

9 In the United States of America, the denomination of Indian hemp is applied, both in the Pharmacopoeia and Dispensatory, to the Apocynum cannabinum; and it has been imported and sold in London for the real Indian hemp (Cannabis sativa, var. indica), according to the statement of Dr. Fred. J. Farre (Lond. Med. Gaz. May 5, 1843, p. 209).
10 Flora Indica, vol. iii. p. 772.
Linnaeus and Willdenow. C. indica branches from the ground up to within two feet of the top; whereas common hemp grows three or four feet before it branches. The fruit also of C. indica is smaller and rounder. I have carefully compared C. indica (both that grown in the Chelsea Garden and that contained in Dr. Wallis's Herbarium in the possession of the Linnean Society) with the C. sativa in Linnaeus's collection, and I cannot discover any essential distinction between them. The male plant appears to me to be in every respect the same. In the female plants, the flowers of C. indica were more crowded than those of common hemp.

Hab.—Persia, Caucasus, hills in the north of India. Cultivated in various other countries.

Description.—The parts employed in Asia for the purposes of intoxication, and in Europe for medicine, are the herb (leaves) and the resin.

1. Herba Cannabis sativa.—This is used in India in two forms; one called gunjah, the other bang. The hashish of the Arabs differs somewhat from gunjah.

a. Gunjah.—This is the dried hemp plant which has flowered, and from which the resin has not been removed. It is sold in the Calcutta bazaars, for smoking chiefly, in bundles of about two feet long and three inches in diameter, each containing twenty-four plants. That which I have received from Dr. O'Shaughnessy, and also found in commerce, consists of cylindrical or fusiform masses (about the size and shape of the fingers) of a grayish or greenish-brown colour, and composed of stems, leaves, and petioles pressed together. It has a faint odour and feeble bitterish taste. In commerce it is known by the name of guaza or guazah.

b. Bang, Subje, or Suilsee.—This consists of the larger leaves and capsules without the stalks. I have not met with this in commerce.

c. Hashish or Hashish.—This, according to Steeze,\(^1\) consists of the tops and tender parts of the plant collected after inflorescence.

2. Resina Cannabis sativa.—The concreted resinous exudation from the leaves, slender stems, and flowers, is called Churrus. The mode of collecting it is somewhat analogous to that adopted in Crete for the collection of ladanum. In central India and the Saugar territory, and in Nipal, Churrus is collected during the hot season in the following singular manner: Men clad in leathern dresses run through the hemp fields, brushing through the plant with all possible violence; the soft resin adheres to the leather, and is subsequently scraped off and kneaded into balls, which sell from five to six rupees the seer. A still finer kind—the Momeca or waxen Churrus—is collected by the hand in Nipal, and sells for nearly double the price of the ordinary kind. In Nipal, Dr. M'Kinnon informs me, the leathern attire is dispensed with, and the resin is gathered on the skin of the naked coolies. In Persia, it is stated by Mirza Abdul Razee that the Churrus is prepared by pressing the resinous plant on coarse cloths, and then scraping it from these and melting it in a pot with a little warm water. He considers the Churrus of Herat as the best and most powerful of all the varieties of the drug.\(^3\) I have a specimen of spurious Churrus.

Churrus, such as I have received it from Dr. O'Shaughnessy, is in masses having the shape and size of a hen's egg, or of a small lemon, and formed by the adhesion of superimposed elongated pieces. It has a dull grayish-brown colour, and not much odour. It consists of resinous and various foreign matters (fragments of flowers, leaves, seeds, &c.)

3. Fructus Cannabis sativa.—The fruits, called usually hempseed (semen can-

---

1. This agrees with a remark in the Hortus Cliffortianus: "Quod mas in Horto Malabarico exhibitus nostra sit planta nullum dubium detur; semina autem parum recepit folis ternatis, tamen et ejusmodi plantas in sole macro apud nos observavimus non infrequenter."

nabis), are small, ash-coloured, shining, nut-like or seed-like bodies. They are demulcent and oleaginous, but not narcotic. They are employed for feeding cage-birds. They are said by Burnett to possess the singular property of changing the colour of the plumage of bullfinches and goldfinches from red and yellow to black, if the birds are fed on the seeds for too long a time or in too large a quantity (?).

**Composition.**—The leaves of common hemp have been submitted to analysis by Tscheepe, by Schlesinger, and by Bohlig. The results of the two former of these are as follows:

Leaves of Cannabis sativa.

Leaves dried at 200° F ............................................. 100.000

Bohlig found a great agreement between the constituents of common hemp and those of the stinging nettle (Urtica dioica).

Dr. Kane has made an ultimate analysis of the leaves and herb of hemp as well as of their ashes; but the results have no medical interest.

Hempseeds have been analyzed by Buchholz, who obtained—fixed oil 19.1, resin 1.6, sugar with extractive 1.6, gummy extract 9.0, soluble albumen 24.7, woody fibre 5.0, husk 38.3, loss 0.7 = 100.0.

1. **Volatile Oil of Hemp.**—This has hitherto been procured in such small quantities that its properties are but imperfectly known. When the dried plant is distilled with a large quantity of water, traces of the oil pass over, and the distilled liquor has the odour of the plant.

2. **Cannabis; Resin of Hemp.**—This appears to be the active principle of hemp. It is a soft, neutral resin, soluble in alcohol and in ether, and separable, by the addition of water, from its alcoholic solution, in the form of a white precipitate. It has a warm, bitterish, acrid, somewhat balsamic taste, and a fragrant odour, especially when heated. Messrs. T. and H. Smith say that it very much resembles jalap resin or jalapine, except in remaining soft even after continued drying, and in its odour and taste.

3. **Fixed Oil of Hempseed; Hempseed Oil; Oleum Cannabis.**—This is a drying oil obtained in Russia, by expression, from hempseeds, which yield about 25 per cent. of it. At first it is greenish-yellow, subsequently yellow. It has an acrid odour, but a mild taste. Its sp. gr. is 0.9276 at 52°. It dissolves readily in boiling alcohol, in 30 parts of cold alcohol. At —17° F it freezes. It is used in the preparation of a soft soap, in paint, and in lamps for the purpose of illumination; but it is apt to clog the wick by the formation of a viscid adherent varnish. When boiled it makes a good varnish.

**Physiological Effects.**—A general statement of the effects of Indian hemp has already been made (see ante, p. 236). Its action as a neurotic is essentially that of a cerebro-spinal (see ante, p. 235). It operates as a phrenic in moderate doses producing exhilaration, inebriation with phantasms, and more or less confusion of intellect, followed by sleep; in large doses causing stupor. Hence it may be called an exhilarant, inebriant, phantasmatic, hypnotic or soporific, and stupefiant or narcotic.

On Orientals, the inebriation or delirium produced by it is usually of an agreeable or cheerful character, exciting the individual to laugh, dance, and sing, and to commit various extravagancies—acting as an aphrodisiac, and augmenting the appetite for food. In some, it occasions a kind of reverie. It renders others excitable and quarrelsome, and disposes to acts of violence.

6 Quoted by L. Gmelin, Handb. de Chemie.
8 It has been stated that the men who attempted the assassination of Lord Cornwallis in India were intoxicated by Indian hemp (Thornton, History of the British Empire in India, vol. ii. p. 486, 1848.)
The singular form of insanity said to be brought on by it has already (see vol. i. p. 237) been noticed.

It acts as an anæsthetic (see vol. i. p. 238). It relieves pain, and is, therefore, employed as an anodyne or paregoric. Moreover, Mr. Donovan¹ found that under its influence his sense of touch and feeling gradually became obtuse, until at length he lost all feeling unless he pinched himself severely; and Dr. Christison² states he felt a pleasant numbness of his limbs after its use.

Its influence as a cinetie (see vol. i. p. 240) or agent affecting the action of the muscles, is remarkable. It relieves spasm, and is, therefore, frequently used as an antispasmodic. On Orientals large doses produce a cataleptic condition (in which the muscles are moderately contracted, but flexible and pliant, and the limbs retain any position or attitude in which they may be placed).

The following illustrative cases are taken from Dr. O'Shaughnessy's paper on Indian hemp:

At two P. M. a grain of the resin of hemp was given to a rheumatic patient. At four P. M. he was very talkative, sang, called loudly for an extra supply of food, and declared himself in perfect health. At six P. M. he was asleep. At eight P. M. he was found insensible, but breathing with perfect regularity, his pulse and skin natural, and the pupils freely contractile on the approach of light. Happening by chance to lift up the patient's arm, the "professional reader will judge of my astonishment," observes Dr. O'Shaughnessy, "when I found that it remained in the posture in which I placed it. It required but a very brief examination of the limbs to find that the patient had by the influence of this narcotic been thrown into that strange and most extraordinary of all nervous conditions, into that state which so few have seen, and the existence of which so many still discredit—the genuine catalepsy of the nosologist. We raised him to a sitting posture, and placed his arms and limbs in every imaginable attitude. A waxen figure could not be more pliant or more stationary in each position, no matter how contrary to the natural influence of gravity on the part. To all impressions he was meanwhile almost insensible." He continued in this state till one A. M., when consciousness and voluntary motion quickly returned.

Another patient who had taken the same dose fell asleep, but was aroused by the noise in the ward. He seemed vastly amused at the strange aspects of the statue-like attitudes in which the first patient had been placed. "On a sudden he uttered a loud peal of laughter, and exclaimed that four spirits were springing with his bed into the air. In vain we attempted to pacify him; his laughter became momentarily more and more uncontrollable. We now observed that the limbs were rather rigid, and in a few minutes more his arms and legs could be bent, and would remain in any desired position. He was moved to a separate room, where he soon became tranquil, his limbs in less than an hour gained their natural condition, and in two hours he expressed himself perfectly well and excessively hungry."

On Europeans I have never heard of a cataleptic state being produced by this drug. In a case of tetanus under my care in the London Hospital, and which was carefully watched by Dr. O'Shaughnessy and myself, the resinous extract of Indian Hemp was given in increasing doses up to twenty grains. It caused stupor and cessation of spasm; but no perfect cataleptic state. The only tendency to this condition which was observed was when the arm of the patient was lifted and then cautiously let go; it fell slowly and gradually, not quickly, as it would have done under ordinary conditions: the patient was at this time quite insensible.

By internal use it acts as a mydriatic (see vol. i. p. 246), causing preternatural dilatation of the pupil. But Dr. Lawrie³ states that when applied around the eye it does not cause dilatation of the pupil.

Indian hemp does not appear much to affect the secretions. It neither excites nausea nor lessens the appetite. It neither causes dryness of the tongue nor constipation of the bowels. It does not appear to check or otherwise affect the bronchial secretions. I am disposed to think that it is somewhat sudorific. Drs. Ballard and Garrod⁴ state that in large doses it communicates an odour to the urine like that evolved when the tincture is mixed with water, and in part like that of the Tonquin bean.

Compared with opium, Indian hemp differs in its operation on the system in several remarkable circumstancenses: as by its inebriating, phantasmatic, and aphrodisiac effects; by its causing catalepsy and dilatation of pupil; and by its not

¹ Dublin Journal of Medical Science, Jan. 1845.
³ Dispensatory
⁴ Elements of Materia Medica.

VOL. II.—22
causing nausea, loss of appetite, dry tongue, constipation, or diminution of the secretions.

Dr. Hooke, in his account of Indian hemp (Bangue) read to the Royal Society, Dec. 18, 1680, notices the various odd tricks shown by persons while in the ecstasy caused by this plant; and adds that, when this condition subsides, the patient finds himself mightily refreshed and exceedingly hungry.

The general effects of Indian hemp on man, as stated by Dr. O'Shaughnessy, from his own observations, are alleviation of pain (mostly), remarkable increase of appetite, unequivocal sphondiasia, and great mental cheerfulness. Its more violent effects were delirium of a peculiar kind, and a cataleptic state.

Its effects on animals were analogous: he gave ten grains of Nipanese Churrus dissolved in spirit to a middling-sized dog: "In half an hour he became stupid and sleepy, dozing at intervals, starting up, wagging his tail as if extremely contented; he ate some food greedily, on being called to he staggered to and fro, and his face assumed a look of utter and helpless drunkenness. These symptoms lasted about two hours, and then gradually passed away; in six hours he was perfectly well and lively."

It would appear that Indian hemp acts more powerfully in India than in Europe. My experiments (detailed in the 2d edition of this work, pp. 1097–8) fully bear out this statement. Dr. O'Shaughnessy, when in England, satisfied himself of the difference of the effect of Indian hemp in this country and in Bengal; and he observes,1 that while in India he had seen marked effects from half a grain of the extract, or even less, and had been accustomed to consider one grain and a half a large dose, in England he had given ten or twelve or more grains to produce the desired effect.

Uses.—Indian hemp is chiefly employed as a medicine, for its hypnotic, anodyne, and antispasmodic properties; occasionally, also, for its mental influence (i.e., as a phrenic and nervine). Compared with opium, it is less certain than the latter agent; over which, however, it has several advantages. Thus it does not constipate the bowels, lessen the appetite or create nausea, produce dryness of the tongue, or check the pulmonary secretion, as opium is well known to do. Moreover, in some patients in whom opium causes headache, and various distressing feelings, Indian hemp occasionally acts without any of these inconveniences; but I have heard others object to its continuance on the ground of its very unpleasant effects.

As a hypnotic, I have used it with advantage in spirit-drinkers, and have succeeded in one or two cases in producing sleep with it where large doses of morphia had failed. In some hysterical patients, and in cases of chorea, I have occasionally employed it to induce sleep, where the use of opium was from some cause objectionable. Dr. Clendinning2 speaks favourably of its soporific influence in pulmonary affections and low fever. It has the great advantage over opium of neither repressing the secretions nor lessening the appetite for food.

As an anodyne, it is, I think, in general, decidedly inferior to opium; but there are occasions where its use is to be preferred to the latter agent. In acute and subacute rheumatism, in gout, and in neuralgia, it frequently alleviates the pain.

As an antispasmodic, it has been employed in tetanus, hydrophobia, malignant cholera, chorea, and infantile convulsions. In the cases of tetanus (both traumatic and idiopathie) and of hydrophobia which I have seen treated with it, it completely failed to give permanent relief. In one case of traumatic tetanus, it alleviated the pain and spasms, but the patient notwithstanding died. In a case under the care of Professor Miller,3 it was given, and the patient recovered. It has failed, however, in the hands of Mr. Potter4 and others. And in a case of idiopathic tetanus in Guy's Hospital, under the care of Dr. Babington,5 it proved useless. In chorea, I have found it serviceable, sometimes as an antispasmodic, at others as a hypnotic; and the same may be said of its use in hysteria.

As a phrenic or medicinal agent affecting the mental functions, Indian hemp has also been employed. Dr. Clendinning speaks favourably of its use as a nervine stimulant, in removing languor and anxiety, and raising the pulse and spirits; and

4 *Lancet*, vol. i. p. 98, Jan. 11, 1845.
Dr. Conolly thinks that it may be useful in some chronic forms of mania. Dr. Sutherland has not obtained any good effect from it.

ADMINISTRATION.—In England, Indian hemp is usually administered in the form of resinous or alcoholic extract and of tincture.

1. EXTRACTUM CANNABIS INDICE ALCOHOLICUM; Resinous or Alcoholic Extract of Indian Hemp.—This is the preparation usually sold in the shops under the name of resin of Indian hemp or cannabis (see ante, p. 336). Dr. O'Shaughnessy directs it to be prepared by boiling the rich adhesive tops of the dried gunjah in rectified spirits until all the resin is dissolved. "The tincture thus obtained is evaporated to dryness in a vessel placed over a pot of boiling water. The extract softens at a gentle heat, and can be made into pills without any addition." Mr. Robertson, of Calcutta, prepared it by a kind of percolation process; the vapour of alcohol being transmitted through the dry herb. At first a thin tarry matter containing much resin, latterly a brown liquor containing little resin but much extractive passed over. At this point, water was substituted for the spirit in the still, and as much as possible of the spirit retained by the plant thus expelled from it. Part of the alcohol was removed from the fluid by distillation; but the rest was dissipated by evaporation at a temperature not exceeding 150° F. From 1 cwt. of the plant about 8 lbs. of extract were obtained at one operation, which was so slowly conducted as in all its stages to last a fortnight.

The following is the process given by the Messrs. Smith, of Edinburgh, for the preparation of this extract: Digest bruised gunjah in successive quantities of warm water till the expressed water comes away colourless; and again for two days, at a moderate heat, in a solution of carbonated soda, in the proportion of one part of the salt to two of gunjah. Colouring matter, chlorophyll, and inert concrete oil being thus removed, express and wash the residuum, dry it, and exhaust it by percolation with rectified spirit. Agitate with the tincture, milk of lime containing an ounce of lime for every pound of gunjah, and, after filtration, throw down the excess of lime by a little sulphuric acid. Agitate with the filtered liquor a little animal charcoal, which is afterwards to be removed by filtration. Distil off most of the spirit, add to the residual tincture twice its weight of water in a porcelain basin, and let the remaining spirit evaporate gradually. Lastly, wash the resin with fresh water till it comes away neither acid nor bitter, and dry the resin in thin layers. This resin contains the peculiar taste and odour of the gunjah. A temperature of 180° F. acting for eight hours on thin layers of it exposed to the air does not impair its activity. 100 lbs. of dry gunjah yield about 6 or 7 lbs. of this extract.

The Dublin College directs the Extractum Cannabis Indice purificatum to be prepared as follows:—

Take of Extract of Indian Hemp of Commerce 3j; Rectified Spirit 3j iv. Dissolve the extract in the spirit, and when the dregs have subsided, decant the clear liquid, and evaporate, by means of a water-bath, to the consistence of a soft extract.

The dose of the alcoholic extract of Indian hemp is usually from gr. j to grs. v. I have usually found one grain of the extract kept in the London shops to act as a narcotic. The Messrs. Smith state that two-thirds of a grain of the pure resin produced on themselves and others powerful narcotic effects. In a case of tetanus under my care in the London Hospital, the dose of the extract (supplied by Dr. O'Shaughnessy, who watched the case with me) was gradually increased to grs. xx. It may

1 See also Moreau, Du Haschisch et de l'Altération Mentale, Études Psychologiques, Paris, 1815.
be administered in the form of pill; or better by diffusion through an emulsion (prepared by rubbing the extract with olive oil, in a warm mortar, and gradually adding mucilage, and afterwards water), or by solution in rectified spirit, and dropping the tincture into water immediately before its administration.

2. TINCTURA CANNABIS INDICA, D.; Tincture of Indian Hemp.—(Purified Extract of Indian Hemp 38s; Rectified Spirit 6s. Dissolve the extract in the spirit, D.)

—These are the proportions directed to be used by Dr. O'Shaughnessy; but, probably by a typographical error, he has ordered proof spirit instead of rectified spirit. Dose from m. x to f. j. Dr. O'Shaughnessy gives in tetanus 3j every half hour, until the paroxysms cease, or catalepsy is induced; in cholera, ten drops every half hour. It may be administered in an emulsion or mucilaginous mixture, or in water sweetened with sugar. It should be swallowed soon after it has been added to the aqueous liquid, as the resin precipitates, and is apt to adhere to the side of the vessel.

Other Preparations of Indian Hemp.—By the Asiatics, Egyptians, and others who employ Indian hemp for the purposes of intoxication, various preparations of this drug are in use. In some of these the plant itself is employed, either rubbed up with water and made into a draught or formed into an electuary. But a favourite mode of using it is to extract the active principle by some fatty matter (generally butter or oil), by which an oleaginous solution or fatty extract is obtained. For this purpose the hemp is boiled in butter or oil, with a little water, usually until the water is boiled away. It is said that the fatty extract thus obtained will preserve its intoxicating powers for years. It is usually mixed up with other ingredients, and taken in the form of an electuary, confection, or paste. The majoon used at Calcutta,1 the mpouchari employed at Cairo,2 and the dawamec of the Arabs,3 are preparations of this kind. Lastly, hemp is also used for smoking in pipes.

Antidotes.—In a case of poisoning by Indian hemp the treatment should be the same as that for poisoning by opium (which see).

116. HUMULUS LUPULUS, Linn.—THE COMMON HOP.

Sex. Syst. Dicoty., Pentandria.

(Amentum, L.—Catkin, E.—The dried strobiles. Lupula; the yellow powder separated from the strobiles by rubbing and sifting, D.)

History.—This plant is probably the Lupus salicarius of Pliny.4 Its culture was introduced into this country from Flanders, in the reign of Henry VIII.5

Botany. Gen. Char.—Dioecious. MALES:—Calyx 5-partite. Stamens 5. FEMALES:—Strobiles consisting of large, persistent, concave scales [bracts], having a single flower in the axilla of each. Ovary 1. Styles 2. Seed 1, with an arillus. Embryo spirally contorted (Bot. Gall.).

Sp. Char.—The only species.

Perennial. Stems annual, long, weak, and climbing, scabrous. Leaves petiolate, 3- to 5-lobed, serrated, veiny, rough. Flowers greenish yellow.

Hab.—Thickets and hedges in many parts of Europe. Indigenous [?]. Flowers in July.

Cultivation.—The female plant is cultivated in several counties in England, especially Kent, Sussex, Surrey, Worcestershire, and Herefordshire. The third year after planting it generally comes into full bearing. Stacking or setting the poles is performed in April or May. The gathering or picking takes place in September. The cones are dried in kilns, and are then packed in hempen sacks, called bags or pockets. This operation is called bagging.6

Description.—The aggregate fruits of the Humulus Lupulus are strobiles or catkins (strobili seu amenta lupuli), in commerce termed hops. They consist of scales, nuts, and lupulinic glands or grains. The scales are the enlarged and persistent bracts, which enclose the nuts: they are ovate, membranous, and at their

5 Loudon's Encyclopaedia of Agriculture.
base glandular. The nuts (achtenia) are small, hard, nearly globular, and covered with aromatic, superficial, globose glands. The lupulinic glands or grains (commonly termed yellow powder or lupulin) are the most important parts of the strobiles. By thrashing, rubbing, and sifting, Dr. Ives procured 14 ounces from six pounds of hops; and he therefore concluded that dry hops would yield about a sixth part of their weight of these grains. They are usually intermixed with sand. They are rounded, of a cellular texture, golden yellow, and somewhat transparent. They are sessile, or nearly so. The common centre, around which the cells are arranged, has been called the hilum. By drying they lose their spherical form. Placed in water they give out an immense number of minute globules.

Humulus Lupulus. Under other circumstances they become ruptured, and allow an inner envelop to escape. According to Turpin, they consist of two vesicles, one enclosing the other. The inner one contains globules, an aromatic oil, and a gas. He also states that, in the bubbles of the disengaged gas, an immense number of crystals are formed.

**Composition.**—Payen, Chevallier, and Pelletan analyzed the scales and lupulinic grains. Dr. Ives also examined the latter.

1 *Journal of Science*, vol. xi. p. 305.
1. **Volatile Oil of Hops.**—Resides in the lupulinic grains. Obtained by submitting these, or hops which contain them, to distillation with water. Its colour is yellowish, its odour that of hops, its taste acrid. It is soluble in water, but still more so in alcohol and ether. Its sp. gr. is 0.910. By keeping, it becomes refined. It is said to act on the system as a narcotic. The water which comes over, in distillation, with the oil, contains acetate of ammonia, and blackens silver; from which circumstance the presence of sulphur is inferred.

2. **Bitter Principle of Hops; Lupulite.**—It is procured by treating the aqueous extract of the lupulinic grains, united with a little lime, with alcohol. The alcoholic tincture is to be evaporated to dryness, the residue treated with water, and the solution evaporated. The residue, when washed with ether, is lupulite. It is uncrystallizable, yellowish white, very bitter, soluble in 20 parts of water, very soluble in alcohol, and slightly so in ether. The aqueous solution froths by agitation; it forms no precipitate with either tincture of muscals or acetate of lead. Lupulite contains no nitrogen. It is devoid of the narcotic property of the oil. In small doses it is said to have caused loss of appetite and diminished digestive power; but a repetition of the experiment is very desirable.

3. **Tannic Acid; Tannin.**—In the manufacture of beer, this principle serves to precipitate the nitrogenized or albuminous matter of the barley, and, therefore, for clarification.

4. **Resin.**—Is of a golden yellow colour, and becomes orange-yellow by exposure to the air. It is soluble in both alcohol and ether. It appears to be the oil changed into resin, partly by oxidizement.

**Chemical Characteristics.**—A decoction of hops reddens litmus, owing to the presence of free acid. Sesquichloride of iron strikes an olive green colour (tannate of iron). A solution of gelatin renders the filtered decoction turbid (tannate of gelatin). Chloride of barium occasions with it a white precipitate (sulphate of baryta). Oxalate of ammonia also causes a white precipitate (oxalate of lime).

**Physiological Effects.**—The odorous emanations (vapour of the volatile oil) of hops possess narcotic properties. Hence a pillow of these cones promotes sleep, as I have several times witnessed. Moreover, we are told that stupor has occasionally been induced in persons who have remained for a considerable time in hop warehouses.

The lupulinic grains are aromatic and tonic. They appear also to possess soothing, tranquillizing, and, in a slight degree, sedative and soporific properties. But the existence of any narcotic quality has been strongly denied by Dr. Bignsey, Magendie, and others. "I have tried, at different times," says Magendie, "both the lupulinic lupulinic grains) in substance, and its different preparations, on animals, but I have never observed that it is a narcotic, although this property is one which is most strikingly displayed in experiments on animals." Dr. Maton found that it allayed pain, produced sleep, and reduced the frequency of the pulse from 96 to 60 in twenty-four hours.

Both infusion and tincture of hops are mild but agreeable aromatic tonics. They sometimes prove diuretic, or, when the skin is kept warm, sudorific. Their sedative, soporific, and anodyne properties are very uncertain.

**Uses.**—A pillow of hops (cerecatalae pulvinus, pulvinar lupuli) is occasionally employed in mania, and other cases in which inquietude and restlessness prevail, and in which the use of opium is considered objectionable. In hop countries it is a popular remedy for want of sleep. The benefit said to have been obtained from it by George III., for whom it was prescribed by Dr. Willis, in 1787, brought it into more general use.

Hops are given internally to relieve restlessness consequent upon exhaustion and fatigue, and to induce sleep in the watchfulness of mania and of other maladies; to calm nervous irritation; and to relieve pain in gout, arthritic rheumatism, and after accouchement. Though they sometimes produce the desired effect, they frequently fail to give relief. Dr. Maton used it, with good effect, as an anodyne in rheumatism.

As a tonic, it is applicable in dyspepsia, cachectic conditions of the system, or any other maladies characterized by debility.

Hops have been applied, topically, in the form of fomentation or poultice, as a

---

resolvent or discurient, in painful swellings and tumours. Freake employed an ointment, composed of lard and the powder of the hop, as an anodyne application to cancerous sores.¹

But the principal consumption of hops is in the manufacture of beer and ale, to which they communicate a pleasant, bitter, and aromatic flavour, and tonic properties; while, by their chemical influence, they check the aceturous fermentation. Part of the soporific quality of beer and ale is usually ascribed to the hops used in the manufacture of these beverages.

Administration.—The best preparation of hops, for internal use, is the yellow powder (lupulinic grains or lupulin). The infusion and tincture are less eligible modes of exhibition. The extract is still more objectionable. Well-hopped-beer is a convenient mode of administering hops, when fermented liquors are not contraindicated (see ante, p. 118).

1. INFUSUM LUPULI, L.; Infusion of Hops.—(Hops ½vj; Boiling Distilled Water Oj [Hops §ss; Boiling Water Oj, U. S.].) Macerate for four [two, U. S.] hours in a vessel lightly covered, and strain.)—Dose, f½j to f¾j.

2. TINCTURA LUPULI, L. [U. S. ]; Tincture of Hops.—(Hops ¾vj [3v, U. S.]; Proof Spirit Oj. Macerate for seven days, and strain.)—Dose, f½ss to f¾j.

3. EXTRACTUM LUPULI, L. E.; Extractum Humuli, D.; Extract of Hops.—(Hops ½bjs [½bj, E.]; Boiling Distilled Water Cong. ij [Cong. j, E.]. Macerate for twenty-four hours, then boil down to a gallon [Oiv, E.], and strain the liquor while hot; lastly, evaporate [in the vapour bath, E.] to a proper consistence. The directions of the Dublin College are nearly the same as those of the Edinburgh College.)—Dose, grs. v to ½j. Whatever virtue this preparation possesses is owing to the bitter principle or lupulite.

4. LUPULINA; Yellow Powder; Lupulinic Grains or Glands.—(Separated from the strobles by rubbing and sifting.)—Dose, grs. vj to grs. xij, taken in the form of powder or pills.

5. TINCTURA LUPULINE, D.; Tinctura Lupuli, E.—(Lupulin ¾v; Rectified Spirit Oj. Macerate for fourteen days, strain, express, and filter, D.—Take any convenient quantity of Hops, recently dried; separate by friction and sifting the yellowish-brown powder attached to the scales. Then take of this powder ¾v [¾v, U. S.]; and of Rectified Spirit Oj; and prepare the tincture by percolation or digestion, as directed for tincture of capiscum. Ph. Ed.)—Dose, f½ss to f¾j.

ORDER XXX. MORACEÆ.

Morus, Endlicher.

Characters.—Flowers unisexual. Males:—Calyx 0, or 3—4-parted. Stamens 3—4, inserted into the base of the calyx and opposite its segments. Females:—Calyx 0, or 4—5-parted. Ovary 1-celled, rarely 2-celled. Ovules solitary, pendulous, or amphitropous, with the stamens uppermost. Fruit small nuts or uricles, 1-seeded, inclosed within the succulent receptacle, or collected in a fleshy head formed by the consolidated succulent calyx. Seed solitary, with a thin brittle testa; embryo lying in fleshy albumen, hooked, with the radicle long, superior, folded down towards the cotyledons.—Trees or shrubs, with a milky juice. Leaves furnished with stipules.

Properties.—Various. The milky juice of some species is bland and potable; of others acid and poisonous. In India, Ficus elastica yields caoutchouc. Macura tinctoria furnishes the dyewood called Fustic, whose colouring principle is termed morine.

117. MORUS NIGRA, Linn.—THE COMMON MULBERRY.

(Fructus Succus, L.)

History.—The mulberry (μοῦρα) is mentioned by Hippocrates
d—“Mora calcia-
ciunt et humectant ac alvo secedunt,” says the Father of Physic. Dioscorides also
speaks of the mulberry.

Botany.—Gen. Char.—Monoecious. Catkins unisexual. Calyx 4-lobed; the
lobes concave. Stamens 4, alternate with the segments of the calyx. Ovary free.
Stigmas 2. Seeds 1-2, covered by the pulpy calyx (Bot. Gall.).

Sp. Char.—Leaves cordate, ovate, lobed, or unequally dentate; rough and thickish.
Fruit dark purple (Bot. Gall.).

Fig. 291.

Morus Nigra.

A small tree, with rugged bark. Flowers greenish. “Fruit, consisting of the female flow-
ers, become fleshy and grown together, inclining a dry membranous pericarp.” (Lindley.)

Hab.—Native of Persia and China. Cultivated for its fruit. Flowers in May.

Description.—The fruit is usually called a
berry (bacca mori nigrae), but is, in fact, that
kind called by botanists a sorosis. Its odour is
peculiar and agreeable; its taste is peculiar, plea-
sant, acidulous, and sweet. The juice is dark
violet red.

Composition.—The fruit has not been ana-
lyzed. Its principal constituents are—violet-red
colouring matter, tartaric acid, sugar, and woody
fibre. The root has been analyzed by Wacken-
roder.3

Physiological Effects.—Mulberries are ali-
mentary in a slight degree; they allay thirst, diminish febrile heat, and, in large
quantities, prove laxative.

Use.—They are employed as an agreeable aliment, and are well adapted to check
preternatural heat and relieve thirst in fevers, but are objectionable when a tendency
to diarrhoea exists. They owe their retention in the Pharmacopoeia to their colour and
flavour.

SYRUPUS MORI, L.; Syrup of Mulberry.—(Juice of Mulberries, strained, Oj; Sugar fiijss; Rectified Spirit f3ijss. Dissolve the sugar in the mulberry juice
with a gentle heat, and set aside for twenty-four hours; then remove the scum, and
pour off the clear liquor from the dregs if there are any. Lastly, add the spirit.)—
Used as a colouring and flavouring substance. Its acidity prevents its being used
with alkalies, earths, or their carbonates.

118. FICUS CARICA, Linn.—THE COMMON FIG.

(Fructus preparatus, L.—Fici: the dried fruit, E. D.)

History.—In the Old Testament we are informed that Hezekiah (who lived
600 years before Christ) used figs as a topical application to a boil.4 The fig-

1 De victus ratione, lib. ii. p. 360, ed. Faw.
2 Gmelin's Handb. d. Chem. ii. 1324.
3 Lib. i. cap. 150.
4 Isaiah, xxxviii. 21.
tree is the ruxum of Dioscorides; the Ficus of Pliny.

**BOTANY. Gen. Char.—Monoeious.** Flowers numerous, pedicellated, inclosed within a fleshy receptacle, which is umbilicated, and nearly closed at the apex, hollow within. **Calyx** 3—5-lobed: lobes acuminate. Male-flowers near the umbilicus. **Stamens** 3—5. **Ovary** free (Desf.); semi-adenate (Gaertn.). **Style** 1. **Stigmas** 2. Drupe or utricle 1-seeded, sunk into the pulpy receptacle. **Coat** of the nut fragile, crustaceous (Bot. Gall.).

**Sp. Char.**—Leaves cordate, palmate; scabrous above, pubescent beneath (Bot. Gall.).—A small tree. Flowers in June. **Receptacle** green. At the base of each receptacle are two or three bracteal scales.

**Hab.**—Native of Asia and South of Europe.

**Description.**—Figs (fici seu carice) constitute that kind of collective fruit called, by Mirbel, a syconus. They consist of fleshy, hollow, pyriform receptacles, within which are numerous, small, seed-like bodies (achenia, Lindley; utricles, Auctor). In the unripe state they contain an acrid and bitter juice, but which, when they are ripe, is replaced by sugar. Ripe figs are dried in the sun or in ovens, and are afterwards packed in drums and baskets, in which they are imported. As met with in the shops, they are more or less compressed, are covered with a whitish, saccharine efflorescence, have a brownish or yellowish colour, and are somewhat translucent. They have a peculiar and agreeable odour, and contain a sweet, viscid pulp, in which are the achenia. Turkey or Smyrna figs are the largest, most juicy, and sweetest; hence they are sometimes termed fat figs (caricae pingues): they are distinguished into pulled and flat. Of 20,406 cwt.s. of figs, imported in 1830, no less than 18,801 came from Turkey (Parliament Return).

**Composition.**—Bley analyzed Smyrna figs, and obtained the following results: Sugar of figs 62.5, fatty matter 0.9, extractive with chloride of calcium 0.4, gum with phosphoric acid 5.2, woody fibre and seeds [achenia] 15.0, and water 16.0 = 100.0.

**Physiological Effects.**—Figs are nutritive, emollient, demulcent, and laxative. In the fresh state they are both agreeable and wholesome: when dried, as we receive them, they readily disorder the stomach and bowels, and occasion flatulence, griping, and mild diarrhoea.

**Uses.**—In those countries where they are plentiful, figs are used as food. Here they are chiefly employed as a dessert. Internally they are given in the form of demulcent decoctions (as the Decoctum Hordei compositum, L. D.) in pulmonary and nephritic affections. As laxatives they are sometimes taken with the food to relieve habitual constipation, and enter into the composition of Confectio Senna, L. (Electuarium Senna, E.). Roasted or boiled, and split open, they are employed as supplicative cataplasms in gum-boil, &c.

3 Hist. Nat. lib. xxiii. cap. 63.
119. DORSTENIA CONTRAJERVA, Linn.; and
D. BRASILIENSIS, Lam.

Sex. Syst. Tetrandria, Monogynia.

(Radix.)

History.—The earliest notice of this plant is that by Monardes, who states that the word contrajerva is the Indo-Spanish term for alexipharmic or counter-poison. In 1581, Clusius received from Sir Francis Drake a root, which he called, after the donor, drajiena radix, and which has been supposed to be contrajerva root.

Botany. Gen. Char.—Monoeccious. Flowers arranged upon a fleshy receptacle, usually flat and expanded, and extremely variable in form: males on the surface of the receptacle, 2-lobed, fleshy, diandrous; females immersed in the receptacle, also 2-lobed in most species. Ovary 1—2-celled, with a single suspended ovule in each cell. Style 1. Stigma 2-lobed. Achene lenticular, imbedded in the fleshy receptacle, from which they are projected with elasticity when ripe.—Dwarf herbaceous plants with scaly rhizomata (Lindley). Species.—1. D. Contrajerва, Linn.—Cauliscent; stem covered with spreading green scaly stipules. Leaves palmate; the lobes lanceolate, acuminate, coarsely serrated and gashed, occasionally almost pinnatifid. Receptacle on a very long stalk, quadrangular, wavy, or plated (Lindley). A native of New Spain, Mexico, Peru, Tobago, St. Vincent's (Willd.). The root of this is not met with in commerce.

2. D. brasiliensis, Lam.—A native of Jamaica, Brazil, and Trinidad. This yields the contrajerva root usually met with in the shops.

Description.—The contrajerva root (radix contrajerva) usually found in the shops, is imported from the Brazils. It consists of an ovoid or oblong rootstock, terminating inferiorly in one or several long, tapering, more or less curved root-fibres. From the sides of the rootstock also arise numerous slender fibres. Externally the colour is yellowish-brown. The odour of the root is peculiar, but aromatic. The taste is warm, bitterish, slightly acrid.

I have also found another kind of contrajerva root in the shops. The root-stalk is smaller, cylindrical, blackish-brown, with fewer fibres. The receptacle and leaves are attached; the latter are reniform. Is this the drajiena radix of Clusius?

Composition.—The root has not been analyzed. It contains, according to Geiger, volatile oil, bitter extractive, and starch. To which may be added resin, free acid, and woody fibre.

Physiological Effects.—Stimulant, tonic, and diaphoretic. Its operation is very analogous to that of serpentine root, between which and the rhizome of the sweet flag it deserves to be arranged. The root of the Dorstenia brasiliensis often proves emetic.

---

1 Clusius, Exoticorum, lib. x. p. 311.
2 Hand. d Pharm.
3 Ibid. p. 83.
4 De Candolle, Essai sur les Propriétés Méd.
USES.—Obsolete, or nearly so. It has been employed in fevers of a low type, and in other diseases requiring a mild, stimulant, and diaphoretic treatment.

ADMINISTRATION.—The dose of the root in powder is 3j or 3ss. The infusion (prepared by digesting from 3v in f3v of boiling water) may be given in doses of f3j or f3ij. The "puleus contrajervae compositus" (composed of powdered contrayerva root 3v, and prepared shells 1b3ss) is no longer official.

ORDER XXXI. ARTOCARPACEAE, Lindley.

Artocarpace, R. Brown; Endl.

CHARACTERS.—Flowers unisexual, in dense heads. **Males**.—Calyx 0, or consisting of 2—4 sepals. Stamens opposite the sepals. **Females**.—Flowers arranged over a fleshy receptacle. Calyx tubular, with a 2—4-cleft or entire limb. **Ovary** free, l-celled. **Ovules** suspended. Fruit surrounded by a dry or fleshy receptacle, or composed of consolidated fleshy calyces, within which lies a multitude of nuts. Seeds erect, parietal or pendulous. **Embryo** more or less albuminous, straight, with the radicle directed towards the vertex of the ovary. **Trees** or shrubs, with a milky juice. **Leaves** alternate. **Stipules** large, convolute.

PROPERTIES.—The milky juice is variable in quality: in some species being poisonous, in some edible, in others neither. It usually, if not invariably, contains caoutchouc. —**The Artocarpus incisa**, or Bread fruit tree, and the *A. integrifolia* or *Jakt fruit*, deserve notice on account of their important alimentary uses. *Artocarpus incisa* is a native of the islands of the Pacific and of the Moluccas. Its fruit is to the inhabitants of Polynesia what corn is to the people of the other parts of the world. *Artocarpus integrifolia* is cultivated throughout southern India, and all the warmer parts of Asia. Its fruit forms a very considerable article of food in Ceylon.1

120. Antiaris toxicaria, Leschianilt.—Antsjar or Upas.

This is the celebrated Antsjar or Upas poison tree of Java, rendered notorious principally in consequence of certain gross falsehoods concerning it, about the year 1780, by a person of the name of Foersch, said to have been a surgeon in the service of the Dutch East India Company. Malefactors, says this person, when they receive sentence of death, are offered the chance of life, if they will go to the Upas-tree for a box of poison; and although every precaution is taken to avoid the injurious influence of the emanations of the tree, yet of 700 criminals who went to collect the poison, scarcely two out of twenty returned. Foersch further adds, that for fifteen or eighteen miles around this tree no living animal of any kind has ever been discovered.2 Dr. Horsfield3 and M. Leschenault4 have shown that the above statements are for the most part fabulous. From their observations it appears that the *true poison tree* of Java is the *Antiaris toxicaria*5 (Fig. 290). It is one of the largest forest trees of Java, being from 60 to 100 feet high. The milky juice is collected by incision, and is then inpsissated by boiling along with the juice of arum, galanga, onions, &c. The poison, when brought to this country, is found to be a thick fluid of a grayish-brown or fawn-colour, and an unpleasant odour. It consists, according to Pelletier and Caventour, of a peculiar elastic resin, slightly soluble gummy matter analogous to bassorin, and a bitter matter, soluble in water. This bitter matter is composed of a colouring matter absorbable by charcoal, an undetermined acid, and antiarin, the active principle of the plant, and which is precipitable by tincture of galls. More recently, Mulder7 has submitted this juice to analysis, and found it to consist of *vegetable albumen* 16.14, gum 12.34, *anitarin* 20.92, *myricin* 7.02, *antiarin* 3.56, sugar 6.31, and *extractive* 33.70. The antiarin-resin was composed of *C14H20*. Antiarin consisted of *C14H20*. Sir B. Brodie8 says, the poison renders the heart insensible to the stimulus of the blood. Magendie and Delile9 found that, besides acting on the brain and spinal marrow, it proved emetic. According to Andrall, it causes convulsions, with alternations of relaxation.
Order XXXII. PIPERACEÆ, Richard.—PEPPERWORTS.

Characters.—Flowers naked, hermaphrodite, with a bract on the outside. Stamens 2 or more, arranged on one side, or all round the ovary; to which they adhere more or less; anthers 1—2-celled, with or without a fleshy connective; pollen roundish, smooth. Ovary superior, simple, 1-celled, containing a single erect, orthotropal ovule; stigma sessile, simple, rather oblique. Fruit superior, somewhat fleshy, indehiscent, 1-celled, 1-seeded. Seed erect, with the embryo lying in a fleshy sac, placed at the apex of the seed on the outside of the albumen.—Shrubs or herbaceous plants. Stems articulated. Leaves opposite, verticillate, or alternate, in consequence of the abortion of one of the pair of leaves. Stipules 0, or in pairs, or single and opposite the leaf. Flowers usually sessile, sometimes pedicellate, in spikes which are either terminal or axillary; or opposite the leaves (Lindley).

Properties.—Fruits remarkable for their hot taste, and acrid and stimulant properties. These qualities they owe to the presence of an acrid oil and resin.

121. PIPER NIGRUM, Linn.—THE BLACK PEPPER.

Sex. Syst. Diandria, Trigynia.

(Fructus immaturus, L.—Dried unripe berries, E. D.)

History.—The ancient Greeks were acquainted with pepper (πιπερος), their knowledge of which must have been derived, directly or indirectly, from the Hindoos. Hippocrates¹ employed it in several diseases. Pliny² notices its uses as a condiment,
and expresses his astonishment that it should have come into general use, since it
has neither flavour nor appearance to recommend it.

BOTANY. Gen. Char.—Spadix covered with flowers on all sides. Flowers
hermaphrodite, rarely dioecious, each supported by a scale. Stamina 2 or more.
Ovarium with 1 solitary erect ovule. Stigma panniform, obtuse, or split. Berry 1-seeded. Embryo dico-
tyledonous [monocotyledonous, Blume], inverted (Blume). ¹

Sp. Char.—Stem shrubby, radicant, climbing, terete. Leaves ovate or elliptical, acuminate, occasionally some-
what oblique, subcordate, 5—7-nerved, coriaceous, smooth, recurved at the margin, glauco-greenish beneath.
Spadixes shortly pedunculated, pendulous. Fruits distinct (Blume).²

Stem 8—12 feet long, jointed, dichotomous. Fruit at first green, then red, afterwards black.

According to Dr. Roxburgh,³ Piper trioeum is cultivated, and
yields excellent pepper.

Hab.—Cultivated in various parts of India and its
islands (Roxburgh), also in the West Indies.

Preparation.—When any of the berries on a spadix change from green to red,
the whole are considered fit for gathering; if, for, if they are allowed to become fully
ripe, they are somewhat less acid, and, moreover, easily drop off. When collected,
they are spread out and dried in the sun, and the stalks separated by hand-rubbing.
They are afterwards winnowed.⁴ The dried and shrivelled berries constitute black
pepper (piper nigrum).

White pepper (piper album) is prepared from the best and soundest grains, taken
at their most perfect stage of maturity. These being soaked in water, swell and
burst their tegument, which is afterwards carefully separated by drying in the sun,
hand-rubbing, and winnowing.⁵

Commerce.—The pepper countries extend from about the longitude of 90° to
that of 115° E., beyond which no pepper is to be found; and they reach from 5°
S. latitude to about 12° N., where it again ceases. The following estimate of the
production of pepper is drawn up by Mr. Crawford.⁶

Description.—Black pepper (piper nigrum) is round, covered externally with a
brownish-black corrugated layer (the remains of the succulent portion of the berry),
which may be readily removed by softening it in water. Internally we have a hard,
whitish, spherical, smooth seed, which is horny externally, but farinaceous internally.
The taste of both nucleus and covering is acid and hot. Amongst wholesale dealers
three sorts are distinguished:—

1. Malabar pepper.—This is the most valuable: it is brownish-black, free from
stalks, and nearly free from dust.

2. Penang pepper.—This is brownish-black, larger, smoother, free from stalks,
but very dusty. It is sometimes used in England to manufacture white pepper.

¹ Enum. Plant. Java, p. 64.
³ Marsden, op. cit.
⁴ Marsden, History of Sumatra, 3d edit. p. 137.
⁵ M'Culloch, Dict. of Commerce.
3. **Sumatra pepper.**—This is the cheapest sort. It is black, mixed with stalks, and contains much dust. (Under the name of Sumatra pepper, some dealers include the Penang or brownish-black sort, and the black Sumatra sort.)

The heavier the pepper is, the more it is esteemed in the market. The heaviest of all, being hard and smooth, is called shot pepper, which is either Malabar or Sumatra sort; the Penang sort never yielding this kind of pepper.

Most dealers sift their black pepper before offering it for sale, and use the dust (called P. D.) for pickling or grinding.

*Fulton's decorticated pepper* is black pepper deprived of its husk by mechanical trituration.

**Bleached pepper or English bleached pepper** is Penang pepper bleached by chlorine. In this state it ought perhaps to be classed among the white peppers.

**White pepper** (*piper album*) is the fruit deprived of the external fleshy portion of the pericarp. The grains are larger than those of black pepper, spherical, whitish, and smooth, horny externally; internally they are farinaceous or hollow in the centre. They are less acrid and pungent than black pepper. In commerce three sorts are distinguished:

1. **Tetlicherry pepper,** which is of two kinds. Large or fine Tetlicherry pepper is larger and whiter than any other description of white pepper, and fetches a higher price. Small or coriander-like pepper is shrivelled.

2. **Common white pepper** comes from Penang by Singapore. It is round and not shrivelled. Its value depends on its size and whiteness.

3. **English bleached white pepper.**—When the two preceding sorts are scarce, brown Penang pepper is bleached. The yellowest and largest grains are chosen for this purpose, for neither an expensive nor small sort would pay.

**Composition.**—In 1819, Oersted discovered *piperin* in pepper. In 1821, black pepper was analyzed by Pelletier. In 1822, white pepper was analyzed by Luci.²

Dr. Ure³ obtained from 100 parts of white peppercorns, a trace of volatile oil, 5½ grains of a pungent resin containing a small fraction of piperin, about 60 grains of starch with a little gum, and nearly 30 grains of matter (lignin) insoluble in hot or cold water.

Luci found no *piperin* in white pepper, but Poutet⁴ subsequently detected it. Probably, therefore, in Luci's analysis the piperin was contained in the resin.

1. **Resin of Pepper (resina piperis).**—This is a very acrid substance, soluble in alcohol and ether, but not so in volatile oils. It possesses in high perfection the acrid properties of pepper. Dissolved in ether, it was employed by Dr. Lucas in intermittents, and in two out of three cases with success.⁵ In the museum of the Pharmaceutical Society there are two kinds of pepper resin: one called the "green resin," the other the "red resin."

2. **Volatile Oil of Pepper (oleum piperis).**—When pure, this is colourless; it has the odour and taste of pepper. Its sp. gr. is 0.9332 (Luci). Its composition is C₁₀H₁₄O. It absorbs hydrochloric acid in large quantity, but does not form a crystalline compound with it. According to Mehl,⁶ it possesses the same febrifuge properties as piperin, perhaps because it retains some of the latter principle. It has been used in some forms of dyspepsia depending on general debility.

---

³ *Ann. de Chim. et de Phys.* xvi. 344.
⁴ Supplement to Ure's *Dict. of Arts*, p. 260, 1844.
⁵ *Journ. de Pharm.* t. vii.
3. Piperin.—This substance was discovered by Oersted in 1819, but was more accurately examined by Pelletier in 1821. It exists in black, white, and long pepper, and also in cubebs.

It is a crystalline substance, the crystals being rhombic prisms, with inclined bases. It fuses at 212° F., is insoluble in cold water, and is only very slightly soluble in boiling water. Its best solvent is alcohol: the solution throws down piperin when water is added to it. Ether dissolves it, but not so readily as alcohol. Acetic acid likewise is a solvent for it.

Piperin, when pure, is white; but, as met with in commerce, it is usually straw-yellow. It is tasteless and inodorous. It was at first supposed to be an alkali; but Pelletier has shown that it possesses no analogy with vegetable alkalies, and that it is related to the resins. With strong sulphuric acid it forms a blood-red liquid. Nitric acid colours it first greenish-yellow, then orange, and afterwards red. The action of hydrochloric acid is similar.

Its formula, according to Regnault, is C¹¹H¹⁹NO.²

Piperin has been recommended and employed by Meli and several other physicians¹ as a febrifuge in intermittent fevers. It is said to be more certain and speedy, and also milder in its action, than the cinchona alkalies. Moreover, we are told that it might be procured at a cheaper rate than sulphate of quina. Its dose is about six or eight grains in powder or pills. Sixty grains have been taken in twenty-four hours, without causing any injurious effects. Meli considers two or three scruples sufficient to cure an intermittent. Magendie² proposes it in hennorrhagia, instead of cubebs.

4. Starch.—Both black and white peppercorns contain abundance of very minute starch grains.

ADULTERATION.—Sago is said to have been used to adulterate ground white pepper. The microscope would readily detect the fraud; the starch grains of sago being very much larger than those of pepper, from which they also differ in shape. The following are the adulterations recently discovered³ in pepper by the microscope: wheat-flour, linseed meal, pea-flour, mustard-seed, and starch grains.

PHYSIOLOGICAL EFFECTS.—Pepper is one of the acid species whose general effects have been already noticed (see vol. i. p. 252). Its great acridity is recognized when we apply it to the tongue. On the skin it acts as a rubefacient and vesicant.⁴ Swallowed, it stimulates the stomach, creates a sensation of warmth in this viscus, and, when used in small doses, assists the digestive functions, but if given in large quantities induces an inflammatory condition. Thirty white peppercorns, taken for a stomach complaint, induced violent burning pain, thirst, and accelerated pulse, which continued for three days, until the fruits were evacuated.⁵ Wendt, Lange, and Jager⁶ have also reported cases in which inflammatory symptoms supervened after the use of pepper. On the vascular and secering systems pepper acts as a stimulant. It accelerates the frequency of the pulse, promotes diaphoresis, and acts as an excitant to the mucous surfaces. On one of my patients (a lady) the copious use of pepper induced burning heat of skin, and a few spots of Urticaria cuticulata usually on the face. "I have seen," says Van Swieten," "a most ardent and dangerous fever raised in a person who had swallowed a great quantity of beaten pepper." It has long been regarded as a stimulant for the urino-genital apparatus. The opinion is supported by the well-known influence of the peppers over certain morbid conditions of these organs. Moreover, the beneficial effect of pepper in some affections of the rectum leads us to suspect that this viscus is also influenced by these fruits.

USES.—It is employed as a condiment, partly for its flavour, partly for its stimulant influence over the stomach, by which it assists digestion. As a gastric stimulant it is a useful addition to difficulty-digestible foods, as fatty and mucilaginous matters, especially in persons subject to stomach complaints from a torpid or atomic condition of this viscus. Infused in ardent spirit it is a popular remedy for preventing the return of the paroxysms of intermittent fevers, given shortly before the expected attack. The practice is not recent, for Celsius⁷ advises warm water with pepper to relieve the cold fit. The febrifuge power of this spice has been fully proved, in numerous cases, by L. Frank,⁸ Meli,⁹ Riedmüller (Dierbach), and others;

¹⁰ Ibid. t. xiii. p. 104.
though Schmitz denies it. Barbier says that, in some instances, where large doses were exhibited, death occurred in consequence of the aggravation of a pre-existent gastritis. It has been employed in gonorrhoea as a substitute for cubebs. In relaxed uvula, paralysis of the tongue, and other affections of the mouth or throat requiring the use of a powerful acid, pepper may be employed as a masticatory. In the form of ointment it is used as an application to tinea capitis. Mixed with mustard, it is employed to increase the acidity of sinapisms.

**Administration.**—The dose of black pepper (either of corns or powder) is from five to fifteen grains; the powder may be given in the form of pills.

1. **Confectio Piperis, L.; Confectio Piperis Nigri, D.; Electuarium Piperis, E.; Confection of Black Pepper.**—(Black Pepper, Elecampane-root [Liquorice-root in powder, E.], of each 1 lb.; Fennel 1 lb.; Honey, White Sugar, of each 1 lb. Rub the dry ingredients together to a very fine powder, L. E.—Black Pepper in fine powder, Liquorice Root in powder, of each 5 zs; Refined Sugar ½ oz.; Oil of Fennel ½ oz.; Clarified Honey, by weight, 5½ oz. D. The London College keeps this in a covered vessel, and directs the Honey to be added when the Confection is to be used. But the Edinburgh and Dublin Colleges order the Honey to be added immediately after the ingredients have been mixed.)—This preparation is intended to be a substitute for a quack medicine, called "Ward's Paste," which has obtained some celebrity as a remedy for fistula, piles, and ulcers about the rectum. Its efficacy doubtless depends on the gentle stimulus it gives to the affected parts. Sir B. Brodie observes that severe cases of piles are sometimes cured by it; and he thinks that it acts on them topically, the greater part of the paste passing into the colon, becoming blended with the feces, and in this way coming into contact with the piles, on which it operates as a local application, much as \textit{vinum opii} acts on the vessels of the conjunctiva in chronic ophthalmia. In confirmation of this view, he mentions the case of a patient attended by Sir Everard Home, who was cured by the introduction of the paste into the rectum. Confection of black pepper is adapted for weak and lachrymephotic habits, and is objectionable where much irritation or inflammation is present. The dose of it is from one to two or three drachms twice or thrice a day. "It is of no use," says Sir B. Brodie, "to take this remedy for a week, a fortnight, or a month; it must be persevered in for two, three, or four months." As it is apt to accumulate in and distend the colon, gentle aperients should be exhibited occasionally during the time the patient is taking the confection.

2. **Unguentum Piperis Nigri; Ointment of Black Pepper.**—(Prepared Hog's Lard 1 lb.; Black Pepper, reduced to powder, ½ oz. Make an ointment.)—Formerly in vogue for the cure of tinea capitis.

[3. **Extractum Piperis Fluidum, U. S.; Fluid Extract of Black Pepper.**—Take of Black Pepper a pound; Ether a sufficient quantity. Put the powder into a percolator, and pour ether gradually upon it until two pints of filtered liquor are obtained. From this distill off, by means of a water-bath, at a gentle heat, a pint and a half of ether, and expose the residue, in a shallow vessel, until the whole of the ether has evaporated and the deposit of piperin and crystals has ceased. Lastly, separate the piperin by expression through a cloth and keep the liquid portion.

This preparation is of semifluid consistence, of a dark colour, and possessed strongly of the odour and taste of black pepper. It may be used where the article is usually employed. Dose, gtt. xx—½ oz.]
122. CHAVICA ROXBURGHII, Miguel.—COMMON LONG PEPPER.

Sex. Syst. Diandra, Trigynia.
(Fructus immaturus, L.—Dried Spikes, E.)

SYNONYMES.—Piper longum, Linn. in part; figure, in Nees' Plant. Medic. tab. 23.

History.—Long pepper (πιπερ μαξιόν) is mentioned both by Dioscorides and Galen. 3

BOTANY. Gen. Char.—Woody. Spikes solitary, opposite to the leaves. Flow ers sessile, dioecious. Bracts with short stalks, nearly quadrangular, peltate. Style very short or 0. Berries sessile, united with the permanent bracts and the thickened rachis of the spike. Seeds oblong or almost lenticular, with a crustaceous finely scrobiculate testa and a mealy albumen.

Sp. Char.—Rather hairy; lower leaves roundish ovate, 7-nerved; female spikes cylindrical, about as long as their stalk.

Hab.—India. Found wild among bushes on the banks of watercourses, up towards the Circur Mountains. It flowers and bears fruit during the wet and cold seasons (Roxburgh). It is cultivated in Bengal, and in the valleys amongst the Circur Mountains. The roots and thickest parts of the stems, when cut into small pieces and dried, form a considerable article of commerce all over India, under the name of Pippara muoda.

Description.—When fully grown, but yet unripe, the spadices are gathered and dried by exposure to the sun. They are then packed in bags for sale.

As met with in commerce, long pepper (piper longum) is grayish brown, cylindrical, an inch or more in length, having a mild aromatic odour but a violent pungent taste.

The long pepper imported from our possessions in India is the produce of Chavica Roxburghii, Mig. But that which is brought to Europe from the Dutch colonies is the produce of Chavica officinarum, Mig.

COMPOSITION.—This pepper was analyzed by Dulong in 1825. 5 The following are the substances he obtained from it: Acrid fatty matter (resin?), volatile oil, piperin, nitrogenous extractive, gum, balsamin, starch, malates and other salts.

The volatile oil of long pepper is colourless, and has a disagreeable odour and an acrid taste.

PHYSIOLOGICAL EFFECTS AND USES.—The effects of long pepper are analogous to those of black pepper. Cullen 6 and Bergius 7 consider it less powerful; but most other pharmacologists are agreed on its being more acrid. Medicinally it may be employed in similar cases. It is used principally for culinary purposes. It is a constituent of several pharmacopoeial preparations.

123. Chavica Betle, Miguel.—Betle Pepper.

Piper Betle, Linnaeus.—The leaf of this plant (as well as of Chavica Siriboa, Mig.) is extensively used by the Malays and other nations of the East, who consider it a necessary of life. The mode of taking it in Sumatra consists simply in spreading on the sirih (the leaf of the Chavica Betle) a small quantity of chamam (quicklime prepared from calcined shells). and folding it up with a slice of pining or Areca nut (see ante, p. 170). From the mastication there proceeds a juice which tinges the saliva of a bright red, and which the leaf and nut, without the lime, will not yield. This hue being communicated to the mouth and lips, is esteemed ornamental, and an agreeable flavour is imparted to the breath. The juice is usually, but not

always, swallowed. To persons who are not habituated to this composition it causes giddiness, astringes and excoriates the mouth and sauces, and deadens for a time the faculty of taste. Individuals, when toothless, have the ingredients previously reduced to a paste, that they may dissolve without further effort.1

124. CUBEBA OFFICINALIS, Miq.—THE CUBEB PEPPER.

Sex. Syst. Diandria, Trigyna.

(Fructus immaturus, L.—Fruit, E.—The berries, D.)

[Cubeba; Cubeb, U. S.]

SYNONYME.—Piper Cubeba, Linn. fil. Blume. Ph. L.

HISTORY.—It is somewhat doubtful when cubebes were first employed in medicine, and by whom they were first noticed. I am inclined to believe, however, that they are mentioned in the Hippocratic writings2 under the name of μυρτίδαςων; for 1stly, the remedy termed μυρτίδαςων is distinguished from pepper (πιπερο), and is said to be a round Indian fruit which the Persians call pepper. 2dly, the modern Greek name for cubebes is μυρτίδαςων.3

The word cubeb is derived from the Arabic name for these fruits, which first occurs in the writings of Serapion,4 Rhazes, and Avicenna. From the same source Actarius5 derived the name κυμβηδας, by which he has designated cubebes.

Cubebes were in use in England more than 500 years ago, for in 1305 Edward I. granted to the corporation of London the power of levying a toll of one farthing a pound on this article in its passage over London Bridge.6

Sp. Char.—Leaves smooth; the lower ones unequal, somewhat cordate at the base, ovate,acute; the upper ones more oblong-ovate, with rounded base and smaller; those of the male plant 5-nerved, of the female plant 5—9-nerved. Fruit globose, shorter than their stalks.—A climbing shrub.

Hab.—Grows wild in Bantam, the western part of Java; also on some of the neighbouring islands.—Cultivated in the lower parts of Java.

The above is, according to Miquel, the mother-plant of the genuine cubebes. But a neighbouring species—Cubeba canina, Miquel—yields a fruit which, according to Blume, also forms part of the cubebes of commerce. This plant grows on the Sunda and Molucca islands. The fruits and seeds of the two species are thus distinguished.

DESCRIPTION.—The dried unripe fruit of this plant constitutes the cubebes (cubeba vel piper caudatum) of the shops.

In appearance, cubebes resemble black pepper, except that they are lighter coloured,

1 Marsden, Hist. of Sumaira, 3d edit. p. 381.
2 De Morbis Multorum, lib. ii. p. 672, ed. Fussii.—The term μυρτίδαςως was also used to signify a myrtle-like plant, and likewise a rough excrescence growing on the μύρτινα (Ruscus aculeatus). See Dioscorides, lib. i. cap. 156.
3 Pharmacopoeia Graeca, Athens, 1827.
4 In his account of cubebes, Serapion has translated what Dioscorides has said of μύρτινα (Ruscus aculeatus) and added everything which Galen has stated respecting καρπάς. But Galen expressly states that καρπάς resembles τοῦ (the root of Valeriana Dioscorides) and it is improbable, therefore, that cubebes and cardamom should be identical.
5 C. Bambini Finess.—No Greek edition of Actarius has been published, and I am, therefore, obliged to quote his writings at second hand. In my copy of the Latin translation (De Medicina-montorum compositione, J. Ruello interprete, p. 60 b, 1560), the phrase runs thus—"arcescio (cubeb barbari vocant)."
and are each furnished with a stalk two or three inches long, and from which circumstance they have received their name caulatum ("fructus pedicellatus," Ph. Lond.). The cortical portion of cubenbs (that which constituted the fleshy portion of the fruit) appears to have been thinner and less succulent than in black pepper. Within it is a hard spherical seed, which is whitish and oily. The taste of cubenbs is acrid, peppery, and camphoraceous; the odour is peculiar and aromatic.

Composition.—Three analyses of cubenbs have been made: one by Tromms-dorff, in 1811; 1 a second by Vauquelin, in 1820; 2 and a third by Monheim, in 1835. 3

Vauquelin.
1. Volatile oil, nearly solid.
2. Resin, like that of copaiva.
3. Another coloured resin.
5. Extractive.

Monheim.
1. Green volatile oil.
2. Yellow volatile oil.
3. Cubebin.
4. Balsamic resin.
5. Wax.
6. Chloride of sodium.
7. Extractive.
8. Lignin.
Loss.

100.0

Cubenbs.

1. Essential Oil of Cubenbs.—(See p. 356.)
2. Resin of Cubenbs.—Vauquelin has described two resins of cubenbs: one is green, liquid, acrid, and analogous, both in odour and taste, to balsam of copaiva; the other is brown, solid, acrid, and insoluble in ether.

3. Cubebin (Piperin).—From cubenbs is obtained a principle to which the term cubebin has been applied. It is very analogous to, if not identical with, piperin. Cassola, a Neapolitan chemist, 4 says, it is distinguished from the latter principle by the fine crimson colour which it produces with sulphuric acid, and which remains unaltered for twenty or twenty-four hours; moreover, cubebin is not crystallizable.

Monheim, 4 however, declares cubebin to be identical with piperin, and that it is combined with a soft acrid resin. In this state it is soluble in ether, alcohol, the fixed oils, and acetic acid; but it is insoluble in oil of turpentine and dilute sulphuric acid. It fuses at 65° F.

Dr. Görres 5 gave cubebin, in both acute and chronic gonorrhoea, to the extent of one dram, four times daily. But he premised the use of phosphoric acid.

4. Extractive Matter of Cubenbs.—Vauquelin says, the extractive matter of cubenbs is analogous to that found in leguminous plants. It is precipitable by galls, but not by acetate of lead.

Physiological Effects.—Cubenbs belong to the acrid species already (see ante, p. 221) noticed. Their sensible operation is very analogous to that of black pepper. Taken in moderate doses, they stimulate the stomach, augment the appetite, and promote the digestive process. In larger quantities, or taken when the stomach is in an irritated or inflammatory condition, they cause nausea, vomiting, burning pain, griping, and even purging. These are their local effects. The constitutional ones are those resulting from the operation of an excitant—namely, increased frequency and fullness of pulse, thirst, and augmented heat. It probably stimulates all the mucous surfaces, but unequally so. In some instances cubenbs give rise to an eruption on the skin like urticaria. Not unfrequently they cause headache; and occasionally disorder of the cerebro-spinal functions, manifested by convulsive movements or partial paralysis, as in a case related by Mr. Broughton. 7

Cubenbs appear to exercise a specific influence over the urinogenital apparatus. Thus they frequently act as diuretics, and at the same time deepen the colour of, and communicate a peculiar aromatic odour to the urine. Their stimulant operation on the bladder is well illustrated by a case related by Sir Benjamin Brodie. 8

A gentleman, labouring under chronic inflammation of the bladder, took fifteen grains of cubenbs, every eight hours, with much relief. Being anxious to expedite his cure, he, of his own accord, increased the dose to a dram. This was followed by an aggravation of the symptoms: the irritation of the bladder was much in-

123456789

1. Schwartze, Pharm. Tabell.
2. Journ. de Pharm. xx. 403.
8. Ibid. vol. i. p. 500.
creased, the mucus was secreted in much larger quantity than before, and ultimately the patient died—"his death being, I will not say occasioned," adds Sir Benjamin, "but certainly very much hastened, by his imprudence in overdosing himself with cubebs."

Three drachms of cubebs caused in Pül1 nausea, acid eructations, heat at the pit of the stomach, headache, uneasiness, and fever.

Uses.—The principal use of cubebs is in the treatment of gonorrhœa. They should be given in as large a dose as the stomach can bear, in the early part of the disease; for experience has fully proved that, in proportion to the length of time gonorrhoea has existed, the less amenable is it to the influence of cubebs. In some instances an immediate stop is put to the progress of the malady. In others the violent symptoms only are palliated; while in many (according to my experience in most) cases no obvious influence over the disease is manifested. The presence of active inflammation of the urethra does not positively preclude the use of cubebs, though I have more than once seen them aggravate the symptoms. Mr. Jeffreys2 thinks the greatest success is met with in the more inflammatory forms of the disease. Cubebs have been charged with inducing swollen testicle; but I have not observed this affection to be more frequent after the use of cubebs than when they were not employed. Mr. Broughton3 gave them to fifty patients, and in forty-five they proved successful. Of these only two had swollen testicle. The explanation of the methodus medendi is unsatisfactory. Sir A. Cooper4 thinks that cubebs produce a specific inflammation of their own on the urethra, which has the effect of superseding the gonorrhœal inflammation. The occasional occurrence of a cutaneous eruption from the use of cubebs deserves especial attention, as I have known it create a suspicion of secondary symptoms.

Cubebs have been recommended in gleet and lencorrhea. In abscess of the prostate gland, twenty or thirty grains of cubebs, taken three times a day, have in many cases appeared to do good.6 They seemed to give a gentle stimulus to the parts, and to influence the disease much in the same way that Ward’s Paste operates on abscesses and fistulae, and ulcers of the rectum. In cystirrhœa also they have occasionally proved serviceable in small doses.7 In piles, likewise, they are given with advantage.8

The efficacys of cubebs in mucous discharges is not confined to the urinogenital mucous membrane. In catarrhal affections of the membrane lining the aerian passages, it proves exceedingly useful, especially when the secretion is copious and the system relaxed.

Formerly cubebs were employed as gastric stimulants and carminatives in dyspepsia, arising from an atomic condition of the stomach. They have also been used in rheumatism. The Indians macerate them in wine, and take them to excite the sexual feelings.

Administration.—Cubebs, in the form of powder, are given in doses varying from ten grains to three drachms. In affections of the bladder and prostate gland the dose is from ten grains to thirty grains. In gonorrhœa, on the other hand, they should be administered in large doses. Mr. Crawford9 says, that in Malay countries they are given in doses of three drachms, six or eight times during the day.

1. Oleum Cubebii, E.; Volatile Oil of Cubebs. (Prepared by grinding the fruit, and distilling with water.)—By distillation, cubebs yield about 10.5 per cent. of a transparent, slightly-coloured (when pure, colourless) volatile oil, which is lighter than water (sp. gr. 0.929), and has the cubeb odour, and a hot, aromatic, bitter taste. Its formula is C_10H_18.
By keeping, it sometimes deposits crystals (cubeb steaoptene or cubeb camphor), the primary form of which is the rhombic octohedron. They form a hydrate whose composition is C_{18}H_{26}O, the primary form of which is the rhombic octohedron. They form a hydrate whose composition is C_{18}H_{26}O. Their odour is that of cubeb; their taste, at first, that of cubeb and camphor, afterwards cooling. They are fusible at 133° F., soluble in alcohol, ether, and oils, but are insoluble in water. Oil of cubeb is an excellent and a most convenient substitute for the powdered. The dose of it, at the commencement of its use, is ten or twelve drops. This quantity is to be gradually increased as long as the stomach will bear it. In some instances, I have given it to the extent of a fluidrachm for a dose. It may be taken suspended in water by means of mucilage, or dropped on sugar; or in the form of gelatinous capsules of cubeb, a combination of oil of cubeb and oil of copaiva forms a very useful medicine in some cases of gonorrhoea.

2. **EXTRACTUM OLEO-RESINOSE CUBEBEE**; Oleo-resinous Extract of Cubeb.—Dublanc directs this to be prepared by adding the oil to the resinous extract of cubeb, which is prepared by digesting the cake, left after the distillation of the oil, in alcohol, and distilling off the spirit. The process of Mr. Procter, Jun., appears to be a better one. It consists in exhausting cubeb by ether in the displacement apparatus, and submitting the ethereal tincture to distillation in a water bath. The residual ethereal extract of cubeb is a dark olive brown colour, and contains all the volatile oil, cubebin, and resin (the active principles of the fruit) as well as most of the waxy matter, but none of the extractive. 1 lb. avoididupois of cubeb yields 2 oz. of ethereal extract. One drachm of it, therefore, is equal to one ounce of cubeb. It may be administered in the form of emulsion, pills, or capsules. Dose from grs. v to 3ss.

[3. **EXTRACTUM CUBEBEE FLUIDUM, U. S.**; Fluid Extract of Cubeb.—Take of Cubebes a pound; Ether a sufficient quantity. Put the cubebes into a percolator, and having packed it carefully, pour ether gradually upon it until two pints of filtered liquor are obtained, then distil off, by means of a water-bath at a gentle heat, a pint and a half of the ether, and expose the residue, in a shallow vessel, until the whole of the ether has evaporated. The above are the directions in full adopted by the U. S. Pharm. from Dr. Procter. The dose is as above stated.]

4. **TINCTURA CUBEBEE, L. [U. S.]; Tinctura Piperis Cubebae, D.; Tincture of Cubebes.—** (Cubebes, powdered, lbj [1/2v, D. (Siv, U. S.)]; Proof (Rectified, D.) Spirit Oij [Diluted Alcohol Oij, U. S.]. Macerate for seven [fourteen, D. (U. S.)] days, then express and strain.—Dr. Montgomery says, "I have found this tincture cure gonorrhoea, both speedily and satisfactorily." The dose of it is one or two drachms three times a day.

Some druggists keep a more concentrated tincture.

125. **Artanthe elongata, Miquel.—Matico-plant.**

*Sex. Syst. Dinandria, Monogynia.*

(Herba; folin.—The Leaves, D.)

Piper angustifolium, Ruiz and Pavon, Fl. Peruv.; Piper elongatum, Vahl.; Stephania elongata, Kunth; Moho Moho id est Nodus Nodus, vernacular name.—This plant has long been in use among the natives of Peru in venereal diseases; and having been employed on some occasion by a soldier as a mechanical agent to staunch blood, it got the name of the Soldier's herb, and, in 1839, was introduced into this country as an internal or chemical styptic. The term matico (matere o mation) is not exclusively applied to the leaves of this plant; but to those of others also. Dr. Lindley has given to the Museum of the Pharmaceutical Society some leaves of the Eupatorium glutinosum, Kunth. They are marked Matico, and are said to be excellent in powder for staunching blood and healing wounds. In appearance and texture they closely resemble the leaves of Artanthe elongata; and would, I doubt not, be equally valuable as mechanical styptics.

Artanthe elongata is a shrub of about 12 feet high, with jointed stem and branches. Its leaves are harsh, short-stalked, oblong lanceolate, acuminate; pulvinate beneath, tessellated or rough on the upper side on account of the sunken veins. The spikes are solitary, cylindrical,
and opposite the leaves; the bracts lanceolate; and the flowers hemaphrodite.—It grows at Huanuco, Cuchero, Pampa, Chacay, and Muna in Peru; and flowers from July to September.

Matico (herba matico vel matico) is imported in erons, and consists of the dried leaves, stalks, and spikes (some unripe, others ripe), and more or less compressed into a lump. The colour of the dried plant is greenish; and the leaves, which are from 2 to 8 inches long, in structure somewhat resemble those of sage, and are easily reducible to powder. The plant has an aromatic colour somewhat similar to that of cubebs.

Matico has been analyzed by Dr. J. F. Hodges, who found the following substances in it:— an aromatic volatile oil, a bitter principle (maticine), a soft dark green resin, a brown colouring matter, a yellow colouring matter, chlorophyll, gum and nitrate of potash, salts, and lignin.—The oil of matico has a light green colour, and when recent, the consistence of good castor oil, but becomes thick and crystalline on keeping. The bitter principle called maticine is soluble in alcohol and water, but not in ether.

Infusion of matico yields a dark greenish colouring and precipitate with the sesquichloride of iron, but undergoes no change on the addition of gelatin, emetic tartar, or perchloride of mercury. It, therefore, contains little or no tannin. Acetate of lead and infusion of nutgalls each occasion copious coloured precipitates.

Matico is an aromatic bitter stimulant, which agrees with cubebs and the pepper in the character of its effects. Its active principles are volatile oil, resin, and the bitter principle.

Matico may be used (like tinct, felt, cobweb, &c.) as a topical application for staunching blood, or from slight cuts and other wounds, leech-bites, the nose, gums, &c. It acts mechanically as a styptic by the structure of its leaf, which divides the blood and promotes its coagulation.

As an internal remedy it is applicable as a substitute for cubebs, in discharges from the mucous surfaces, as leucorrhæa, gonorrhæa, &c. It might, perhaps, be useful in affections of the rectum, in similar cases to those in which the confection of pepper has been serviceable. The Indians use the infusion as an aphrodisiac.

Matico has been greatly looked on as an internal styptic or astringent in internal hemorrhages (from the lungs, stomach, bowels, and uterus). But the botanists, chemists, and sensible qualities of matico are opposed to the idea of its astringent properties; and with regard to the supposed therapeutic evidence, it may be observed that from the often temporary character and uncertain duration of internal hemorrhages generally, it is very difficult to determine the therapeutic influence of the agents called astringents, and to distinguish post hoc from propter hoc phenomena. If matico have any styptic power, it is derived not from tannic or gallic acids, but from the volatile oil which the plant contains; and in that case the oils of pepper, cubebs, or turpentine, would be much more energetic and preferable.

[Dr. Ruschenberger, who became acquainted with it during a visit to Peru in 1834, and introduced it into the United States, has used it locally in chronic ophthalmia with advantage. With regard to its anti-hemorrhagic power, the latter gentleman informs me that he applied it to arrest hemorrhage after an operation on the side of the neck below the angle of the jaw, in which there was considerable bleeding and difficulty in taking up the divided vessels, owing to induration of the part from chronic inflammation; and the application was successful. The same arrest of the discharge of blood followed its use in hæmatemesis.]

Matico is administered in the form of powder, infusion, and tincture. The dose of the powder is from 7½ to 15 grs.

1. Infusion Matico, D.; Infusion of Matico.—(Matico Leaves, cut small, 32 grs; Boiling Water Oss. Infuse for one hour, in a covered vessel, and strain. The product should measure about eight ounces, D.)—Dose from 1/2 to 3/4 gr.

2. Tinctura Matico, D.; Tincture of Matico.—(Matico Leaves, in coarse powder, 3/8 gill; Proof Spirit Oij. Macerate for fourteen days, strain, express, and filter, D.)—Dose from 1/3 to 1/2 gill.

ORDER XXXIII. EUPHORBIACEÆ, Juss.—SPURGEWORTS.

EUPHORBIA, Juss.

Characters.—Flowers unisexual. Calyx free (inferior), with various glandular or seamy internal appendages; sometimes wanting. Corolla usually absent, sometimes polypetalous or monopetalous. Stamina definite or indefinite, distinct or monodelphous; anthers 2-celled. Ovary free (superior). Ovules solitary or twin, suspended from the inner angle of the cell. Fruit generally tri-carpocorous, consisting of 3 carpels splitting and separating with elasticity from their common axis, occasionally fleshy and indehiscent. Seeds solitary or twin, suspended often with an aril; embryo enclosed in fleshy albumen; cotyledons flat; radicle superior. Trees, shrubs, or herbs, often abounding in a milky juice. Leaves opposite or alternate, simple, rarely compound, often with stipules. Flowers axillary or terminal, sometimes inclosed within an involucre re

2 Peppermint and other labiate plants yield infusions which produce a dark green colour with the sesquichloride of iron.
semelling a calyx. Some of the Euphorbiaceae are succulent or fleshy, and have a considerable resemblance to Cactaceae; from which they may in general be distinguished by the presence of an acrid milky juice.

Properties.—Mostly acrids; operating, toxicologically, as acrid, narcotic-acrid, or acro narcotic poisons; and medicinally, as rubefacients, suppurants, emetics, diuretics, and cathartics. The acrid or poisonous principle or principles reside in the roots, stems, leaves and seeds. It is a constituent of the acrid milky juice found in many of the species. "M. Berthollet has recorded a remarkable instance of the harmless quality of the sap in the interior of a plant, whose bark is filled with a milky proper juice of a poisonous nature. He described the natives of Tenerife as being in the habit of removing the bark from the Euphorbia canariensis, and then sucking the inner portion of the stem in order to quench their thirst, this part containing a considerable quantity of limpid and non-elaborated sap. 31 In some cases an acrid principle (see vol. i. p. 206) is found in the embryo, but not in the albumen of the seed. Thus Aublet 3 states that the kernels of Omphalea diandra are edible if the embryo be extracted; but if this be left in, they prove cathartic. In some cases, however, as those of Croton and Ricinus, the albumen also possesses acrid and poisonous properties. The chemical nature of the acrid principle or principles has not been determined. In some cases it appears to be volatile, in others fixed. If it be true that persons have been poisoned by sleeping under the Mancineel tree (Hippomane Mancinella), this species must give out a poisonous vapour. In some cases, however, resin appears to be the active principle; as in the officinal substance called gum euphorbium.

The expressed oils of the seeds of several of the Euphorbiaceae (as Croton, Ricinus, Jatropha, Euphorbia, and Andra) are purgative; in some cases violently so. They probably owe this to some active principle dissolved in the fixed oil; for the residual oil cake acts as a drastic purgative, in some cases more so than the expressed oil. Soubeiran 3 thinks that some of the euphorbiaceous seeds owe their purgative qualities to resin. The fixed oil of some of the seeds is remarkable for its more ready miscibility with, or solubility in, alcohol, than most other fixed oils.

Some euphorbiaceous plants are devoid of acridity, or possess it in a very slight degree only. Some of these are aromatic, resiniferous, and tonic. Von Buch 4 says, the branches of Euphorbia balamifera contain a mild sweet juice, which is eaten by the inhabitants of the Canary Isles. The aromatic tonic bark of the Croton Eleutheria is another exception to the very general acridity of these plants.

Some of the roots are harmless and nutritious. Others of neighbouring species abound in nutritive starch (e.g., tapioca-starch), which resides in a poisonous juice.

126. EUPHORBIA CANARIENSIS, Linn.—THE CANARY EUPHORBIUM.

Sect. Syst. Dodecanandra, Trigynia, Linn.—Monoezia, Monandria, Smith.

(Euphorbium; gummi-resina, L. D.—Concrete resinous juice, E.)

History.—The plant which yields the salme waxy-resin called in the shops gum euphorbium, is said both by Dioscorides 5 (who calls it ἐφορβία) and Pliny 6 to have been first discovered in the time of Juba, king of Mauritania; that is, about, or a few years before, the commencement of the Christian era. Pliny says that Juba called it after his physician, Euphorbus; and that he wrote a volume concerning it, which was extant in Pliny's time. Salmisius, however, states that this word occurs in the writings of Meleager the poet, who lived some time before Juba. But in the passage in question the commonly received reading in the present day is not ἐφορβία, but ἐφορβίον. 7

Botany. Gen. Char.—Flowers collected in monocious heads, surrounded by an involucre consisting of 1 leaf with 5 divisions, which have externally 5 glands alternating with them. Males naked, monandrous, articulated with their pedicel, surrounding the female, which is in the centre. Females naked, solitary. Ovarium stalked. Stygmas 3, forked. Fruit hanging out of the involucre, consisting of

---

3 Journ. de Pharm. t. xv. p. 501, 1839.
3 cells, bursting at the back with elasticity, and each containing 1 suspended seed (Lindley).

Sp. Char.—Branches channelled, with 4, rarely 5, angles, armed with double, straight, spreading, dark, shining spines.

These specific characters apply to the branches found mixed with the euphorbium of commerce. They agree with the description and figure of Tithymalus aizoides lactifluus seu Euphorbia canariensis of Plukenet. This agrees with the statement of Miller, who states that by looking over some euphorbium in a shop, he "found several spines amongst it, which exactly agreed with those of that plant." I feel very little hesitation, therefore, in referring the euphorbium of English commerce to E. canariensis; the species still retained by the Dublin College.

From the E. canariensis of Wildenow and of some other botanists, this plant is distinguished by its straight spines; but on examining the E. canariensis at the Kew Garden, I find as many of the spines straight as uncinate. The diameter of the stems, however, and even of the young shoots, is greater than that of stems found in the euphorbium of commerce. The species which most closely agrees with the latter in the sizes of the stems, the number of angles, and the number and directions of the spines, is Euphorbia tetrodona. This species has mostly square stems; though some of the larger stems are somewhat channelled. The dried stems found in the euphorbium of commerce, however, appear to be uniformly channelled. The E. officinarum (adopted by the London College) has many angles; the Derrymale of Jackson has many scollopated angles. Euphorbia antiquorum has been said to yield euphorbium, but the statement is denied by both Hamilton and Royle.

Hab.—The Canary Islands; Africa, in the neighbourhood of Mogadore?

Extraction.—Euphorbium is thus procured: The inhabitants of the lower regions of the Atlas range make incisions in the branches of the plant, and from these a milky juice exudes, which is so acrid that it excoriates the fingers when applied to them. This exuded juice hardens by the heat of the sun, and forms a whitish-yellow solid, which drops off in the month of September, and forms the euphorbium of commerce. "The plants," says Mr. Jackson, "produce abundantly once only in four years; but this fourth year's produce is more than all Europe can consume." The people who collect it, he adds, are obliged "to tie a cloth over their mouth and nostrils to prevent the small dusty particles from annoying them, as they produce incessant sneezing." The acrid resinous juice resides in the outer or cortical portion of the stem (see ante, p. 359).

Properties.—Euphorbium consists of irregular yellowish, slightly friable tears, usually pierced with one or two holes, united at the base, and in which we find the remains of a double aculeus. These tears are almost odourless; but their dust, applied to the olfactory membrane, acts as a powerful sternutatory. Their taste is at first slight, afterwards acid and burning. When heated, euphorbium melts, swells up imperfectly, evolves an odour somewhat like that of benzoic acid vapour, takes fire, and burns with a pale flame. Alcohol, ether, and oil of turpentine are its best solvents; water dissolves only a small portion of it.

Composition.—Euphorbium has been the subject of several analyses—namely, in 1800, by Laudet; in 1809, by Braconnot; in 1818, by Pelletier and by Mühlmann; in 1819, by Brandes; and more recently by Drs. Buchner and Herberg.
Resin is the active ingredient of euphorbium. It coincides in many of its properties with ordinary resins; thus, it is reddish-brown, hard, brittle, fusible, soluble in alcohol, ether, and oil of turpentine, and somewhat less so in oil of almonds. Its leading and characteristic property is intense acidity. It differs from some resins in being slightly soluble only in alkalies. It is a compound of two resinous substances.

a. One resinous substance is soluble in cold alcohol. Its formula, according to Mr. Johnston,\(^1\) is \(\text{C}^8\text{H}_{10}\text{O}_4\).

b. The other resinous substance is insoluble in cold alcohol. The mean of Rose’s analyses\(^2\) gives as the composition of this resin, carbon 81.58, hydrogen 11.35, and oxygen 7.07.

Physiological Effects. a. On Animals generally.—Euphorbium acts on horses and dogs as a powerful acrid substance, irritating and inflaming parts with which it is placed in contact, and affecting the nervous system. When swallowed in large quantities, it causes gastro-enteritis (two ounces are sufficient to kill a horse); when applied to the skin, it acts as a rubefacient and epispastic. Farriers sometimes employ it, as a substitute for cantharides, for blistering horses, but cautious and well-informed veterinarians are opposed to its use.

b. On Man.—The leading effect of euphorbium on man is that of a most violent acid, but under certain circumstances a narcotic operation has been observed. When euphorbium dust is inhaled, and also applied to the face, as in grinding this drug, it causes sneezing, redness, and swelling of the face, and great irritation about the eyes and nose. To prevent as much as possible these effects, various contrivances are adopted by different drug-grinders; some employ masks with glass eyes, others apply wet sponge to the nose and face, while some cover the face with crape. The pain and irritation, I am informed, are sometimes very great. Individuals who have been exposed for some time to the influence of this dust, suffer with headache, giddiness, and ultimately become delirious. All the workmen of whom I have inquired (and they comprise those of three large firms, including the one alluded to by Dr. Christison) agree that these are the effects of euphorbium. An old labourer assured me that this substance produced in him a feeling of intoxication; and I was informed at one drug-mill of an Irish labourer who was made temporarily insane by it, and who, during the fit, insisted on saying his prayers at the tail of the mill-horse.

Insensibility and convulsions have been produced by euphorbium. The only instance I am acquainted with is the following: A man was engaged at a mill where euphorbium was being ground, and remained in the room longer than was considered prudent. Suddenly he darted from the mill-room, and ran with great velocity down two pairs of stairs. On arriving at the ground-floor or yard he became insensible, and fell. Within five minutes I saw him: he was lying on his back, insensible and convulsed; his face was red and swollen, his pulse frequent and full, and his skin very hot. I bled him, and within half an hour he became quite sensible, but complained of great headache. He had no recollection of his flight down stairs, which seems to have been performed in a fit of delirium.

When powdered euphorbium is applied to the skin, it causes itching, pain, and inflammation, succeeded by vesication.

When swallowed, it causes vomiting and purging, and, in large doses, gastro-enteritis, with irregular hurried pulse and cold perspirations.

Uses.—Notwithstanding that it is still retained in the Pharmacopoeia, it is rarely employed in medicine. It was formerly used as an emetic and drastic purgative in dropseys, but the violence and danger of its operation have led to its disuse. Sometimes it is employed as an erthine in chronic affections of the eyes, ears, or brain; but its local action is so violent that we can only apply it when largely diluted with some mild powder, as starch or flour.

Mixed with turpentine or Burgundy pitch (or resin), it is employed in the form of plaster, as a rubefacient, in chronic affections of the joints. As a vesicant, it is rarely employed. As a caustic, either the powder or alcoholic tincture (Tinctura Euphorbi, Cod. Hamburg, prepared by digesting euphorbium \(5j\), in rectified spirit \(1j\)) is sometimes employed in various ulcers.

\(^1\) Phil. Trans. 1840, p. 365.
\(^2\) Poggendorff’s Annalen, xxxiii. 92.
VEGETABLES.—NAT. ORD. EUPHORBIACEÆ.

ANTIDOTE.—In a case of poisoning by euphorbium, emollient and demulcent drinks, elysters (of mucilaginous, amylaceous, or oleaginous liquids), and opium, should be exhibited, and blood-letting and warm baths employed. In fact, as we have no chemical antidote, our object is to involve the poison in demulcents, to diminish the sensibility of the living part by opium, and to obviate the inflammation by blood-letting and the warm bath. If the circulation fail, ammonia and brandy will be required.

127. Euphorbia Lathyris, Linn.—Caper Spurge.

(Semina.)

This is an indigenous or naturalized biennial plant, which is cultivated in gardens. Stem solitary, erect, 2 or 3 feet high, purplish, round, smooth, like every other part. Leaves numerous, spreading in 4 rows, opposite, sessile, oblong, acute, entire, of a dark glaucous green; their base heart-shaped; the lower ones gradually diminishing. Umbel solitary, terminal large, or 4 repeatedly forked branches. Bracts heart-shaped, entire, tapering to a point. Flowers sessile in each fork, solitary, variegated with yellow and dark purple. Nectaries rounded with blunt horns. Capsules large, smooth (Smith).—The seeds (sem. euphorbia lathyris; sem. cataputia minoris; grana regia minora) are about the size of peppercorns. They yielded Soubeiran1 a yellow fixed oil, stearine, a brown acid oil, a crystalline matter, a brown resin, an extractive colouring matter, and vegetable albumen. The yellow fixed oil is purgative, but it owes this property to matters which it holds in solution. The brown acid oil is the active principle: it has a disagreeable odour, approaching that of croton oil, and readily dissolves in alcohol and ether. Oil of caper spurge (oleum euphorbia lathyris) may be obtained by expression, by alcohol, or by ether. The expressed oil, unlike that of croton oil, is insoluble in alcohol. It is less active than the oil prepared by alcohol (as 3 is to 2). Both the milky juice of the plant and the seeds are acrid, and violently purgative. In a case of poisoning by the seeds, narcotic symptoms also were present.2 The oil may be employed as an indigenous substitute for croton oil. The dose of it is from three to ten drops.3 The capsules are pickled and used as a substitute for capers, which they resemble in size, appearance, and pungency. When recent, they are certainly acrid and poisonous; and it is probable, therefore, that the pickling process lessens or destroys their virulence; but the free use of the pickled fruits is dangerous.

128. Euphorbia Ipecacuanha, Linn.—Ipecacuanha Spurge.

(Radix.)

This plant (also called American Ipecacuanha) is a native of the United States of America. The dried root (radix euphorbiae ipecacuanha; vel rad. ipecacuanha spuriae alba) is cylindrical, grayish yellow, inodorous, and has a sweetish, not unpleasant taste. According to Dr. Bigelow, it contains caoutchouc, resin, gum, and probably starch. Its active principle is perhaps resin. This root is an energetic, tolerably certain emetic, rather milder than E. corollata, but, like that, disposed to act upon the bowels, and liable, if given in over doses, to produce excessive nausea and vomiting, general prostration, and alarming hyperaetharisis. It is, therefore, wholly unfit to supersede ipecacuanha.4 The dose of the powdered root is from ten to fifteen grains. In small doses it is diaphoretic.

TRIBE. CROTONÆ, Blume.

Ovule solitary. Flowers usually having petals, in clusters, spikes, racemes, or panicles.

129. CROTON TIGLIUM, LAM.—THE PURGING CROTON.

Croton Jamalgota, Hamilton.

Sex. Syst. Monocæ, Monadelphæ.

(Oleum et semine expressum, L.—Expressed Oil of the Seeds, E. D. [U. S.])

HISTORY.—Croton seeds are mentioned by Avicenna5 and by Scrapion6 under the name of Dend or Dende. The earliest European describer of them is Christopher

6 De Simplicibus, ccxlviii.
d'Acosta, in 1578,¹ who terms them *pini nuclei malucani.* When Commeline wrote, they were known in the shops by the name of *catoputia minor,* although they were sold by itinerants as *grana illia* or *grana illii.* They were much employed by medical men in the 17th century, and were known by various names, but principally by that of *grana tiglia.* They, however, went out of use, probably in consequence of the violence and uncertainty of their operation. Their re-employment in modern practice is owing partly to the notices of them by Dr. White and Mr. Marshall, in the first edition of Dr. Ainslie's work;² but principally to the introduction of the oil, in 1820, by Dr. Conwell.³

**Botany. Gen. Char.**—*Flowers* monocious, or very rarely dioecious. *Calyx* 5-parted. **Males:** petals 5; stamens 10 or more, distinct. **Females:** petals 0; styles 3, divided into two or more partitions. *Capsule* trilocous [with one seed in each cell] (Adr. de Jussieu).

**Sp. Char.**—Arborescent. *Leaves* oblong-ovate, acuminate, 3—5-nerved, slightly serrate, smooth. *Stamina* 15, distinct. Each cell of the fruit filled by the seed. A middle-sized tree, from 15 to 20 feet high. *Bark* smooth, ash-coloured. *Leaves* thin and membranous, sometimes cordate, and with two flat round glands at their base; when young, covered on both surfaces, but especially the lower one with minute stellate hairs. At the base of the leaves are two flat round glands. *Raceme* terminal, erect, simple. *Petals* of male flower white.

**Hab.**—Continent of India, islands forming the Indian Archipelago, and Ceylon.

The *Croton Pavana*⁴ is said also to yield tiglium or croton seeds. It is distinguished from *C. Tigilum* by having only ten stamina, and by the seeds being much smaller than the cells in which they are placed. *C. Pavana* is a native of Ava, north-eastern parts of Bengal! An English! Dr. Hamilton thinks it is the *Granum Malucum* of Rumphius.

**Description.**—Croton seeds (*semina tiglii seu semina crotonis, grana tiglii, purging nuts of some authors*) in size and shape are very similar to castor seeds. Viewed laterally, their shape is oval or oval-oblong; seen from either extremity, they have a rounded or imperfectly quadrangular form. Their length does not exceed 6 lines, their thickness is 2½ to 3 lines, their breadth 3 or 4 lines. Sometimes the surface of the seeds is yellowish, owing to the presence of an investing lamina (epidermis?). The testa is dark brown or blackish, and is marked with the ramifications of the raphé. The endocarp, or internal seed-coat, is thin, brittle, and of a light colour. It encloses a yellowish oily albumen, which envelops the embryo, whose cotyledons are foliaceous or membranous. The seeds are without odour; their taste is at first mild and oelaginous, afterwards acrid and burning. When heated, they evolve an acrid vapour. The proportion of shell and kernel in 100 parts by weight of the seeds is thus stated by two authorities:

**Composition.**—Croton seeds were analyzed in 1818 by MM. Pelletier and Coventon,⁵ in 1822 by Dr. Nimmo,⁶ and in 1823 by Brande.⁷ The following are their results:

¹ Chusius, Exotica, p. 222.
⁴ Journ. de Pharm. t. iv. p. 289, 1818; and t. x. p. 10, 1825. In the first paper, croton seeds were, by mistake, said to be the seeds of *Jatropha Cucana.* Coventon corrected this statement in the second paper. In the Journ. de Pharm. et de Chim. for March 1820, M. Guibord states that he has recently ascertained that the seeds of *J. Cucana* are sold by respectable dealers in Paris for croton seeds. It is stated by Mr. Frost (Lond. Medici. Reposit. vol. xvii. p. 461, 1822; and vol. xviii. p. 474, 1823) that in England, the former seeds have been mistaken for the latter.
⁵ Quarterly Journal of Science, vol. xiii. p. 92, 1822. Souleiman (Journ. de Pharm. t. iv. p. 514, 1820) states, though I know not on what authority, that the oil which Dr. Nimmo analyzed under the name of croton oil, was extracted from the Jatropha.
1. **Volatile Oil of Croton Seeds.**—This is but imperfectly known, traces only of it having been obtained. Brandes regards it as extremely acid, and thinks that by the united agencies of air and water it is converted into crotonic acid; for the distilled water of the seeds becomes more acid by keeping.

2. **Fixed Oil of Croton Seeds.**—This also is but imperfectly known. It must not be confounded with croton oil of the shops, which is a mixture of this and other constituents of the seeds. Fixed oil of croton seeds is, probably, a combination of crotonic and other fatty acids with glycine.

3. **Crotonic Acid.** *(Jatrophy Acid.)*—Discovered by Pelletier and Caventou. Though this acid exists in the free state in the seed, yet an additional quantity of it is obtained when the oil is saponified. For this purpose the oil is saponified by potash; the resulting soap decomposed by tartaric acid, and the watery fluid, from the surface of which the separated common fatty acids have been removed, is to be submitted to distillation. In this way is obtained an aqueous solution of a solid, very volatile, fatty acid, which congeals at 23° F., and, when heated a few degrees above 32° F., is converted into vapour, having a strong nauseous odour, and which irritates the eyes and nose, and has an acid taste.

At first Pelletier and Caventou regarded this acid as the active principle of the oil; but Caventou subsequently expressed doubts on the subject, and stated that fresh experiments induced him to think that the irritating and volatile principle of the oil, and which so strongly irritated the nose and eyes, is not of an acid nature. My colleague, Mr. Redwood, informs me that he has ascertained that crotonic acid and the crotonates are inert, or nearly so; and in experiments with crotonic acid prepared by him support his statements.

Crotonic acid unites with bases forming a class of salts called crotonates, which are inorganic. The crotonate of ammonia precipitates the salts of lead, copper, and silver, white; and the sulphate of iron, yellow. Crotonate of potash is crystalline, and dissolves, with difficulty, in alcohol. Crotonate of barytes is soluble in water; but crotonate of magnesia is very slightly soluble only in this liquid.

4. **Crotonin.**—The crystallizable substance which Brandes thought to be a peculiar alkaloid, and which he called crotonin, and which appeared to be identical with the tigin of Adr. de Jussieu, has been found by Weppen 1 to be (as formerly suggested by Soubeiran 2) a magnesium sap with an alkaline reaction.

5. Resin.—Is brown and soft; and has a disagreeable odour, on account, doubtless, of the oil which it retains. It is soluble in alcohol, but insoluble in ether and in water. The alkalies dissolve it by separating a whitish matter. It contributes to the purgative properties of croton oil.

**Physiological Effects.** 1. **Of the Seeds.**

a. **On Animals generally.**—Croton seeds are powerful local irritants or acrids, causing inflammation in those living parts with which they are placed in contact. Orfila 3 found that three drachms being introduced into the stomach of a dog, and the oesophagus tied to prevent vomiting, caused death in three hours; and on examination of the body, the alimentary canal was found to be in a state of inflammation. In another experiment, a drachm caused death under the same circumstances. A drachm, also, applied to the cellular tissue of the thigh, was equally fatal. A dose of from twenty to thirty grains of the powder of the kernel given to the horse causes, in six or eight hours, profuse watery stools, and is recommended by some veterinarians as a purgative; but the uncertainty of its operation, and the gripping and debility which it occasions, are objections to its use. 4 Lansberg 5 found that twenty of the seeds killed a horse, by causing gastro-enteritis. The pulse was frequent, small, and soft.

b. **On Man.**—In the human subject a grain of croton seed will frequently pro-

---

duce full purgation. Mr. Marshall\(^1\) says that this quantity, made into two pills, is about equal in power to half a draechm of jalap, or to six grains of calomel. The operation, he adds, is attended with much rumbling of the bowels; the stools are invariably watery and copious. Dr. White recommends the seeds to be torrefied, and deprived of their seed-coats, before employing them.\(^2\) Dr. Wallich informed me that the labourers in the Calcutta Botanic Garden were in the habit of taking one of these seeds as a purgative, but that on one occasion this dose proved fatal.

The seed-coats, the embryo, and the albumen, have each in their turn been declared to be the seat of the acrid principle; I believe the remarks which I shall have to make with respect to the seat of the acridity of castor-oil seeds, will apply equally well to that of croton seeds.

The following is a case of poisoning by the inhalation of the dust of the seeds:

Thomas Young, aged 31, a labourer in the East India warehouses, was brought into the London Hospital on the 8th of December, 1841, labouring under symptoms of poisoning by the inhalation of the dust of croton seeds. He had been occupied about eight hours in emptying packages of these seeds, by which he was exposed to their dust. The first ill effects observed were loss of appetite, then a burning sensation in the nose and mouth, tightness at his chest, and copious lachrymation, followed by epigastric pain. Feeling himself getting worse, he left the warehouse, but became very giddy, and felt down insensible. Medical assistance was procured, an emetic was administered, stimulants were exhibited, and he was wrapped in warm blankets. When he became sensible, he complained of his mouth being parched, and that his throat was swelling. He was then removed to the hospital. On his admission he appeared in a state of collapse, complained of burning pain at the stomach, in the throat, and in the head, and of swelling and numbness of his tongue. The epigastrium felt hot and tense, the pupils were dilated, the breathing short and hurried, the countenance distressed, pulse 85, surface cold. He stated that his tongue felt too large for his mouth, and appeared to be without feeling, and he had bitten it two or three times to ascertain whether there was any sensation in it. On examination, however, no change could be observed in the size or appearance of the tongue or parts about the mouth. Hot branly and water were given to him, and he was put into the hot bath with evident relief. He continued in the hospital for several days, during which time he continued to improve, but still complained of epigastric pain. It deserves notice that his bowels were not acted on, and on the day following his admission several doses of castor-oil were given to him.

It would be interesting to know whether the seeds of Croton Pavana are equally active with those of Croton Tigillum; and, also, whether the seeds of both species are found in commerce.

2. Of the Oil. a. On Animals generally.—On vertebrated animals (horses, dogs, rabbits, and birds), it acts as a powerful local irritant or acrid. When taken internally, in moderate doses, it operates as a drastic purgative; in large doses, as an acrid poison, causing gastro-enteritis. Moiroud\(^3\) says, that from twenty to thirty drops of the oil are, for the horse, equal to two drops for a man; and that twelve drops injected into the veins cause alvine evacuations in a few minutes. Thirty drops administered in the same manner, have caused, according to this veterinarian, violent intestinal inflammation and speedy death. A much less quantity (three or four drops) has, according to Hertwich,\(^4\) terminated fatally when thrown into the veins. After death the large intestines have been found to be more inflamed than the small ones. Flies, which had eaten some sugar moistened with the oil of croton, died in three or four hours—the wings being paralyzed or incommensurable before death.

3. On Man.—Rubbed on the skin it causes rubefaction and a pustular or vesicular eruption, with sometimes an erysipelatous swelling of the surrounding parts. When rubbed into the abdomen, it sometimes, but not invariably, purges. Rayer\(^5\) mentions a case in which thirty-two drops rubbed upon the abdomen produced purging, large vesicles, swelling, and redness of the face, with small, prominent, white, crowded vesicles on the cheeks, lips, chin, and nose. Applied to the eye, it gives rise to violent burning pain, and inflammation of the eye and face. In one

---

\(^3\) *Pharm. Véter.* p. 372.
\(^5\) *Treatise on Diseases of the Skin*, by Dr. Willis, p. 307.
case it produced giddiness. Ebeling obtained relief by the application of a solution of carbonate of potash. Swallowed in small doses, as of one or two drops, it usually causes an acid burning taste in the mouth and throat, and acts as a drastic purgative, giving rise to watery stools, and frequently increasing urinary secretion. Its operation is very speedy. Frequently it causes evacuations in half an hour: yet it is somewhat uncertain. Sometimes six, eight, or even ten drops may be given at a dose without affecting the bowels. In moderate doses it is less disposed to cause vomiting or purging than some other cathartics of equal power. Mr. Iliff, however, observes that it produces nausea and gripping more frequently than has been supposed.

The following is a case of poisoning by an excessive dose of croton oil: A young man, aged 25, affected with severe typhoid fever, swallowed by mistake two and a half drachms of croton oil. At the end of three-quarters of an hour the skin was cold and covered with cold sweats, the pulse and action of the heart scarcely perceptible, respiration difficult; the points of the toes and fingers, the parts around the eyes and the lips, blue, as in malignant cholera; abdomen sensible to the touch; but no vomiting. In an hour and a half there were excessive and involuntary alvine evacuations, sensation of burning in the oesophagus, acute sensibility of the abdomen, skin colder, respiration and circulation difficult, the cyanosis extended over the whole body, the skin became insensible; and death occurred, with some of the symptoms of asphyxia, four hours after the poison was swallowed. No lesion was found in the gastric membrane. The intestines presented ulcerations such as are characteristic of typhus fever.

In comparing croton oil with other violently acid purgatives, we find it distinguished by its speedy operation, the great depression of the vascular system as well as the general feeling of debility which it produces, and by the uncertainty of its operation.

Uses.—The value of croton oil as an internal remedial agent depends principally on two circumstances—first, its powerful and speedy action as a drastic cathartic, by which it is adapted for obviating constipation, or for operating on the bowels as a counter-irritant; and secondly, on the smallness of the dose, which in practice presents many advantages. These circumstances render it peculiarly applicable in cases requiring powerful and speedy catharsis, and in which the patient cannot swallow, or does so with extreme difficulty, as in trismus, coma, and some affections of the throat; or where he will not swallow, as in mania. In all such cases the oil may be dropped on the tongue. In obstinate constipation, whether from the poison of lead or from other causes, it has sometimes succeeded where other powerful cathartics had been tried in vain. It is especially serviceable where the stomach is irritable, and rejects more voluminous purgatives; and it is of course objectionable in all inflammatory conditions of the digestive tube. In stercoreaceous vomiting, with other constitutional symptoms of hernia, but without local evidence of displacement, and where the stomach rejected the ordinary senna draught, I have known oil of croton prove most effectual. In torpid conditions of the intestinal canal, in tendency to apoplexy, in dropsy unconnected with inflammation, in paralysis—in a word, in any cases in which a powerful and speedy intestinal irritant is required, either for the purpose of evacuating the canal merely, or for acting as a revulsive or counter-irritant, and thereby relieving distant parts, croton oil is a very useful, and, on many occasions, most valuable cathartic. In employing it, two cautions are necessary: it must be avoided, or at least used with great caution, in extreme debility; and it is improper in inflammatory affections of the digestive organs. The great drawback to its use is its uncertainty. In one case it acts with extreme violence, in another it scarcely produces any effect. In the diseases of children, where a powerful purgative is required, croton oil has been administered, on account of the minuteness of the dose and the facility of its exhibition. In hydrocephalus, and other head

---

affections of children, I have several times used it where other cathartics have failed, or where extreme difficulty was experienced in inducing the patients to swallow the more ordinary remedies of this class. In some of these it has disappointed me. In the case of a child of four years of age, affected with incipient hydrocephalus, I gave six doses, of one drop each, of the oil without any effect. In uterine obstructions (chlorosis and amenorrhea) it has occasionally proved serviceable. In tapeworm it has been recommended, but I have no experience of its efficacy.

Rubbed on the skin, croton oil has been employed to produce rubefaction and a purgative eruption, and thereby to relieve diseases of internal organs, on the principle of counter-irritation, before explained (see vol. i. p. 170). Inflammation of the mucous membrane lining the air-passages, perijnymonia, glandular swellings, rheumatism, gout, and neuralgia, are some of the diseases against which it has been applied in this way; and doubtless frequently with benefit. It is sometimes used in the undiluted form, but more commonly with twice or thrice its volume of olive oil, oil of turpentine, soap liniment, alcohol, ether, or some other convenient vehicle. But, in all the cases just enumerated, it has never appeared to me to present any advantage over many other counter-irritants in common use—as emetic tartar; while the chance of causing purging is, in some cases, an objection to its use, and its greater cost sometimes precludes its employment on a large scale in pauper establishments. Frictions with it on the abdomen have been used to promote alvine evacuations, but it frequently fails to produce the desired effect. To promote the absorption of the oil in these cases, it should be dissolved in ether or alcohol, and the frictions are to be assiduously made.

ADMINISTRATION.—Croton seeds are rarely or never used in this country. Their farina may, however, be given in doses of a grain or two.

CROTONIS OLEUM, E.; Tiglii Oleum, L.; Oleum Tiglii, U.S.; Croton Oil.—This is the expressed oil of the seeds. It is imported from the East Indies, principally from Madras and Ceylon, but in part from Bombay. I have been informed by an oil-presser at Calcutta that it is prepared like castor oil, except that it is strained instead of being boiled. In shelling the seeds, the women often suffer severely with swelling of the face, &c. Croton oil is also expressed in England. The operation is usually effected by a Bramah's press in a room heated to about 75° F. The men engaged in the process are usually much affected by it; they suffer redness of the face, irritation of the eyes and air-passages, and purging. The following are the results obtained at two operations: the weights are avoirdupois:—

</table>

This gives a percentage produce of about 22.46. The colour of the oil thus obtained, when viewed by transmitted light, was that of dark sherry. No use is made of the cake.

In France, the croton cake is subjected to the action of alcohol, and the oil thus obtained mixed with the previously expressed oil. Guibourt obtained by expression 41.6 per cent. of oil from the kernels of the seeds, and subsequently 10.4 per cent. by the action of alcohol: making together 52 per cent. Calculating the shells at one-third the weight of the entire seeds, this product would be equal to nearly 35 per cent. for the entire seeds.

Genuine croton oil varies in colour from very pale yellow (like that of Canada balsam) to dark reddish-brown (like the deepest-coloured sherry). Its consistence is unctuous, and increases with age. It has an unpleasant but marked odour and
an acid taste, and leaves behind an acid sensation in the fauces. It reddens litmus, and is soluble in ether and in the fixed and volatile oils.

The following are the characteristics of the goodness of the oil according to the Edinburgh College:

When agitated with its own volume of pure alcohol and gently heated, it separates on standing, without having undergone any apparent diminution.

This statement is not correct, according to my observations. Pure croton oil expressed in London dissolves in alcohol (sp. gr. 0.796) without requiring to be "gently heated." The oil imported from the East Indies does, however, require to be heated with the alcohol to effect its solution. In the second place, separation does not take place, at ordinary temperatures, in the case of a mixture of English croton oil and alcohol. But by a low temperature, separation takes place on standing, but in that case the volume of oil is found to be slightly augmented. East India croton oil mixed with alcohol separates by repose: the volume of the oil, however, is increased and that of the alcohol proportionately lessened.

In one experiment, 8 vols. of E. I. croton oil were mixed with 8 vols. of alcohol, sp. gr. 0.796, and gently heated. In two days separation had taken place: the oil now measured $\frac{3}{4}$ vols., and the alcohol $\frac{7}{4}$ vols. In a second experiment, 7 vols. of another E. I. croton oil were mixed with 7 vols. of alcohol: in four days separation had taken place: the oil measured $\frac{7}{4}$ vols., and the alcohol $\frac{9}{4}$ vols.

According to Dr. Maclagan, only 96 per cent. of the oil separates. It is obvious, therefore, that commercial croton oils, believed to be genuine, are not uniform in their relation to alcohol.

According to Mr. Twining, there are two kinds of croton oil met with in commerce. One is dark yellow and thickish, the other is straw-coloured. The first is the most energetic. These oils, he thinks, may perhaps be obtained from different plants; the one from Croton Tiglium, the other from Croton Pavana.

The croton oils found in the London market are of two kinds; one exotic, imported from India and Ceylon—the other expressed in London. These differ both in their appearance and relation to alcohol.

a. Oleum Crotonis Exoticum; Foreign or East Indian Croton Oil; Pale Croton Oil.—This is imported from Ceylon and the continent of India. It is paler than London expressed oil. Some samples are very transparent and pale yellow, like Canada balsam. Others (the more usual sort) are of a pale amber colour. If equal volumes of East India oil and alcohol (sp. gr. 0.796) be shaken together, an opake milky mixture is obtained: but, if the heat of a spirit-lamp be applied, the mixture becomes transparent and uniform. By standing, however, for twenty-four hours, it separates into two strata: the lower one consisting of the oil which has taken up a small quantity of alcohol, and has, in consequence, become somewhat augmented in bulk, and the upper one, the oil, which has suffered a corresponding diminution in volume (see above).

b. Oleum Crotonis Anglicum; English Croton Oil; Dark Croton Oil.—The oil expressed from croton seeds in London is darker coloured than that usually imported from India. By transmitted light it is of a reddish-brown colour, like that of the deepest sherry, almost approaching to chestnut brown. By reflected light it has a greenish tinge. The dark colour of the oil may perhaps depend on some change which the seeds have suffered by keeping. After the oil has stood for a few months it is found to have deposited some white fat (margarine?). If equal volumes of alcohol (sp. gr. 0.796) and this oil be shaken together at ordinary temperatures, they form a uniform transparent mixture, and no separation takes place on standing for many weeks, unless the mixture be exposed to a low temperature. This fact, which was mentioned to me by Mr. Redwood, he has verified with various samples of croton oil expressed respectively by himself, by Mr. Morson, by Messrs. Herrings, and by Messrs. May and Co. I have verified it with a sample expressed by Messrs. Herrings. Exposure to artificial cold (as a freezing mixture) or to the atmosphere during a very cold night will cause a separation: the oil is then found to have slightly increased in bulk, and the alcohol to have suffered a corresponding diminution of volume.

On what, it may be asked, does this difference in the properties of the East Indian and English croton oils depend? Does it arise from some difference in the mode of preparation? Or is the East Indian oil contaminated with jatropha oil?

Dr. Christison observes, that croton oil is "not easily adulterated with the com-

1 Dierbach, op. cit.
mon fixed oils, with the exception of castor-oil, because this is the only common oil which possesses sufficient thickness to impart due unctuousity. Castor-oil may be detected by the test mentioned in the Edinburgh Pharmacopoeia. Absolute alcohol shaken with the adulterated oil will dissolve out the impurity, and thus lessen its volume; but no visible diminution is produced on pure croton oil. Five per cent. of castor-oil may be thus detected; but the application of heat, as recommended by the College, is unnecessary.” It is obvious, however, that this test is not applicable to English croton oil adulterated with castor-oil, both of which oils are soluble in the cold in alcohol.

If any fraud be practised in respect to croton oil, the adulterating ingredient is, I suspect, jatropha oil, which is less soluble in alcohol than croton oil.

Croton oil is exhibited in doses of one, two, or three drops. In some instances it is simply placed on the tongue—as in coma, tetanus, mania, &c.; or it may be taken in a teaspoonful of syrup. These methods of administering it are objectionable, on account of the acrid taste produced. The usual mode of employing it is in the form of pills, made with conserve of roses or bread-crumb. Some have employed it in the form of emulsion, flavoured with some carminative oil or balsamic substance; but the burning of the mouth and throat to which it gives rise is an objection to its use.

a. Tinctura Crotonis; Tincture of Croton.—This is prepared by digesting the seeds, or dissolving the oil in rectified spirit. Soubeiran’s formula is one drop of croton oil, and half a drachm of rectified spirit.

b. Sopo Crotonis; Croton Soap.—This is prepared with two parts of croton oil and one part of soap-boiler’s lye. It is, in fact, a crotonate of soda. A croton soap is sold by Mr. Morson, of Southampton Row, Russell Square. It may be used as a purgative, in doses of from one to three grains. It has been said that the alkali diminishes the acrimonious property of the oil without affecting its cathartic powers—a statement, however, which is highly improbable.

2. LINIMENTUM CROTONIS, D.; Croton Liniment.—(Croton Oil f³vii; Oil of Turpentine f³vii. Mix them with agitation, D.)—A croton liniment is frequently prepared by mixing one part of croton oil with four or five parts of olive oil. Rubbed repeatedly on the skin, it occasions redness and a pustular eruption. It is used as a counter-irritant.

ANTIDOTES.—In a case of poisoning by the seeds or oil, the first object is to remove the oil from the stomach. Mild, demulcent, and emollient drinks are then to be given. Alkaline substances have been recommended as chemical antidotes, but their efficacy is not proved. Full doses of opium will be requisite to check the diarrhoea. To relieve a failing circulation, ammonia and brandy may be given, and the warm bath employed.

130. CROTON ELEUTERIA, Swartz.—THE SEA-SIDE BALSAM OR SWEET-WOOD.

Sex. Syst. Monocot, Monadelphica.

(Cortex, L.—Cascarilla. Bark probably of Croton Eleuteria, and possibly of other species of the same genus, F.—The bark, D.)

HISTORY.—Great confusion has existed with regard both to Cascarilla or Eleutheria bark and the plant yielding it.

The bark is said to have been first noticed by Vincent-Garcias Salat, a Spaniard, in 1692. In the following year, Stisser, a German professor, gave a more extended notice of it, and states that he had some of it given him by a person of distinction,
at that time just returned from England, who told him that it was the custom in England to mix it with tobacco, in order to render it more agreeable for smoking.

By Dale1 and some other pharmacologists, it was thought to be cortex thuris, or frankincense bark, and by Geoffroy2 and others to be a species of cinchona bark. Its name cascariila (the diminutive of cascara, the Spanish name for the rind or bark of trees) is also a Spanish name for Peruvian bark.

In 1754, Catesby3 noticed and figured a plant, which, he said, grew plentifully on most of the Bahama Islands, and yielded Cascaria bark, or, as he called it, "The llatheria bark, La Chacricula." This plant is generally supposed to be the Croton Cascarilla, Linn. (C. lineare, Jacq.); and several reasons led me, at one time,4 to think that it might be the source of the cascarilla bark of the shops—an opinion also entertained by Dr. Wood;5 but Dr. Lindley6 adduced several reasons for believing that the Croton Eleuteria was the true species, as Drs. Wright and Woodville had already asserted; and the subsequent receipt, by Dr. Lindley, of specimens of the plant, from the Hon. J. C. Lees, Chief Judge in the Bahamas, has fully confirmed the accuracy of Dr. Lindley's opinion.7 "The plant," says Mr. Lees, "is scarcely known here by the name of Cascarilla, but is commonly called Sweet Wood Bark, and often Eleuthera Bark, because it is chiefly gathered on the island of Eleuthera. It is the only bark receiving the name of Cascarilla exported from the Bahamas, where the tree grows in abundance."

The Croton Cascarilla, Don, L. (C. Pseudo-China, Schiede), yields Copalchi (not Cascarilla) bark.

Sp. Char.—A small tree; leaves ovate, obtuse, entire, beneath silvery and densely downy; racemes axillary and terminal, compound; flowers subsessile, monoeious (Lindley).

Branches and twigs angular, somewhat compressed. Leaves stalked, alternate, with a short but obtuse point. Flowers monoeious, subsessile. MALES: petals whitish; stamens 10–12. Ovary roundish; styles 3, bifid; stigmas obtuse. Capsules roundish, minutely warty, not much bigger than a pea, with three furrows, 3 cells, and 6 valves.8

Hab.—The Bahama Islands, Jamaica.

Description.—Eleutheria or cascarilla bark (cortex eleuteriae seu cascarea, chaguerille vel schacharilla) is in the form of fragments, or quills, of about one or two, more rarely three or four, inches long; the fragments being thin, and usually curved both longitudinally and transversely, the quills varying in size from that of a writing pen to that of the little finger. The bark is compact, hard, moderately heavy, and has a short resinous fracture, not fibrous or splinterly, as in cinchona bark. Some of the pieces are partially or wholly covered with a whitish rugous epidermis, cracked both longitudinally and transversely. If a longitudinal section of the bark be examined by the microscope, cells are observed filled with an orange-red matter (oleo-resin?). The cortical layers are of a dull brown colour. The taste of this bark is warm, spicy, and bitter; its odour is peculiar, but agreeable. When burned, it evolves a pleasant odour (which has been compared by Pfaff to that of vanilla or amber when heated), on which account it is a constituent of fumigating pastilles.

Fée9 has enumerated no less than forty-three species of lichens found on this bark. With one exception (Parmelia perlata, which I have never seen on casca-rilla), every one of these lichens has an adherent, crustaceous, amorphous thallus.

---

1 Pharmacologia, 3rd ed. p. 346, 1737. Many of the synonyms for this bark given in Dale's work are erroneous.

7 Swartz, Fl. Ind. occ.
8 United States Dispensatory.
9 Essai sur Cryptogames, 1821.
A very common species is *Lecidea Arthonioides*, Fée; the thallus of which is very white, and the apothecia minute, round, and black.

**Commerce.**—It is imported from Nassau, in New Providence (one of the Bahamas Islands).

**Composition.**—Cascarilla bark was analyzed by Trommsdorff, who obtained from it the following substances: Volatile oil 1.65, bitter resin 15.1, gum and bitter matter with trace of chloride of potassium 18.7, woody fibre, 65.6. Meissner detected in the ashes of the bark the oxide of copper. Brandes has announced the existence of a peculiar alkaline substance (cascarillina).

1. **Volatile Oil of Cascarilla (Oleum Cascarillae).**—It possesses the odour and taste of the bark. Its sp. gr. is 0.938. Its colour is variable, sometimes being greenish, at others yellow or blue. It consists of two oils, one boiling at 344°, and which contains no oxygen (its formula probably being C,H,); the other less volatile and oxygenated. Nitric acid converts it into a yellow, pleasant smelling resin. By distillation with water the bark yields about 1-120th of its weight of this oil.

2. **Resin.**—Separated from the alcoholic tincture of the cascarilla by the addition of water. It is reddish brown; has a balsamic, slightly bitter, not astringent taste; and, when thrown on hot coals, evolves an agreeable odour.

3. **Extractive.**—Has a bitter, but not balsamic taste. Its watery solution reddens litmus, and is unchanged by either ferruginous solutions or tincture of nutgalls.

**Chemical Characteristics.**—The sesquichloride of iron deepens the colour of the infusion of cascarilla. The tincture of nutgalls causes turbidity, and at the end of twenty-four hours a very slight precipitate. A very concentrated alcoholic tincture deposits some resin on the addition of water.

**Physiological Effects.**—Cascarilla bark belongs to the aromatic bitters, before noticed (see ante, p. 244): that is, it produces the combined effect of an aromatic and of a moderately powerful tonic; but it does not possess any astringency. Some pharmacologists place it with aromatics, others with tonics. Cullen, though at one time uncertain as to which of these classes it belonged, ultimately classed it with the tonics. Krauss states that moderate doses give rise, in very susceptible, especially in sanguine subjects, to narcotic effects; but though I have frequently employed it, I never observed an effect of this kind. Mixed with tobacco, and used for smoking, it is said to cause giddiness and intoxication.

**Uses.**—Cascarilla has been employed as a substitute for cinchona; and although it is inferior to the latter in tonic and febrifuge qualities, its aromatic quality frequently enables it to sit easily on the stomach, without causing either vomiting or purging, which, in irritable affections of the alimentary canal, cinchona is apt to produce. In this country it is principally employed in those forms of dyspepsia requiring an aromatic stimulant and tonic. It is also used in cases of debility generally; and in chronic bronchial affections, to check excessive secretion of mucus. In Germany, where it is a favourite remedy, it is used in many other cases; such as low nervous fevers, intermittentis, the latter stages of diarrhoea, and dysentery.

**Administration.**—The powder may be given in doses of from ten grains to half a drachm; but it is a less agreeable form than the infusion.

1. **Infusion Cascarillae, L. E. D.; Infusion of Cascarilla.**—(Cascarilla Bark, bruised, 3/2s [3/4], D.); Boiling [distilled, L.] Water Oj [Oss, D.]. Macerate for two [one, D.] hours in a vessel lightly covered, and strain [through linen or calico, E.]. The product should measure about eight ounces, D.)—A light and aromatic bitter tonic. It is a good vehicle for acids and alkalis. The tincture of cascarilla is usually joined with it. Dose, from 1/2s to 3/4s.

2. **Tinctura Cascarillae, L. E. D.; Tincture of Cascarilla.**—(Cascarilla Bark, bruised [in moderately fine powder, E.], 3/5; Proof Spirit Oj). Macerate for seven [fourteen, D.] days, then express and filter, L. "Proceed by percolation or diges-

---

2. Ibid.
4. Heilmittelchrefter, 8, 401.
tion, as afterwards directed for tincture of cinchona," E.)—Generally employed as an adjunct to tonic and stomachic infusions. Dose, from f3j to f5j.

(Cortex Copalche vel Copalchi.)

This species of Croton was discovered by Schiede (Linnaea, Bd. iv. S. 211, and 579, 1829) between Plan del Rio and Puente in Mexico. A small variety (C. Pseudo-China var. minor) was found between Laguna Verde and Actopan. Both plants yield a bark very similar to that of cascarilla, and which is called in the apothecaries' shops of Jalapa quina blanca or copalche.

According to v. Bergen and v. Santen four serons of this bark were imported in 1817 into Hamburg from Cuba under the name of cascarilla de Trinidad. In 1827, more than 30,000 lbs. of it came along with cinchona bark from Peru to Hamburg, by way of Liverpool. Of this, 32 serons were shipped at Payta and 300 serons at Guayaquil. It was said to be a cinchona called copalche (quina dit copalchi). The Prussian Minister, v. Altenstein, received it from Mexico under the name of copalche.1 In 1825, Meradieu2 published an analysis of it; and stated that it was known in Mexico as copalchi or cortex amarus. He showed a sample of it to Humboldt, who suggested that it might be the produce of Croton suberosum, HBK.

I have met with two sorts of copalche bark in English commerce: —

1. Quilled Copalche.—Under the name of a new kind of cinchona bark I received copalche bark in the form of small thin quills, which in shape, size, and general appearance, resemble that kind of cinchona bark called by druggists "ash cinchona." In flavour, it closely resembles cascarilla bark; and in burning evolves a similar odour. It is the kind figured by Gobel and Kunze, and is doubtless the sort which the late Mr. Don mistook for genuine cascarilla bark. It might with propriety be called Mexican cascarilla. From genuine or Panama cascarilla it is distinguished by the length of the quils, their colour, and the absence of transverse cracks.

2. Corky Copalche Bark.—Under the name of copalche or chiquique bark, I have received a bark in coarser larger quills and twisted pieces covered with a very thick and much cracked corky coat. Its taste is very bitter. In burning, it evolves an aromatic odour. Is this the produce of Croton suberosum? Dr. Stark3 states that he received it from Chili under the name of naturi; and that at Santa Cruz it is known as chiquique.

Copalche bark has been analyzed both by Meradieu and Brandes. According to the latter chemist, 100 parts of the bark yield a yellow bitter extractive with malate 13.3, brown tasteless extractive obtained by potash 3.3, acrid aromatic soft resin 6.3, green resin 1.0, semi-resin 8.3, fat with green resin 1.1, wax with malate of lime 0.7, gluinos nitrogenous matter 33.3, albumen 8.7, malate of lime 3.3, oxalate of lime 4.1, phosphate of lime 1.4, sulphates and muriates 0.7, ligneous fibre 18.0, loss in water and volatile oil 6.2.

The medicinal properties of copalche resemble those of cascarilla bark. In Mexico it is used as a substitute for cinchona in the treatment of intermittents. It may be exhibited in powder, infusion, decoction, tincture, or spirituous extract, in the same doses as cascarilla. Dr. Stark says the infusion or decoction is best made by half an ounce of bark to a pint of water: the dose being a tablespoonful or small wineglassful. The tincture he prepares with an ounce of bark to one pint of proof spirit; the dose being one or two teaspoonfuls.

182. RICINUS COMMUNIS, Linn.—THE CASTOR-OIL PLANT, OR PALMA CHRISTI.

Sex. Syst. Monacia, Monadelphia.

(Oleum e semine calore aut vi comparatum, L.—Expressed oil of the seeds, E.—The seeds from which the oil is expressed; Oleum ricini, D. [U. S.])

History.—The castor-oil plant was known in the most ancient times. Caiaux found the seeds of it in some Egyptian sarcophagi, supposed to have been at least 4000 years old.4 Whether this is, as some persons imagine,5 the plant called kikayon in the Bible,6 and which, in our translation, is termed the gourd, I cannot pretend to decide. The pious fathers, Jerome and Augustin, differed so much in

their opinions as to what was the particular plant meant in the passage just referred to, that from words we are told, they proceeded to blows.1

The ancient Greeks were acquainted with the *ricinus*, for both Herodotus2 and Hippocrates3 mention it; the latter employed the root in medicine. Dioscorides4 calls it the *χίλις* or *χριότυβον*. It was termed *χριότυβον* by the Greeks, and *ricinus* by the Romans,3 on account of the resemblance of its seeds to a little insect bearing these names, which infest dogs and other animals, and whose common name in English is the *tick*.

**BOTANY. Gen. Char.** — *Flowers* monocious. *Calyx* 3—5-parted, valvate. *Petals* 0. *Filaments* numerous, unequally polyadelphous; cells of the *anther* distinct, below the apex of the filament. *Style* short; *stigmas* 3, deeply bipartite, oblong, coloured, feathery; *ovary* globose, 3-celled, with an ovule in each cell. *Fruit* generally prickly, capsular, 3-ocious, with 1 seed in each cell. — *Trees, shrubs, or herbaceous* plants, sometimes becoming arborecent. *Leaves* alternate, palmate, peltate, with glands at the apex of the petiole. *Flowers* in terminal panicles, the lower male, the upper female; all articulated with their peduncles, and sometimes augmented by bi-glandular bracts (Lindley, from Endlicher).

The *stems* of plants growing in this country are round, greenish or reddish-brown, and blue pruinose, and branched. *Leaves* on long round petioles, 8- or 10-lobed. A large sessile or ovate acuminate, serrated. *Flowers* in long glaucous racemes. *Stigmas* 3, bifid at the apex. *Capsule* covered with spines.

**Hab.** — India. When cultivated in Great Britain, *Ricinus communis* is an annual, seldom exceeding three or four feet high; but in other parts of the world it is said to be perennial, arborecent, and to attain a height of fifteen or twenty feet. Dr. Roxburgh5 says that in India several varieties are cultivated, “some of them growing to the size of a pretty large tree, and of many years’ duration.” Clusius6 saw it in Spain with a branch.

ed trunk as thick as a man’s body, and of the height of three men. Belont 1 also tells us that in Crete it endures for many years, and requires the use of ladders to mount it. Ray 2 found it in Sicily as large as our common alder trees, woody, and long-lived; but it has been a question with botanists whether these arborescent and other kinds are mere varieties of, or distinct species from, the ordinary Ricinus communis.

The following (varieties or distinct species) are enumerated by Nees and Ebermayer 3 as common in gardens, and as distinguished principally by the colour and pruinose condition of the stem—characters which, however uncertain in other cases, appear here to be constant.

1. **Ricinus africanus** (Willd.).—Stem not pruinose, green, or on one side reddish. The fruit-racemes abbreviated, the fruit-stalk longer than the capsule. Seeds attenuated on one side, marbled gray and yellow-brownish.

2. **Ricinus macropetalus** (H. Berol.).—Nearly allied to the foregoing: stem quite green, not pruinose. Fruit-stalk as long as the fruit. The unripe fruit and prickles almost quite white.

3. **Ricinus lividus** (Willd.).—Stem pale green, white pruinose. Fruit-stalk as long as the fruit.

4. **Ricinus leucocarpus** (H. Berol.).—Stem, petiole, midrib purple red, not pruinose. Nearly allied to **R. africanus**, and, like this, more woody and perennial.

5. **Ricinus viridis** (Willd.).—Stem pale green, blue pruinose, by which it is distinguished from **R. macrophyllus**. Seed somewhat smaller, more oval, marked with white and fine brown. [Herbaceous. Cultivated in Bengal (Hamilton).]

**DESCRIPTION.**—Castor seeds (seminia ricini seu sem. cataputiae majoris) are oval, somewhat compressed, about four lines long, three lines broad, and a line and a half thick; externally they are pale gray, but marbled with yellow-brown spots and stripes. The seed-coats consist, according to Bischoff, 4 of a smooth external coat (epidermis seminalis). 2dly, a diffusum, hard testa, consisting of two layers—an external thick and dark brown one, and an internal one, thinner and paler. 3dly, a cuticula nuclei or membrana interna. The fleshy tumid cicatricula stomaticis (also termed strophiola) is very evident at the upper end of the seed; beneath it is a small hilum, from which passes downwards the longitudinal raphé. 5 The chalaza is colourless. 7 The nucleus of the seed consists of oily albumen and an embryo, whose cotyledons are membranous or foliaceous.

**COMPOSITION.**—The only analysis of these seeds, as yet published, is that of Geiger. 6 The following are his results:—

1. **Volatilize Acid Principle (? ricinoleic acid).**—This principle is not mentioned by Geiger, and its existence has been doubted or denied by others. But the following as well as other facts establish, in my opinion, its presence: First, Guibourt 8 experienced a peculiar feeling of dryness of the eyes and throat, in consequence of having been exposed to the vapour arising from a vessel in which bruised castor seeds and water were boiling. Secondly, Planche obtained a permanent odorous principle by distilling a mixture of water and castor-oil. Bussy and Lecomte 9 ascribe the occasional acridity of the oil to the production of fatty acids, by the action of the air on it.

2. **Fixed Oil.**—(See Olum Ricini.)

3. **Acrid Resin.**—Castor seed appear to contain a fixed acrid principle, probably of a resinous nature, as suggested by Soubeiran. 10 The acrid principle (whatever its nature may be) appears to reside in both the **albumen** and **embryo** of the seeds. Jussieu 11 and some others have asserted that it resided exclusively in the embryo; while Brotton-Charlard and Henry, jun. 12 declared the albumen to be the exclusive seat of it. But any unprejudiced person may soon

satisfy himself, by tasting separately the embryo and albumen, that both parts possess acridity. Dierbach statements that in fresh seeds the innermost seed-coat contains the acrid principle. If this be correct, it is most remarkable that the same coat, when dry, contains none.

Calhoun found that castor cake (the residual cake left after the expression of the oil from the seeds), after having been deprived of all its principles soluble in alcohol, still contains an acrid principle, and excites vomiting when given in doses of about 7/ grains.

**Physiological Effects.**—Castor seeds possess considerable acridity. Bergius states that a man masticated a single seed at bedtime; the following morning he was attacked with violent vomiting and purging, which continued the whole day. Lanzoni also states that the life of a woman was endangered by eating three grains of the seeds. More recently, a girl, 18 years of age, was killed by eating "about twenty" seeds: the cause of death was gastro-enteritis.

**OLEUM RICINI, L. E. D.: Castor-Oil.**—This may be obtained from the seeds by expression, by decoction, or by the agency of alcohol. The chief part, if not the whole of the oil consumed in England, whether imported or extracted in England, is procured by expression.

Soubeiran considers all processes in which heat is employed as objectionable, as a quantity of fatty acids is produced which renders the oil acrid. In America, on the contrary, heat is considered useful by expelling a volatile acrid principle. It cannot be doubted but that too high a temperature develops acrid matter. In England, the oil is expressed, either by Bramah's hydraulic press, or by the common screw-press, in a room artificially heated. It is purified by rest, decantation, and filtration. It is bleached by exposure to light on the tops of houses.

In Calcutta, it is prepared as follows: The fruit is shelled by women; the seeds are crushed between rollers, then placed in hempen cloths, and pressed in the ordinary screw or hydraulic press. The oil thus procured is afterwards heated with water in a tin boiler until the water boils, by which the mucilage or albumen is separated as a scum. The oil is then strained through flannel and put into canisters. The castor seeds are distinguished according to the country yielding them. Two principal kinds are known, the large and the small nut; the latter yields the most oil. The best East Indian castor-oil is sold in London as cold drawn.

In the Southern provinces of India, according to Ainslie, castor-oil is obtained by decoction. Much of the American castor-oil is prepared by mere expression, rest, and decantation; but the following are the outlines of the process usually employed in the United States by those who prepare it on the large scale. The seeds, cleansed from the dust and fragments of the capsules, are placed in a shallow iron reservoir, where they are submitted to a gentle heat insufficient to search or decompose them, and not greater than can be readily borne by the hand. The object of this step is to render the oil sufficiently liquid for easy expression. The seeds are then introduced into a powerful screw-press, and submitted to pressure, by which a whitish oily liquid is obtained, which is boiled with a considerable quantity of water in clean iron boilers, and the impurities skimmed off as they rise to the surface. The water dissolves the mucilage and starch, and the heat coagulates the albumen, which forms a whitish layer between the oil and water. The clear oil is now removed, and boiled with a minute portion of water until aqueous vapour ceases to arise, and till a small portion of the liquid taken out in a phial preserves a perfect transparency when it cools. The effect of this operation is to clarify the oil, and to render it less irritating by driving off the volatile acrid matter. But much care is requisite not to push the heat too far, lest the oil acquire a brownish hue, and an acrid peppery taste similar to the West India medicine. One basket of the seeds yields five or six quarts, or about twenty-five per cent, of the best oil.

In the West Indies the oil is obtained by decoction; but none of it comes to this country in the way of commerce. In Jamaica, the bruised seeds are boiled with water in an iron pot, and the liquid kept constantly stirred. The oil, which separates, swims on the top, mixed with a white froth, and is skimmed off. The skimnings are heated in a small iron pot, and strained through a cloth. When cold, it is put in jars or bottles for use. The object of the second heating is to dissipate the volatile acrid principle; but if the process be not suspended immediately after the water is driven off, the oil acquires a reddish-brown colour, an acrid flavour and irritating qualities. It is said that the seeds are sometimes roasted to increase the product. By this process also the oil is coloured and rendered acrid.

In Armenia, the oil is obtained by decoction; in Russia, by expression.

On the continent of Europe, castor-oil is sometimes obtained by the agency of alcohol. The process is more expensive, and the product is inferior.

5. Private information from an oil-presser of Calcutta.
7. United States Dispensatory.
VEGETABLES.—NAT. ORD. EUPHORBIACEA.

The oleum ricini alcoholicum, in use in Italy, is apparently an alcoholic extract, composed of 72 per cent. of oil and 28 per cent. of alcohol and water. The dose is from half an ounce to an ounce.

Properties.—Castor-oil is a viscid oil, usually of a pale yellow colour, with a slightly nauseous odour and a mild taste. It is lighter than water, its sp. gr. being, according to Saussure, 0.969 at 55° F. When cooled down to about 0°, it congeals into a transparent yellow mass. By exposure to the air it becomes rancid, thick, and ultimately congeals, without becoming opaque; and hence it is called a drying oil. When heated to a little more than 500° F. it begins to decompose.

Solubility.—Castor-oil is remarkable for its ready solubility in alcohol. Strictly speaking, castor-oil and alcohol exercise a mutual solvent action on each other. When they are shaken together, an homogeneous transparent mixture is obtained. Rectified spirit of wine may be substituted frequently with a similar result; but with some samples of genuine oil the mixture does not become clear until heat is applied; and moreover by standing a separation takes place into two strata, an upper spirituous one holding oil in solution, and an inferior oleaginous one containing spirit. In one experiment, 65 vols. of oil and 65 vols. of rectified spirit were mixed, and by shaking a transparent uniform mixture was obtained: after several weeks a separation had taken place: the upper stratum measured 12 vols., the lower one 118 vols. Of three samples of genuine oil, one English, a second West Indian, and the third East Indian, I find the English to be the most, and the East Indian the least soluble in rectified spirit.—I find that castor-oil enables other fixed oils (olive, nut, lard, and other oils) to dissolve in alcohol. Thus, if one vol. of olive oil, 2 vols. of castor-oil, and 2 vols. of rectified spirit be mixed and heated, a transparent homogeneous solution is obtained.—Ether readily dissolves castor-oil.

Varieties.—In the London market there are chiefly three sorts of castor-oil; namely, the oil expressed in London from imported seeds, East Indian oil, and the American. West Indian and Australian oils are rarely to be met with.

1. English Castor-Oil.—By this is meant castor-oil drawn in England from imported seeds. It differs somewhat from the imported oil. I am informed that it never bleaches so completely by exposure to light as the East Indian oil. This is usually ascribed to the seeds having suffered some change before they are pressed. But something is probably due to the mode of preparation: in England the oil is not heated in boiling water, as it is in Calcutta.

2. East Indian Castor-Oil is the principal kind employed in this country. It is imported from Bombay and Calcutta. It is an oil of exceedingly good quality (both with respect to colour and taste), and is obtained at a very low price. It is procured from Ricinus communis and R. latifolia. I am informed that occasionally it solidifies by keeping.

3. American or United States Castor-Oil is, for the most part, imported from New York. All the samples which I have examined have been of very fine quality, and, in my opinion, had a less unpleasant flavour than the East Indian variety. Our druggists object to it, on the ground of its depositing a white substance (margarine) in cold weather—a circumstance which has led some persons to imagine it had been mixed with some other fixed oil (lard oleine?).

4. West Indian Castor-Oil.—For an authentic specimen of this oil I am indebted to Mr. Spencer, of Lamb's Conduit Street, who received it some years since from the wife of the Governor of the Island of Tobago, on whose estate it was procured. Its colour is that of golden brown sherry.

5. Australian Castor-Oil.—Of this I have seen but one sample, which was dark coloured.

Commerce.—Castor-oil is imported in casks, barrels, hogheads, and duppers. The latter are made, as I am informed, of gelatin (prepared by boiling the cuttings of skin) moulded in earthen moulds. In this country the oil is purified by decantation and filtration, and is bleached by exposure to solar light on the tops of houses.

Composition.—The following is the ultimate composition of castor-oil, according to the analyses of Saussure and Ure:

2 According to Stoltze, benzoic acid augments the solubility of castor-oil in spirit containing 75 per cent. of alcohol; that is, in spirit whose sp. gr. is 0.860. Camphor has a similar influence.
The proximate principles have not been accurately determined. From Bussy and
Lecanu’s 1 researches we may infer that castor-oil contains three fats, each composed of
oxide of glyceryle and a fatty acid. But according to the more recent investiga-
tions of Saalmuller, 2 there can be but two fats in this oil. In addition to these
fats there is probably a small proportion of an acidic resin. The following table,
therefore, represents the

**Presumed Composition of Castor-Oil.**

| Ricinoleine. |
| Margaritine. |
| Acid resin? |

1. **Ricinoleine.**—This has not been isolated. It is the constituent of castor-oil which by
saponification yields oxide of glyceryle and a liquid acid, the ricinoleic acid, C18H36O3. Bussy
and Lecanu regard this acid as a mixture of two acids, which they term ricinin and elaidinic acids.

2. **Margaritine; or Ricino-stearine.**—This is a solid, white crystalline fat which separates from
castor-oil in cold weather. By saponification it yields oxide of glyceryle and a solid crystalliz-
able fatty acid called margaritic acid, in its melting point (162° E) and composition ex-
hibits a great resemblance to stearic acid, C22H44O2. But with a margaritic acid obtained from
another sample of castor-oil, he found the composition to approach more to that of palmitic
acid, C36H70O2.

According to Lecanu and Bussy, margaritic acid constitutes only 0.002 of the products of
saponification of castor-oil: it follows, therefore, that the proportion of margaritine in the oil
must be small. But it is probable that the quantity is variable, and that the differences observed
in the action of alcohol in the different specimens of castor-oil depend on variations in the rela-
tive proportions of the margaritine and ricinoleine.

3. **Acid Resin?**—Some years since, Soubeiran 3 obtained from castor-oil by a complicated pro-
cess what he supposed to be a soft resinous oil, but which was evidently a complex product.
To this he in part ascribed the purgative qualities of castor-oil.

**Products of decomposition.**—By saponification and distillation castor-oil yields certain
peculiar products by which it is characterized.

</table>

1. **Cenanthal.**—Described by Bussy and Lecanu as volatile oil; but more recently by Bussy 4 as
cenanthal. It is a colourless limpid aromatic liquid, whose formula is C14H10O. It is scarcely
soluble in water, but dissolves in alcohol and ether. It rapidly oxidizes in the air, and becomes
elainolic acid (C14H14O3). It combines with water, forming a crystalline hydrate, C14H14
O3. By the action of nitric acid it yields a low temperature an isomeric compound called
metenanthal; and at a high temperature, besides elainyl and other volatile fatty acids, a
volatile oil resembling oil of cassia.

2. **Solid residuum of distillation.**—Pale, yellow, elastic, spongy, having the consistence of soft
new bread, gelatiniform, odourless, tasteless, combustible, solid. It is insoluble in alcohol, ether,
and the oils (both fixed and volatile).

By the action of hyponitric acid on castor-oil Boudet obtained a solid odorous fat called
palmine, which, by saponification, yielded palmine acid, C34H603, and glycerine; and by the action of nitric acid on castor-oil, Mr. Tilley 5 obtained
elainyllic acid.

**Adulteration.**—Two kinds of frauds have been practised with regard to castor-oil.

One consists in the admixture of a small quantity of croton oil to it, with the
view of increasing its activity. This mixture is introduced into gelatine capsules,
and sold as concentrated castor-oil. This fraud is a very dangerous one. I have

1 *Journal de Pharm.*, t. xiii. p. 57, 1827.
3 *Journal de Pharm.*, t. xv. p. 567, 1829.
heard of several cases in which very violent and dangerous effects were produced by these capsules on pregnant females.

The other fraud consists in the adulteration of the castor-oil with some bland viscid cheaper oil. I have been informed that the oleine of lard, called lard oil, has been used for this purpose, but I have not been enabled to procure evidence of it. This kind of fraud is said to be detected by alcohol, which dissolves the genuine castor-oil, but not the admixed oil; and accordingly, in the Edinburgh Pharmacopoeia, the test of the purity of the oil is that "it is entirely dissolved by its own volume of alcohol." Unfortunately, however, for this test, castor-oil may be adulterated with 33 per cent. of another fixed oil, and yet be soluble in its own volume of alcohol.

**Physiological Effects.**—a. *On Animals generally* castor-oil acts as a laxative or mild purgative. Large animals, as the horse, require a pint or more for a dose; smaller ones need only a few ounces. Mr. Youatt, however, declares this oil to be both uncertain and dangerous in the horse.

β. *On Man.*—Injected into the veins castor-oil gripes and purges, and causes a nauseous oily taste in the mouth; hence it would appear to have a specific influence over the mucous lining of the alimentary canal. Swallowed to the extent of one or two ounces, it usually acts as a mild but tolerably certain purgative or laxative, without producing any un easiness in the bowels. It has this particular advantage," says Dr. Cullen, "that it operates sooner after its exhibition than any other purgative I know of, as it commonly operates in two or three hours. It seldom gives any griping, and its operation is generally moderate—to one, two, or three stools only." It not unfrequently occasions nausea, or even vomiting, especially if somewhat rancid; in many cases, I believe, rather from its disgusting flavour than from any positively emetic qualities.

It has been stated by continental writers that castor-oil is most unequal in its action, at one time operating with considerable violence, at another with great mildness; but I have never found it so, nor is it usually considered to be so in this country. I can, however, readily believe that a difference in the mode of its preparation, especially with reference to the heat employed, may materially affect its purgative property.

When castor-oil has been taken by the mouth, it may be frequently recognized in the alvine evacuations; but it presents itself under various forms, "sometimes resembling caseous flakes, or a soap-like scum, floating on the more fluid part of the defecation: occasionally it had been arranged in a form not unlike bunches of grapes, or more nearly of hydatids of a white colour; more generally, however, it is found mixed up with the feces as a kind of emulsion, and in some few instances it has been discharged under the form of solid tallow-like masses." Dr. Brandt says in one case it was discharged from the bowels in the form of indurated nodules, which were at first regarded as biliary concretions. A remarkable case is mentioned by Dr. Ward, of a woman on whom this oil does not act as a purgative, but exudes from every part of her body.

*Uses.*—Castor-oil is used to evacuate the contents of the bowels in all cases where we are particularly desirous of avoiding the production of abdominal irritation (especially of the bowels and the urino-genital organs). The principal, or I might say the only objection to its use in these cases, is its nauseous taste. The following are the leading cases in which we employ it:

1. *In inflammatory affections of the alimentary canal,* as enteritis, peritonitis, and dysentery, a mild but certain purgative is oftentimes indicated. No substance, I believe, answers the indication better, and few so well, as castor-oil.

2. *In obstructions and spasmodic affections of the bowels,* as intussusception, ileus, and colic, especially lead colic, this oil is the most effectual evacuant we can employ.

---

3. Dr. E. Hare, in *Begin’s Traité de Thérapeutique*, p. 111.
3. After surgical operations about the pelvis or abdomen (for example, lithotomy, and the operation for strangulated hernia), as well as after parturition, it is the best and safest purgative.

4. In inflammatory or spasmodic diseases of the urino-genital organs, inflammation of the kidneys or bladder, calculous affections, gonorrhoea, stricture, &c., castor-oil is a most valuable purgative.

5. In affections of the rectum, especially piles, prolapsus, and stricture, no better evacuant can be employed.

6. As an antihelmintic for tape-worms, castor-oil was first employed by Odier. Arnemau, however, has shown that it possesses no peculiar or specific vermifuge properties.

7. As a purgative for children, it has been used on account of its mildness, but its unpleasant taste is a strong objection to its use.

8. In habitual constiveness, also, it has been recommended. Dr. Cullen observed that, if castor-oil be frequently repeated, the dose might be gradually diminished; so that persons who, in the first instance, required half an ounce or more, afterwards needed only two drachms.

Administration.—The dose of castor-oil for children is one or two teaspoonfuls; for adults, from one to two or three tablespoonfuls. To cover its unpleasant flavour, some take it floating on spirit (especially gin), but which is frequently contra-indicated; others on coffee, or on peppermint or some other aromatic water; or it may be made into an emulsion by the aid of the yolk of egg or mucilage of tragacanth.

133. Curcas Purgans, Adams; and C. multifidus, Endlicher.—

Physic Nuts.

(Semina.)

The seeds and bulbs of both these species of Curcas are met with under the name of physic nuts; and as their effects and uses are similar, I include them under a common head.

Gen. Char.—Flowers monocious. Calyx very short, 5-parted. Males: Corolla globose-campanulate, 3-cleft. Stamens 10, united at the base, the 5 exterior alternating with the same number of conoid glands; filaments filiform; anthers turned inwards, 2-celled. Females: Corolla much larger than the calyx, convolute; consisting of 5 petals. Ovary on a 5-lobed disk, 3-celled, with 1 ovule in each cell. Styles 3, filiform, distinct. Stigmas thick, 2-celled. Capsule 3-cocconis, with 1 seed in each cell.—Tropical shrubs of America. Leaves alternate, petiololed, angulate-5-lobed, quite entire, truncated at the base, reticulate-5-nerved, quite smooth. Corolla with long peduncles; the males terminal; the females axillary (Endlicher).

Species.—1. Curcas Purgans, Adams; Jatropha Curcas, Linn.; English Physic Nut, Wright; Physic-nut tree, Hughes; Browns; Angular-leaved Physic Nut, Miller; Pinheiro de purga, Pinhão paraguaia, Mart., Syst. Mal. Med. Brasil.—Leaves long-stalked, broadly cordate, angular, roundish; panicles terminal or axillary, in cymes.—West Indies; Brazil; Coast of Coronandel; Ceylon.

The fruit is a trioccous capsule about the size and shape of a walnut.

The seeds (semina curcadi), sometimes called American or English physic nuts, or simply physic nuts (nuces cathartica americana), Barbados seeds or nuts (nuces barbadenses), semina ricini majoris or gros pignon d’Inde, have the shape of castor seeds, but are somewhat rough to the touch, and black, but marked with numerous minute cracks. The kernels are covered with a fine white pellicle (cuticula nuclei). The seeds have been analyzed by Cadet de Gassicourt1 and by Soubeiran.2 The latter chemist found in them a fixed oil, a peculiar fixed acid renn, saccharine matter, gum, a small quantity of fatty acid, gluten (emulsin?); a free acid (male?), and some salts.

The expressed oil, commonly called jatropha oil (oleum jatrophae curcadi vel oleum infernalis), was imported a few years ago under the name of oil of wild castor seeds. It is sometimes expressed in England. As commonly met with, it has a yellowish colour, with a feebie colour, and during the cold weather deposits a white solid fat (margarine or stearine). When fresh and pure it is described as being colourless, colourless, and quite limpid. 1000 parts of the seeds yielded Guiouco 656 parts of kernels, from which he obtained 265 parts of a colourless very fluid oil, which in the cold deposited a considerable quantity of stearine. Jatropha oil differs from castor and croton oils in its slight solubility in alcohol; but mixture with castor-oil

1 Journa. de Pharm. t. x. p. 176, 1824.
2 Ibid. t. xv. p. 503, 1829.
augments its solubility. According to Mr. Quettet,1 it is well adapted for burning in lamps; for purpose which it is employed in India.

Jatropha seeds and oil resemble the seeds and oil of croton in the character of their effects. Mr. Bennett2 swallowed four seeds, and experienced a very unpleasant sensation in the stomach and bowels, with nausea, which, after an interval of nearly two hours, terminated in vomiting; their purgative effects followed soon afterwards, and were mild; the sickness had then passed away, but the burning sensation continued for some time longer. The kernels of five seeds caused in a labourer vomiting, purging, perspiration, delirium, giddiness, and delirium. Four hours after taking the poison he walked to the London Hospital: the pupils were natural, the countenance pale, the hands cold, and the pulse 140. An opiate and a mild cordial were given to him, and he soon recovered.3 Jatropha oil is occasionally used as a drastic purgative. It is less powerful than croton oil. Dr. Christie states that twelve or fifteen drops of it are about equal to one ounce of castor-oil. The residual cake from which the oil has been expressed is very active. The last-mentioned authority found that a few grains of it caused violent vomiting and purging. The juice of the plant4 has been successfully applied externally as a remedy for piles. Dr. McWilliam5 says, that a decoction of the leaves is used by the natives of the Cape Verde Islands to excite a secretion of milk in women who have borne a child, and who are not past child bearing.

2. CURCAS MULTIFIDUS, Endlicher, Enchir. Botan.; Jatropha multifida, Linn.; Adenorrhœum multifidum, Pohl; French Physic Nut; Spanish Physic Nut.—Leaves large, stalked, palmate or digitate, many lobed, smooth; lobes pinnatifid, cuneate.—West Indies; Brazil.—The capsule is yellowish, about the size of a walnut, oblong, 3-cornered, somewhat tapering above, 3 celled; each cell containing 1 seed. The seeds, called French physic nuts (semina curcadis multifidi; nucex purgantes; avalana purgatrices; ben magnum), are about the size of those of a common nut, rounded externally, with two flattened surfaces separated by an ovule internally. The seed coat is marbled and smooth; the kernel is white.—The composition of these seeds is, according to Soubeiran,6 similar to that of the seeds of the Curcas purga.—The expressed oil (oleum curcadis multifidi; oleum pinhoen), as well as the seeds, are drastic cathartics. In their operation they resemble the preceding oil and seeds. Death is said to have been produced by them.7

3. The seeds of the Jatropha Gossypifolia, Linn.; Bastard French Physic Nut, Belly-ache, or Wild Cassava, have also been used as purgatives in dropsies.8

183. ANDA BRASILIENSIS, Raddi. (Semin.)

Anda, Piso, l. 72; II. 148; Anda brasiliensis, Raddi, Quarante piante, &c. 1821; Anda Gomezii, Ad. Jussieu, De Euphorb. Generib. 1824; Anda-agu, Indayagu, Purga de Genio; Cocoe de Purga, Purga dos Paulistas, Frutta d'Arara, Brazil.—Brazil.—The fruit is about the size of an orange, with 2 large and 3 smaller angles. It contains two roundish nut-like seeds (semina anda brasiliensis) about the size of small chestnuts. By pressure they yield a fixed oil (oleum anda brasiliensis; oil of anda-agu). Both seeds and oil are purgative. One seed, according to Von Martin,9 is a dose for a man. The expressed oil is clear and pale yellowish. Like jatropha oil, it is not very soluble in alcohol; but its solubility is increased by the addition of castor-oil. Mr. Ure10 found that in doses of 20 drops it operated moderately as a purgative.

184. MANIHOT UTILISSIMA, Pohl.11—BITTER CASSAVA. (Sect. Syst. Monacæa, Monadelphia. (Fecula of the root; Tapioca, E. D. [U.S.])

HISTORY.—Monardes12 describes the Indian method of making cassava bread; and Piso13 notices the mode of preparing the farina called cream of Tapioca [Tapioca].

BOTANY. Gen. Char.—Flores monœcious. Calyx corolline, campanulate, 5-cleft, convolute. Corolla 0. Stamens 10, inserted on the margin of a fleshy

5 Report on the Boa Vista Fever, 1847.

12 De Medicina Brasilii. p. 92.
Bitter Cassava.—Description; Composition.

381
disk, free, the alternate ones shorter: filaments filiform; anthers turned inwards, 2-celled. Ovary placed on the fleshy disk, 3-celled, with 1 ovule in each cell. Style short. Stygias 3, many-lobed, the lobes consolidated into a conical sinuated-sulcate mass. Capsule 3-coccous; the cocci 2-valved and 1-seeded (Endlicher).

Sp. Char.—Leaves with very long petioles, deeply 7-parted, palmate; the segments lanceolate, acuminate, attenuated at the base, quite entire, the outer ones smaller, unequal, diverging, straggling. Root whitish-yellow (Pohl).

Root large, thick, tuberous, fleshy; containing an acid, milky, highly poisonous juice. Flowers axillary, racemose.1

Hab.—Native of the Brazil; where, as well as in other parts of South America, it is cultivated.

Manihot Api, Pohl.—Sweet Cassava, Bancroft, Nat. Hist. of Guiana, 1769.—This is usually regarded as a variety of the above; but Pohl considers it to be a distinct species; characterized by the leaves which are 5-parted, and by the root, which is reddish, and contains a milky non-poisonous juice. It is cultivated in the Brazils, and in Spanish America.

Manihot Janipha, Pohl; Jatropha Janipha, Linn.; Janipha Loebigii, HBK.—This species is said to yield the sweet or white cassava of the West Indies. Dr. Hamilton2 says it so closely resembles the Janipha Manihot, Linn. (Manihot utilissima, Pohl), that an experienced eye can hardly distinguish it with certainty. Is not the sweet cassava of the West Indies the Manihot Api of Pohl? Like the latter, it is devoid of poisonous properties.

Description.—1. Bitter cassava root is a large tuberous root3 which abounds in a poisonous milky juice. It is difficult to distinguish by its appearance from the sweet cassava root; but it is devoid of the tough, fibrous, or woody filaments found in the heart of the sweet cassava root; and it does not become soft, like the latter root, by boiling or roasting. The rasped root mixed with water, boiled, and then fermented, yields a spirituous liquor called cassiri.4 Cassava meal is obtained by subjecting the grated root to pressure to express the juice, and then drying and pounding the residual cake. Of this meal cassava bread is made. The expressed juice by repose deposits the farina called cassava starch, of which tapioca is made. A sauce called casarreo or cassireepe, is made from the juice.5

2. Sweet cassava root resembles the bitter cassava root in external appearance; but, unlike the latter, it is not poisonous. It has a bundle of tough, fibrous, or woody filaments at the heart, running longitudinally through the root. By boiling or roasting it becomes soft, and is used at table.

A few pounds of dried sweet cassava root have recently been sent to England from Jamaica on speculation, to ascertain whether it was likely to prove a profitable article of commerce. It consisted of transverse and longitudinal segments, which were beautifully white, had a very faint agreeable odour, and were meiilaginous or farinaceous to the taste. The circular disks were from one to two or more inches in diameter, and had in the centre the ligneous cord above alluded to. Some of the pieces were worm-eaten: a few were slightly scorched or burnt, apparently by over-heating in the drying process.

Cassava meal and bread, cassava starch, and tapioca, are prepared from the sweet as well as from the bitter cassava root.

Composition.—The bitter cassava root has been analyzed by MM. O. Henry and Boutron-Chalard,6 who inferred that it contained free hydrocyanic acid, starch, a small quantity of sugar, an organic salt of magnesia, a bitter principle, a crystallizable fatty matter; an azotized matter (vegetable osmazome), phosphate of lime, and woody fibre.

1 Hooker, Bot. Mag. t. 9071.
3 A figure of the root is given in the Journ. de Pharm. t. xxii. 1831.
5 Cassireep is the concentrated juice of the roots of the bitter cassava flavoured by aromatics. During the evaporation, the poisonous principle of the juice is either dissipated or destroyed. Changeep is used to flavour soups and other dishes; and is the basis of the West Indian dish pepper-pot. It is a powerful antiseptic (Shier, Report on the Starch-producing Plants of the Colony of British Guiana, Demerara, 1817; Hamilton, Pharmaceutical Journal, vol. v. p. 30, 1845).—In French Guiana, the term cassiow or casin is applied to a similar condiment (Henry and Boutron-Chalard, Journ. de Pharm. t. xxii. p. 193). The inapissated juice flavoured with capsicum pods is used in the Brazil as a sauce, under the name of Tympé or Turep (Martius, Spat. Nat. Med. Veg. Brasilii, p. 94).
6 Journ. de Pharm. t. xxii. p. 112, 1836.
1. HYDROCTANIC ACID.—According to O. Henry and Boutron-Chalard, the active principle of the root is hydrocyanic acid. Their statement is confirmed by Dr. Christison, who examined some well-preserved juice from Demerara.

2. VOLATILE ACID PRINCIPLE.—The vomiting and purging, and other abdominal symptoms ascribed to bitter cassava, would lead us to suspect that, like other euphorbiaceous plants, it contains an acrid principle.

PHYSIOLOGICAL EFFECTS.—The fresh roots as well as the expressed juice are virulent poisons, destroying life in a very short period of time. O. Henry and Boutron-Chalard described the effects on guinea-pigs as resembling those caused by hydrocyanic acid; but death did not occur until from forty to fifty-five minutes after the use of the poison. Ricord Madianna has killed dogs in ten minutes with a poison obtained from this root. The symptoms described by Barham are pain and swelling of the abdomen, vomiting and purging, dimness of sight, syncope, rapid diminution of the powers of life, and death in a few hours. Half a pint of the juice has produced death in an hour.

USES.—Dr. Wright says that the scrapings of the fresh root are successfully applied to ill-disposed ulcers; and Dr. Hamilton speaks of the instantaneous relief which he experienced on himself from the application of a cataplasm of the rasped roots, with all their juices unexpressed, to the spot where a nest of chigres (Pulex penetrans) had been dislodged. The root is used to catch birds, which, by eating it, lose the power of flying. It yields cassava meal and cassava starch.

1. FARINA MANDIOCE; Cassava or Cassada Meal; Farinha de Pau, or simply Farinha; Farine de Manioc.—This is obtained by washing and scraping the roots, then rasping or grating them, and subjecting the pulp to pressure, by which the poisonous juice is expressed. The residual compressed pulp is then dried over a fire, being stirred during the whole time. In this way is obtained cassava meal.

Cassava meal is a mixture of cassava starch, vegetable fibre, and proteine or albuminous matters. Dr. Shier found that in the sliced and dry roots the percentage of nitrogen is 0.78, but in the cassava meal (the juice expressed) only 0.36. If these numbers be multiplied by 6.5 (see foot-note at p. 106), the percentage quantity of protein or albuminous matters in the dried root will be 5.0, and in cassava meal 2.34.

I have received from Dr. Shier two kinds of cassava meal; one called cassava meal, the other termed cassava flour. I shall distinguish them as coarse and fine meal.

a. COARSE CASSAVA MEAL; Cassava Meal, Shier; Couaque or Couac, Guibourt. —This is meal which in coarseness is about equal to sawdust or small dried crumbs of bread. I have found a similar preparation in English commerce under the name of "Tapioca Flour from Bahia." Coarse cassava meal has a slight yellowish or brownish tint, varying in different samples.

b. FINE CASSAVA MEAL; Cassava Flour, Shier; Farine de Manioc, Guibourt. —This is a finer and whiter meal than the preceding. In fineness it resembles wheat flour.

Cassava bread or cassava cakes are made by baking the compressed cassava pulp on a hot plate, in the manner muffins and crumpets are baked in England.

Cassava meal and cassava bread are important and valuable articles of food to the inhabitants of tropical America. The flavour of cassava cakes reminds me of Scotch oatcakes.

2. AMYLUM MANDIOCE; Mandioca or Cassava Starch; Tapioca.—The juice which is expressed from the rasped root deposits on standing an amylos or starch (cassava starch), of which tapioca is made.

1 Quoted by Sloane, Jamaica, vol. ii. p. 303.
2 Journ. de Pharm. t. xvi. p. 310, l.90.
5 The details of the process for making cassava meal vary somewhat in different localities. According to Piso (De Medicina Brasil, lib. iv. p. 53), the roots are grated by a handmill somewhat similar to that used in the preparation of Tous-les-Mois (see ante, p. 228, Fig. 224). Edwards (Voyage up the River Amazon, p. 24, Lond. 1847) says they are grated upon stones, and the pulp compressed in a slender bag of rattan six feet in length.
6 Hortus Americanus, p. 31, 1794.
7 Mod. Plants of Jamaica.
8 Report, p. 15.
a. Cassava Starch; Tapioca Meal; Brazilian Arrow-root; Moussache or Gipipa.—The fecula or starch deposited from the expressed juice of the cassava root, after being washed and dried in the air without heat, constitutes the tapioca meal or Brazilian arrow-root of commerce. It is usually imported into this country from Rio Janeiro. For some years past it has been imported into France from Martinique, and is sold as arrow-root (Guiibourt). It is white and pulvulent, and resembles in external appearance genuine arrow-root (maranta starch). When examined by the microscope, however, it is readily distinguished.

Cassava starch, when examined by the microscope, is found to consist of small single grains, which, in the living plant, were united in groups or compound grains, each composed of 2, 3, or 4 grains. Most of the grains are mulllar-shaped, and, therefore, have been united in groups of two each: when seen endwise, they appear circular or globular. Some of them are truncated egg-shaped grains, with one or two facets at the truncation. The nucleus, central cavity, or hilum, is circular, surrounded with rings, and bursts in a stellate manner.

These statements apply equally to bitter cassava starch and sweet cassava starch sent to me from Demerara by Dr. Shier, as well as to starch obtained by myself from sweet cassava root received from Jamaica.

Cassava starch has not been analyzed; but there can be no doubt but that its composition is similar to that of other starches, and that its formula is C\textsubscript{6}H\textsubscript{10}O\textsubscript{6}. Its effects and uses are also like those of other starches (see ante, p. 119).

3. Tapioca.—This is imported from Bahia and Rio Janeiro. It is cassava meal, which while moist or damp has been heated, for the purpose of drying it, on hot plates. By this treatment the starch grains swell, many of them burst, and the whole agglomerate in small irregular masses or lumps. In consequence of the change thus effected in the starch grains, tapioca is partially soluble in cold water; and the filtered cold infusion strikes a blue colour with tincture of iodine. The drying to which it has been subjected renders it difficult of solution. In boiling water it swells up, and forms a transparent viseous jelly-like mass. Submitted to prolonged ebulition in a large quantity of water, it leaves an insoluble residue, which precipitates. This, when diluted with water and coloured by iodine, appears to consist of mucous flocks.

Made into puddings, tapioca is employed as a dietetical substance. Boiled in water or milk, and flavoured with sugar, spices, or wine, according to circumstances, it is used as an agreeable, nutritious, light, easily digestible article of food for the sick and convalescent. It is devoid of all irritating and stimulating properties.

136. Crozophora tinctoria, Necker.—Turnsole.

(\textit{Succus.})

\textit{Holiotropium tricoccum}, Pliny, lib. xxii. cap. 29; \textit{Croton tinctorium}, Linn.—South of France; Mediterranean coast. Cultivated since 1833 in the neighbourhood of Grand Gallarus, in the department of Gard, in France. The expressed juice is green; but, under the combined influence of the air and ammonium, it becomes purplish. Coarse sacking stained purple by this juice is termed turnsole rags (tournesol en draperaux), or beseta\textsuperscript{a} carules. These rags are exclusively employed by the Dutch; but for what purpose is not well known, though it has been supposed for colouring cheese, confectionery, liqueurs, &c.\textsuperscript{a}

\textsuperscript{a} The following are the measurements, in parts of an English inch, of ten grains of cassava starch. They were made by Mr. George Jackson:—

ORDER XXXIV. ARISTOLOCHIACEÆ, Lindley.—BIRTHWORTS.

ARISTOLOCHIÆ, Jussieu; ASARINÆ, Bartling.

Characters.—Flowers hermaphrodite, axillary, solitary. Calyx adherent (superior), tubular, monosepalous, with the segments valvate or induplicate in restivation, sometimes regular, sometimes very unequal. Stamens 6 to 12, epigynous, distinct, or adhering to the style and stigmas. Ovary inferior, 6-celled, very rarely 3—4-celled; ovules numerous, anatropous, horizontally attached to the axis. Style simple. Stigmas radiating, as numerous as the cells of the ovary. Fruit dry or succulent, 3—4—6-celled, many-seeded. Seeds thin, with a very minute embryo placed at the base of fleshy albumen—Herbs or shrubs, the latter often climbing. Wood without concentric zones and inseparable wedges. Leaves alternate, simple, stalked.

Properties.—Not important. The roots possess stimulant properties, owing to the presence of volatile oil. Some of them are acids. Bitter extractive renders them somewhat tonic.

137. ARISTOLOCHIA SERPENTARIA, Linn.—THE VIRGINIAN SNAKE-ROOT.

Aristolochia officinalis, Nees and Ebermayer.

Sex. Syst. Gynandra, Hexandria.

(Radix, L.—The root, E. D.)

History.—The first writer who distinctly mentions Virginian snake-root, or snake-weed, is Thomas Johnson, an apothecary of London, in his edition of Gerarde’s Herbal, published in 1633.

Botany. Gen. Char.—Calyx tubular, ventricose at the base, dilated at the apex, and extended into a ligula. Anthers 6, subsessile, inserted on the style. Stigma 6-lobed. Capsule 6-angled, 6-celled (Bot. Gall.).

Hab.—North America.

Collection and Properties.—The root (radix serpentariae) is collected in Western Pennsylvania and Virginia, in Ohio, Indiana, and Kentucky. It is imported in bales, usually containing about 100 lbs. As met with in the shops, it consists of a tuft of long, slender, yellowish or brownish fibres, attached to a long, contorted head or caudex. The odour is aromatic, the taste warm and bitter.

Composition.—It was analyzed by Bucholz in 1807; by Chevallier in 1820; and by Pechier in 1829.

1. Volatile Oil.—Grassmann obtained only half an ounce from 100 lbs. of the root. Its colour is yellowish, its odour considerable, its taste not very strong. Grassmann compares the odour and taste to those of valerian and camphor combined.

2. Bitter Principle; Extractive, Bucholz and Chevallier.—This is very bitter and slightly acid. It is soluble in both water and spirit. Its solution, which is yellow, is rendered brown by alkalies, but is unchanged by the ferruginous salts.

1 United States Dispensatory.
2 Journ. de Pharm. vi. 365.
3 Quoted by Dr. W. C. Martius, Pharmacogn.
5 Gmelin, op. cit.
6 Lewis, Med. Med.
Physiological Effects.—These have been examined by Jörg and his pupils.1

In small doses, serpentine promotes the appetite. In large doses, it causes nausea, flatulence, uneasy sensation at the stomach, and more frequent but not liquid stools. After its absorption, it increases the frequency and fulness of the pulse, augments the heat of the skin, and promotes secretion and exhalation. Furthermore, it would appear, from the experiments before referred to, that it causes disturbance of the cerebral functions, and produces headache, sense of oppression within the skull, and disturbed sleep.

In these properties, serpentine bears some analogy to, but is much weaker than, camphor. It is more powerful than contrayerva.

Uses.—Its employment is indicated in cases of torpor and atony. It was formerly termed alexipharmic, on account of its fancied power of curing the bite of a rattlesnake and of a mad dog.2 At the present time it is rarely employed. It has been much esteemed as a stimulant in fevers, both continued and intermittent. A scruple of serpentine, taken in three ounces of wine, is mentioned by Sydenham3 as a cheap remedy for tertians in poor people. Dr. Cullen4 considered it as suited for the low and advanced stage of typhus only. In an epidemiological affection of the throat (called the throat-distemper), it was given internally as a diaphoretic, and used with sumach berries, in the form of a decoction, as a gargle, with benefit.5

Administration.—The dose of it in substance is from ten to thirty grains. The infusion is the best form for the administration of serpentine.

1. INFUSUM SERPENTARII, L. E. [U. S.]; Infusion of Serpentine, or Snake-root. — (Serpentary 328; Boiling Water Oj.) Infuse for four hours in a covered vessel, and strain [through linen or calico, E.].—Dose, f3j or f3ij every two or three hours, according to circumstances.

2. TINCTURA SERPENTARII, L. E. [U. S.]; Tincture of Serpentine, or Snake-root. — (Serpentary, bruised [in moderately fine powder, E.], 5iij, L.; Proof Spirit Oij; and Cochineal, bruised, 5j, E. Macerate for seven days, and filter. “Proceed by percolation or digestion as for the tincture of cinchona,” E.—[Take of Virginia Snake-root, bruised, 5iij; Diluted Alcohol Oij. Macerate for fourteen days, express, and filter through paper, U. S.]—Used as an adjunct to tonic infusions. Dose, from f3j to f3ij.

138. ASARUM EUROPÆUM, Linn.—COMMON ASARABACCA.

Gen. Syst. Dodecandria, Monogynia.

(Folia, L. D.)

History.—This plant was used in medicine by the ancients. Dioscorides6 calls it ágavos.

Sp. Char.—Leaves 2 on each stem, kidney-shaped, obtuse [somewhat hairy] (Smith).7

The branching root-fibres arise from an underground stem or rhizome. The aerial stems are several from each rhizome. Leaves petiolated. From the axil of the two leaves springs a solitary, rather large, drooping flower, upon a short peduncle, of a greenish-brown colour and coriaceous substance. Segment of the calyx incurved. Capsule coriaceous. Seeds ovoid, with horny albumen.

Hab.—Indigenous. Perennial. Flowers in May.

Description.—The whole plant (root-fibres, rhizome, and aerial stems, with

2 Dale, Pharmacologia.
3 Wals, translated by Dr. Pechez, 4th ed. p. 223.
4 Met. Med.
5 Lib. i. cap. ix.

VOL. II.—25
leaves and flowers) is kept in the shops under the name of asarabacca (radix cum herbâ asari), but the leaves only are directed to be used in the Pharmacopoeia. Dr. Batty\(^1\) states that the plant is gathered for medicinal uses in the woods near Kirkby Lonsdale, Westmoreland. The rhizome is about as thick as a goose-quill, grayish, quadrangular, knotted. It has a pepper-like odour, and an 'acrid' taste. The leaves are almost inodorous, but have an acid, aromatic, and bitter taste.

**Composition.**—Goerz\(^2\) published an analysis of the root in 1784; Lassaigne and Feneulle another in 1820;\(^3\) Regimbeau a third in 1827;\(^4\) and Gräger a fourth in 1830.\(^5\)

1. **Volatile Oily Matters.**—By submitting asarabacca root to distillation with water, three volatile oily matters are obtained; one liquid and two solid, at ordinary temperatures.

a. **Liquid Volatile Oil (Oleum Asari).**—It is yellow, glutinous, lighter than water, and has an acid, burning taste, and a penetrating valerian-like odour. It is slightly soluble in water, more so in alcohol, ether, and the oils (volatile and fixed). Its constituents are \(\text{C}_7\text{H}_{10}\text{O}\).

b. **Asarite** of Gräger.—In small needles of a silky lustre. It is odourless and tasteless. It is fusible and volatileizable by heat; its vapour being white and very irritating. It is soluble in alcohol, ether, and the volatile oils, but not in water. Both nitric and sulphuric acids dissolve the crystals without the evolution of gas: if water be added to the sulphuric solution, the asarite is thrown down unchanged.

c. **Asarum-camphor.**—Is distinguished from asarite by the following characters: Water throws it down from its alcoholic solution in cubes or six-sided prisms, whereas asarite is precipitated in delicate flexible needles. It dissolves in nitric acid without effervescence. Water added to its sulphuric solution throws down a brown resin. After fusion, it has the form of a crystalline, striated mass. Its composition is \(\text{C}_7\text{H}_{10}\text{O}\). Blanchet and Sell regard it as the hydrate of the liquid volatile oil.

2. **Bitter Principle of Asarabacca (Asarin of Gräger and of some other pharmacologists).**—Brownish, very bitter, soluble in alcohol.

**Physiological Effects.**—Every part of the plant possesses acid properties. Applied to the mucous membrane of the nose, it excites sneezing, increased secretion of mucus, and even a discharge of blood. Swallowed, it causes vomiting, purging, and griping pains. It is also said to possess diuretic and diaphoretic properties. Dr. Cullen has enumerated it in his list of diuretics, but expresses his doubts whether it possesses any specific power of stimulating the renal vessels.

**Uses.**—Asarabacca has been employed in medicine to excite vomiting, and as an er rhine. As an emetic, it is now superseded by ipecacuanha and tartarized antimony. As an er rhine, to excite irritation and a discharge of mucus from the nasal membrane, it has been used in certain affections of the brain, eyes, face, mouth, and throat, on the principle of counter-irritation: thus in paralytic affections of the mouth and tongue, in toothache, and in ophthalmia.

**Administration.**—We may administer either the root or leaves, Recollecting that the latter are somewhat milder than the former. As an emetic, the dose is half a drachm to a drachm. As an er rhine, one or two grains of the root, or three

---

or four grains of the dried leaves, are sniffed up the nostrils every night.—The powder of this plant is supposed to form the basis of cephalic sniff.

PULVIR ASARI COMPOSITES; Compound Powder of Asarabacca.—(Asarabacca Leaves, dried, s; Lavender Flowers, dried, s). Reduce them together to powder.—Used as an effusive in headache and ophthalmia. Dose, from grs. v to grs. vii.

Sex. Syst. Gynandra, Hexandra.

(Radix.)

Both of these plants are natives of the South of Europe. Their roots are still kept in the shops. The long aristolochia root is several inches in length, one or two inches broad, and has a more or less cylindrical form. The round aristolochia root has a more rounded and knobby form. Both kinds are bitter and acrid, and have, especially when powdered, a disagreeable odour. They contain extractive matter and starch. Lessing found ulmin in the long species. Their effects are stimulating and tonic. Their stimulant effects are supposed by some to be principally directed to the abdominal and pelvic viscera. They have been employed in aromatia as an emmenagogue. Their dose is from s to s. Round aristolochia root is a constituent of the Duke of Portland's powder for the gout, which consisted of equal quantities of the roots of Gentian and Birthwort (Aristolochia rotunda), the tops and leaves of Germander (Chamadrys), Ground Pine (Chamaepitys), and lesser Centaury (Chimonia Centaurium), powdered and mixed together.¹

ORDER XXXV. LAURACEÆ, Lindley.—LAURELS.

LAURI, Jussieu.—LAURANÆ, Vent. and Rob. Brown.

Characters.—Calyx 4- to 6-cleft, with imbricated activation, the limb sometimes obsolete. Petals 0. Stamenm definite, perigynous opposite the segments of the calyx, and usually twice as numerous; the 3 innermost, which are opposite the 3 inner segments of the calyx, sterile or deficient; the 6 outermost scarcely ever abortive; anthers adnate, 2- to 4-celled; the cells bursting by a longitudinal persistent valve from the base to the apex; the outer anthers valved inwards, the inner valved outwards [or both valved inwards, Lindl.]. Gland usually present at the base of the inner filaments. Ovary single, superior, 1-celled [formed of 3 valuate carpel-lary leaves, and as many rib-like placenta stationed at the sutures, all generally imperfect except one, Endl.], with 1 or 2 single pendulous ovules; style simple; stigma oblong, 2- or 3-lobed. Fruit bacate or drupaceous, naked or covered. Seed without albumen; embryo inverted; cotyle-dons large, plano-convex, petlate near the base! radicle very short, included, superior; plumule conspicuous, 2-leaved.—Trees, often of great size. Leaves without stipules, alternate, seldom opposite, entire, or very nearly lobed. Inflorescence panicked or umbellet (Rob. Brown).

Properties.—The plants of this order owe their most important qualities to the presence of volatile oil, which is found, more or less abundantly, in all parts of the vegetable. This oil is sometimes liquid and highly aromatic, as oil of cinnamon; at others, it is solid in ordinary temperatures, and is endowed with narcotic properties, as camphor. The acrid principle of some species is probably a volatile oil.

In the bark and leaves, the volatile oil is usually associated with tannic acid, which gives them astringency, as in cinnamon. In the fruit and seeds, on the other hand, it is usually combined or mixed with fixed oil, as in bay-berries.

Besides the officinal lauraceous barks, presently to be described, there are several others which have obtained considerable celebrity, in the countries producing them, on account of their aromatic qualities.

Two of these bear the name of clove bark, on account of their colour. The Indian clove bark or coriæ ciliataæ is a large flat bark, and is obtained from Cinnamonum Ciliatae, Blume, a native of the Indian islands. Its properties are analogous to those of Cinnamon, and is rarely met with in London. I have received from Dr. Martyn, of Hesse Darmstadt, a bark marked Ciliatae papuanæ. It is, I presume, the produce of Cinnamonum xanthicron of Blume.

¹ See Dr. Clephane's Inquiry into the Origin of the Gout Powder, in the Med. Observ. and Ing. vol. i. Lond. Dr. Clephane concludes that "Callosus Aurelianuæ disoontiamæ and Aéthius's antidotæ ex douobus centauriæ generibus were the same medicine, and are the old names for the Duke of Portland's Powder."

² See Pereira, in Lindley's Flora Medica, p. 331.
The Brazilian clove bark, or clove cassia bark, cortex cassia caryophyllata, is the produce of Dyepellium caryophyllatum, and grows in Para and Rio Negro. Its bark occurs in tubular quills.

Massouy bark (in commerce Missi) is the cortex onimus of Rampbhius. It is used in the cosmetics of the natives of India. I have never found it in the London shops.

Sintec bark is the produce of Cinnamomum Sintec, Blume. Its properties are analogous to those of Cailawain.

The foia malabathrik of India are obtained from Cinnamomum nitiitum, Hooker and Blume; and from C. Tamala. They are aromatic tonics, but are not found in the London market.

140. CINNAMOMUM ZEYLANICUM, Nees.—THE CEYLON CINNAMON.

Laurus Cinnamomum, Linn.

Sex. Syst. Eneandria, Monoogyne.

(Cortex; et Oleum e cortice destillatum, L.—Bark; and volatile oil of the bark, E.—The bark, D.)

History.—Cinnamon (Kinnam, Hebr.) is mentioned in the Old Testament, about 1490 years before Christ. In all probability the Hebrews received it from the Arabsians, who must, therefore, have had commercial dealings with India at this early period. The first notice of cinnamon (zizinamorp) by the Greek writers occurs in Herodotus, who died 413 years before Christ. Probably both the Hebrew and Greek names for this bark are derived from the Cingalese cacy-nama (dulce lignum), or the Malayan kaimanis. Hippocrates employed cinnamon externally. Dioscorides describes several kinds of cinnamon.

Botany. Gen. Char.—Flowers hermaphrodite or polygamous. Calyx 6-cleft, with the limb deciduous. Stamina 12, in 4 rows; the 9 external ones fertile, the 3 inner ones capitate, abortive; the 3 most internal of the fertile stamina having 2 sessile glands at the base: anthers 4-celled, the 3 inner turned outwards. Ovary 1-celled, with 1 ovule. Fruit (a berry) seated on a cup-like calyx. Leaves ribbed. Leaf-buds naked. Flowers panied, rarely fascicled. (Condensed from Endlicher.)

Sp. Char.—Branches somewhat 4-cornered, smooth. Leaves ovate or ovate-oblong, tapering into an obtuse point, triple-nerved, or 3-nerved, reticulated on the under side, smooth, the uppermost the smallest. Panicles terminal and axillary, stalked. Flowers hoary and silky; segments oblong, deciduous in the middle (Nees).

Botanists admit several varieties of this species; the most important are—

a. Broad-leaved, Moon; Mu-pat (Cingalese).—The plant above described.

b. Narrow-leaved, Moon; Cinnamomum zeylanicum, var. ? Cassia, Nees; Heen-pat (Cingalese).—This variety, which I have received from Ceylon under the name of Bastard Cinnamon, has oblong or elliptical leaves, much tapering to the point, and acute at the base.

Percival mentions four varieties which are barked: 1st, Rasse curudu, or honey cinnamon, with broad leaves, yields the best bark; 2dly, Nai curudu, or snake cinnamon, also with large leaves, not greatly inferior to the former; 3dly, Capuru curudu, or camphor cinnamon, an inferior kind; 4thly, cabaitu curudu, or astringent cinnamon, with smaller leaves; its bark has a harsh taste.

Hab.—Cultivated in Ceylon and Java.

Production.—The cinnamon bark of Ceylon is obtained by the cultivation of the plant. The principal cinnamon gardens lie in the neighbourhood of Columbo.
The bark-peelers, or cholias, having selected a tree of the best quality, lop off such branches as are three years old, and which appear proper for the purpose. Shoots or branches, much less than half an inch, or more than two or three inches in diameter, are not peeled. The peeling is effected by making two opposite, or, when the branch is thick, three or four, longitudinal incisions, and then elevating the bark by introducing the peeling-knife beneath it. When the bark adheres firmly, its separation is promoted by friction with the handle of the knife. In twenty-four hours, the epidermis and greenish pulpy matter (rete mucosum) are carefully scraped off. In a few hours, the smaller quills are introduced into the larger ones, and in this way a congeries of quills formed, often measuring forty inches long. The bark is then dried in the sun, and afterwards made into bundles with pieces of split bamboo twigs.

Cinnamon walking-sticks.—The hazel-like walking-sticks, so much esteemed by visitors to Ceylon, are obtained from the shoots which spring almost perpendicularly from the roots after the parent bush or tree has been cut down.

Commerce.—Cinnamon is imported in bales, boxes, and chests, from Ceylon principally; but in part also from Madras, Tellicherry, and rarely from Java and other places.

In order to preserve and improve the quality of the bark, black pepper is sprinkled among the bales of cinnamon in stowing them at Ceylon (Percival). Mr. Bennett states that ships are sometimes detained for several weeks, through the want of pepper to fill the interstices between the bales in the holds.

When cinnamon arrives in London, it is unpacked and examined; all the mouldy and broken pieces are removed from it. It is then re-made into bales. These are cylindrical, 3 feet 6 inches long, but of variable diameter, perhaps 16 inches on the average. These bales are enveloped by a coarse cloth, called gunny. The cinnamon in boxes and chests is usually the small, inferior, and mouldy pieces.

Description.—Four kinds of cinnamon are distinguished in the London market; namely, Ceylon, Tellicherry, Malabar, and Java cinnamon. The latter, however, is rarely met with. A fifth kind, called Cayenne, occurs in French commerce.

The Chinese cinnamon of continental writers is Cassia lignea of English commerce.

1. Ceylon Cinnamon (Cinnamomum zeylanicum seu Cinnamomum acutum).—This is the most esteemed kind. The fasciculi or compound quills, of which the bales are made up, are about 3 feet 6 inches long, slender, and shivery, and are composed of several smaller quills inclosed one within the other. The bark is thin (the finest being scarcely thicker than drawing paper), smooth, of a light yellow-brown or brownish-yellow, moderately pliable, with a splintery fracture, especially in the longitudinal direction. The inner side or liber is darker and browner, and contains, according to Nees, small medullary rays filled with a red juice, and which he regards as the peculiar bearers of the aroma. The colour of the bark is highly fragrant. The flavour is warm, sweetish, and agreeable. Inspection and tasting are the methods resorted to for ascertaining the qualities of cinnamon.

Ceylon cinnamon is characterized by being cut obliquely at the bottom of the quill, whereas the other kinds are cut transversely. In the London market three qualities of Ceylon cinnamon are distinguished; viz. first, seconds, and thirds. Inferior kinds are thicker, darker, browner, and have a pungent, succeeded by a bitter taste.

Thin, very much convoluted, smaller quills being inclosed in larger ones. Ph. Lond.

2. Tellicherry or Bombay Cinnamon is grown on one estate only, at Tellicherry,
by Mr. Brown, and is wholly consigned to Messrs. Forbes and Co. Only 120 or 180 bales are annually imported. In appearance it is equal to the Ceylon kinds; but the internal surface of the bark is more fibrous, and the flavour is inferior. It is superior to the Malabar variety.

3. Madras or Malabar Cinnamon is of inferior quality. It is grown, I am informed, on the Coromandel coast. It is coarser and inferior in flavour to the other kinds. In thickness it approximates to Cassia lignea. Its quality has annually deteriorated since its introduction into the market. It does not meet with a ready sale, and it is expected that its importation will cease.

4. Java Cinnamon.—This is said to be equal in quality to the Ceylon sort.  

5. Cayenne Cinnamon.—This is unknown in the London market. Its volatile oil is more acrid and peppery than the oil from Ceylon cinnamon.

SUBSTITUTION.—In commerce, Cassia lignea (called on the continent Chinese cinnamon) is frequently substituted for cinnamon. It is distinguished by its greater thickness, its short resinous fracture, its less delicacy but greater strength of flavour, its shorter quills, and its being packed in small bundles. Moreover, it may be distinguished chemically by the action of iodine on its infusion (see infra). The difference of flavour is best distinguished when the barks are ground to powder. The great consumers of cinnamon are the chocolate-makers of Spain, Italy, France, and Mexico, and by them the difference of flavour between cinnamon and cassia is readily detected. An extensive dealer in cinnamon informs me that the Germans, Turks, and Russians prefer cassia, and will not purchase cinnamon, the delicate flavour of which is not strong enough for them. In illustration of this, I was told that some cinnamon (valued at 8s. 6d. per lb.) having been by mistake sent to Constantinople, was unsaleable there at any price; while cassia lignea (worth about 6d. per lb.) was in great request.

COMPOSITION.—In 1817, Vauquelin*a made a comparative analysis of the cinnamon of Ceylon and Cayenne. The constituents of both were found to be volatile oil, tannin, mucilage, colouring matter (partially soluble in water and in alcohol, but insoluble in ether), resin, an acid, and ligneous fibre. Starch is a constituent of cinnamon, though not mentioned in this analysis.

CHEMICAL CHARACTERISTICS.—Sesquichloride of iron causes a greenish flocculent precipitate (tannate of iron) in infusion of cinnamon. Solution of gelatine also occasions a precipitate (tannate of gelatine) in the infusion.

A decoction of cinnamon may be distinguished from a decoction of cassia lignea by tincture of iodine; which gives a blue colour (iodine of starch) with the latter, but not with the former. Both barks contain starch, but cinnamon appears to contain a larger proportion of some principle (tannic acid?) which destroys the blue colour of iodide of starch; for, if the decoction of cassia lignea rendered blue by iodine be added to the decoction of cinnamon, the blue colour disappears.

PHYSIOLOGICAL EFFECTS.—Cinnamon produces the effects of the spices already described (see ante, p. 221). In moderate doses, it stimulates the stomach, produces a sensation of warmth in the epigastric region, and promotes the assimilative functions. The repeated use of it disposes to costiveness.

In full doses, it acts as a general stimulant to the vascular and nervous systems. Some writers regard it as acting specifically on the uterus.a

USES.—The uses of cinnamon are those of the species generally, and which have been before noticed. It is employed by the cook as an agreeable condiment. In medicine, it is frequently added to other substances: as to the bitter infusions, to improve their flavour; and to purgatives, to check their griping qualities. As a cordial, stimulant, and tonic, it is indicated in all cases characterized by feebleness and atony. As an astringent, it is employed in diarrhoea, usually in combination with chalk, the vegetable infusions, or opium. As a cordial

1 Proceedings of the Committee of Commerce and Agriculture of the Asiatic Society, p. 147.
2 Vauquelin, Journ. de Pharm. t. iii. p. 431.
3 Journ. de Pharmacie. t. iii. p. 433.
and stimulant, it is exhibited in the latter stages of low fever. In flatulent and spasmodic affections of the alimentary canal, it often proves a very efficient carminative and antispasmodic. It checks nausea and vomiting. It has also been used in uterine hemorrhage.

ADMINISTRATION.—The dose of it in substance is from ten grains to half a drachm.

1. OLEUM CINNAMOMI, L. E. D. [U. S.]; Oleum Cinnamomi veri, offic.; Oil of Cinnamon.—(Obtained in Ceylon by macerating the inferior pieces of the bark, reduced to a gross powder, in sea-water for two days, when both are submitted to distillation.)—As imported, the oil varies somewhat in its colour from yellow to cherry-red; the paler varieties are most esteemed; hence London druggists frequently submit the red oil of cinnamon to distillation, by which they procure two pale yellow oils; one lighter (amounting to about the quarter of the whole), the other heavier than water. The loss on this process is considerable, being near 10 per cent. Percival says that the oil obtained from the finer sorts of cinnamon is of a beautiful gold colour, while that from the coarser bark is darker and brownish.

Its odour is pleasant, and purely cinnamomic. Its taste is at first sweetish, afterwards cinnammonic, burning, and acid.

Cinnamon oil of commerce is a complex substance, consisting of a mixture or compound of two or more bodies. The principal constituent, and which is considered to be cinnamon oil properly so called, is the hydruret of cinnamyle, whose formula, according to Mulder, is \( C_{9}H_{10}O_{5} \); but, according to Dumas and Peligot, \( C_{10}H_{15}O_{4} \). Mulder supposed that the differences in these formulæ depend on the oil analyzed by Dumas and Peligot not having been quite fresh.

By exposure to the air, oil of cinnamon absorbs oxygen, and produces cinnamic acid, two resins, and water.

\[ 2(C_{9}H_{10}O_{5}) + 8O \rightarrow C_{10}H_{15}O_{4} + C_{10}H_{15}O_{4} + 6HO \]

With nitric acid, oil of cinnamon combines to form a white crystalline nitrate \( (C_{9}H_{10}O_{5})NO_{3} \) and a red oil. With ammonia, the oil unites to form a crystalline solid amide, called cinnhydramide, whose formula is \( C_{10}H_{14}N_{4} \).

On account of their great difference in commercial value, and resemblance in physical and chemical properties, oil of cassia is sometimes substituted for, or admixed with, genuine oil of cinnamon. The finer and more delicate odour of the latter is the chief distinction between them.

The Edinburgh College gives the following characters of oil of cinnamon:

"Cherry-red when old; wine yellow when recent; odour purely cinnamomic: nitric acid converts it nearly into a uniform crystalline mass."

These characters, however, are not peculiar to this oil, as they are also possessed by oil of cassia.

Zetter\(^{6}\) says that oil of cinnamon is a thinner and specifically lighter oil, which does not become turbid at a lower temperature than the oil of cassia. Most, if not all, the other characteristic differences which he has given probably relate rather to particular samples of the oils than to their peculiar natures.

Oil of cinnamon root.—In 1848 some of this oil was imported. Its colour was pale yellow, and its odour that of cinnamon; but not so delicate as the oil of the bark.

Oil of cinnamon is sometimes employed as a powerful stimulant in paralysis of the tongue, in syncope, or in cramp of the stomach. But its principal use is as an adjuvant to other medicines. The dose of it is from one to three minims.

2. OLEUM CINNAMOMI FOLIAREM; Oil of Cinnamon Leaf.—It is exported from Ceylon, and is sometimes called, on account of its odour, clove oil.

---

I am informed by a gentleman on whose estate in Ceylon it is obtained, that it is procured by macerating the leaves in sea-water, and afterwards submitting both to distillation. It is a yellow liquid, heavier than water, and has an odour and taste analogous to those of oil of cloves.

Bennett declares it to be equal in aromatic pungency to the oil made from the clove at the Molucca Islands. Oil of cinnamon leaf is, however, specifically lighter than genuine oil of cloves; but, like the latter, yields a dark blue colour with the tincture of the sesquichloride of iron. Its effects and uses are similar to those of oil of cloves.

3. AQUA CINNAMOMI, L. E. D. [U. S.]; Cinnamon Water.—(Cinnamon, bruised, lbss; Water Cong. i.) Let a gallon distil. Or, Oil of Cinnamon fij; Powdered Flint 3ij; Distilled Water Cong. j. Diligently rub the oil, first with the flint, afterwards with the water, and strain the liquor, L.—Cinnamon Bark, bruised, 3xvijj; Water two gallons; Rectified Spirit fijij. Mix them together, and distil off one gallon, E.—Essence of Cinnamon fij; Distilled Water half a gallon. Mix with agitation, and filter through paper, D.—(Take Oil of Cinnamon fijss; Carbonate of Magnesia 3ij; Distilled Water Oij. Rub the oil of cinnamon, first with the carbonate of magnesia, then with the water gradually added, and filter through paper, U. S.)—Cinnamon water is principally employed as a vehicle for other medicines. It is aromatic and carminative. Groppert says it is poisonous to plants. By dissolving iodine and iodide of potassium in cinnamon water, a crystalline compound is produced, consisting of iodide of potassium 12.55, iodine 28.14, oil of cinnamon 59.81.²

4. SPIRITUS CINNAMOMI, L. E.; Spirit of Cinnamon.—(Oil of Cinnamon 3ij; Proof Spirit Cong. j; Water Oij. Dissolve, L.—Cinnamon, in coarse powder, lbj; Proof Spirit Ovij. Macerate for two days in a covered vessel; add a pint and a half of water; and distil off seven pints, E.)—Stimulant. Dose, fij to fijiv.

5. ESSENTIA CINNAMOMI, D.; Essence of Cinnamon.—(Oil of Cinnamon fij; Rectified Spirit fijix. Mix with agitation, D.)—Used for making cinnamon water. A few drops may be taken on a lump of sugar as a stimulant.

6. TINCTURA CINNAMOMI, L. E. [U. S.]; Tincture of Cinnamon.—(Cinnamon, bruised, 3ijss [in moderately fine powder, E.]; Proof Spirit Oij [U. S.]. Macerate for seven days, and strain. [Proceed by percolation or digestion, as directed for tincture of cassia, E.])—Commonly used as an adjuvant to cretaceous, astringent, tonic, or purgative mixtures. It has also been employed in uterine hemorrhage.² Dose, fij to fijiv.

7. TINCTURA CINNAMOMI COMPOSITA, L. E. D. [U. S.]; Compound Tincture of Cinnamon.—(Cinnamon, bruised [in fine powder, if percolation be followed, E.], 3j [3ij, D.]; Cardamon, bruised, 3ss [3j, E. D.]; Long Pepper, powdered [ground finely, E.], 3jss [3ijj, E. [not used by the Dublin College]; Ginger 3jss [not used by the Ed. College [3ss, D.]]; Proof Spirit Oij. Macerate for seven fourteen, D. [U. S.] days, express and strain, L. "This tincture is best prepared by the method of percolation as directed for the compound tincture of cardamom. But it may also be made in the ordinary way by digestion for seven days, straining and expressing the liquor, and then filtering it," E. [The formula of the U. S. is like that of the London Pharm.]—Cordial and aromatic. Used in the same cases as the last. Dose, fij to fijij.

8. PULVIS CINNAMOMI COMPOSITUS, L.; Pulvis Aromaticus, E. D. [U. S.]; Compound Powder of Cinnamon; Aromatic Powder.—(Cinnamon 3ij; Cardamom 3ss [3j, D. (U. S.)]; Ginger 3j [3ij, D.]; Long Pepper 3ss, L.; Nutmeg 3j, D. (U. S.).] Rub them together, so that a very fine powder may be made, L. D.—

CINNAMOMUM CASSIA, Blume.—THE CINNAMON CASSIA.

Cinnamomum aromaticum, Nees.

Sex. Syst. Enneandra, Monogyne.

(Cassia-bark. Oil of Cassia, E.—Cassia lignea, and Cassia buds, offic.)

HISTORY.—It is highly probable that the bark, now called cassia lignea, was known to the ancient Greeks and Romans; but we cannot positively prove this. The barks termed by the ancients cinnamomum (κιννάμωμος) and cassia (κασσία), as well as the trees yielding these substances, are too imperfectly described to enable us to determine with precision the substances referred to. The cassia tree is called in Chinese Kwei ( Qui). Cassia lignea is called Kwei Pe, or Cassia skin; while Cassia buds are termed Kwei Tse, or Cassia seeds. Cinnamon is called Fuh Kwei (vulgarily Yoke Qui), or Precious Cassia. It is not a product of China.

BOTANY. Gen. Char.—Vide Cinnamomum zeylanicum.

Sp. Char.—Leaves opposite, sometimes alternate, oblong-lanceolate, triple-nerved; the nerves vanishing at the point of the leaf. Petioles and younger branches silky-tomentose. Stem arborescent (Blume). *

Hab.—China; cultivated in Java.

The tree known in Ceylon as the Dawul Kurunda was erroneously supposed by Linnaeus to be the source of cassia bark, and hence he termed it Laurus Cassia. The Dublin College has been led into the same error. Many years since, Mr. Marshall stated that the bark of Dawul Kurunda was not aromatic like cinnamon, but had the bitter taste and the odour of myrrh.

1 Psalm xlv. 9.
2 Ann. of Phil. vol. x. 1217.
This tree is the *Litsea Ceylanica* of recent botanists. Mr. Marshall declares that in Ceylon it is never decorticated, and that the coarse cinnamon (i.e. cinnamon procured from thick shoots or large branches of *Cinnamomum zeylanicum*) has been imported into England, and sold under the denomination of cassia. It has been erroneously inferred from this statement that the cassia lignea of European commerce was merely coarse cinnamon; but if this were the case, it would be somewhat remarkable that cassia lignea is not imported from Ceylon. It is not at all improbable that coarse Ceylon cinnamon may have been sold in the London market as cassia lignea; but this by no means establishes the identity of the two barks. Such an occurrence can now scarcely happen, seeing that all cinnamon (coarse as well as fine) exported from Ceylon pays a duty of 3s. per lb, while the value of cassia lignea in bond is about 6d. per lb.

In the *Pan tsaoou* (a Chinese herbal) is a drawing of the Cassia tree. It is represented growing on a hill, and as having a very crooked and knotted stem.

**Description.**—Two substances are believed to be obtained from this species; namely, the bark called cassia lignea, and the flower buds termed cassia buds.

1. **Cassia lignea** (*cortex cassiae*) is regarded on the continent of Europe, and in America, as a sort of cinnamon. In English commerce, it is always distinguished. It is imported in chests. It resembles cinnamon in many of its qualities. It is made up in bundles, which are tied with slips of bamboo. It has the same general appearance, smell, and taste as cinnamon; but its substance is thicker, its appearance coarser, its colour darker, browner, and duller; its flavour, though cinnamon-like, is much less sweet and fine than that of Ceylon cinnamon, but is more pungent, and is followed by a bitter taste; it is less closely quilled, and breaks shorter, than genuine cinnamon (see ante, p. 390). It is imported from Singapore, Calcutta, Bombay, and Manila.

1. **China cassia lignea** (sometimes called *China cinnamon*) is the best kind. It is usually imported from Singapore, rarely from Canton direct. Mr. Reeves says vast quantities of both cassia buds and cassia lignea are annually brought to Canton from the province of Kwangse, whose principal city (*Kwei Lin Too*), literally the city of the Forest (or Grove) of Cassia trees, derives its name from the forests of cassia around it.

The Chinese themselves use a much thicker bark (which they call *Gan Kwei Pe*), unfit for the European market. Mr. Reeves informs me that they esteem it so highly as to pay nearly 10 dollars per lb. for it. A very fine quality is occasionally met with, and commands the enormous price of 100 dollars per catty (1¾ lb.) A specimen of it, with which he has kindly furnished me, is straight, semi-cylindrical, 11 inches long, rather more than an inch wide, and about one-sixth or one-eighth of an inch thick. Externally it is warted, and covered with crustaceous lichens. Internally, it is deep brown. Its odour and flavour are those of cassia. Mr. Reeves also informs me that the best cassia lignea is cut in the 3d or 4th moon, the second sort in the 6th or 7th moon.

2. **Malabar cassia lignea.**—This is brought from Bombay. It is thicker and coarser than that of China, and is more subject to foul packing; hence each bundle requires separate inspection. It may, perhaps, be coarse cinnamon; for Dr. White states that the bark of the older branches of the genuine cinnamon plant is exported from the Malabar coast as cassia.

3. **Manilla cassia lignea.**—This, I am informed, is usually sold in bond for continental consumption. I have received a specimen of bark ticketed "Cassia vera from Manilla," the epidermis of which was imperfectly removed.

4. **Mauritius cassia lignea.**—This is occasionally met with.

2. **Cassia buds** (*flores cassiae immatures; clavelli cinnamon*) are not contained in any of the British Pharmacopoeias. They are the produce of China, and are probably procured from the same plant which yields cassia lignea. Mr. Reeves

---

2 *Annals of Philosophy*, vol. x. 1817.
3 In the *American pharmacopoeia*, both cinnamon and cassia lignea are included under the name of cinnamon.
5 *Milburn's Orient. Comm.*
CINNAMON CASSIA:—Composition; Effects; Administration. 395
tells me that he has always understood and has no doubt that both cassia buds and cassia lignea are obtained from the same trees. The buds are gathered, he informs me, in the 8th or 9th moon. Dr. T. W. C. Martius1 says "that, according to the latest observations which the elder Nees has made known, cassia buds are the calyces (Fruchtkelche) of Cinnamomum aromaticum, about one-fourth of their normal size. It is also said that they are collected from Cinnamomum dulce (Nees), which is found in China." Cassia buds bear some resemblance to cloves, but are smaller, or to nails with round heads; they have the odour and flavour of cassia lignea or cinnamon. The exports from Canton in 1831 were 177,866 lbs., and the imports into Great Britain in 1832 were 75,173 lbs.2 In 1840, 6,406 lbs. paid duty. Cassia buds have not yet been analyzed; their constituents are similar to those of cassia lignea; they yield a volatile oil by distillation, and contain tannic acid.

COMPOSITION.—Cassia lignea was analyzed by Bucholz,3 who obtained the following results: Volatile oil, 0.8; resin, 4.0; gummy (astringent) extractive, 14.0; woody fibre with bassorin, 64.3; water and loss, 16.3 = 100.0.

CHEMICAL CHARACTERISTICS.—Sesquichloride of iron renders decoction of cassia lignea dark green, and causes a precipitate (tannate of iron). Gelatine also produces a precipitate (tannate of gelatine). If tincture of iodine be added to it, a blue colour (iodide of starch) is produced. By this cassia lignea may be distinguished from genuine cinnamon (see ante, p. 389).

PHYSIOLOGICAL EFFECTS.—Similar to those of cinnamon. Sundelin* regards it as being more astringent.

USES.—Are the same as those of cinnamon.

ADMINISTRATION.—Dose, grs. x to 3ss.

1. OLEUM CASSIE, E.; Oil of Cassia; Oil of Chinese Cinnamon.—(Obtained from cassia lignea by distillation with water.)—Its properties and composition are similar to those of oil of cinnamon, before described (see ante, p. 391). Its odour and flavour, however, are inferior to those of the latter. Its colour is usually pale yellow. Nitric acid converts it into a crystalline mass. Its effects and uses are similar to those of oil of cinnamon. It is employed in the preparation of Aqua and Spiritus Cassiae.—Dose, gtt. j to gtt. iv.

2. AQUA CASSIE, E.; Cassia Water.—(Cassia bark, bruised, 3xvij; Water Cong. ii; Rectified Spirit f3ij. Mix them together, and distil off one gallon.)—Used as an aromatic vehicle for other medicines. It is usually prepared from the oil in the same way that cinnamon water is commonly made.

3. SPIRITUS CASSIE, E.; Spirit of Cassia.—(Cassia, in coarse powder, Ibj; Proof Spirit Oij. Macerate for two days in a covered vessel, add a pint and a half of water, and distil off seven pints.)—Dose f5j to f5iv. It is usually prepared by adding oil of cassia to proof spirit.

4. TINCTURA CASSIE, E.; Tincture of Cassia.—(Cassia, in moderately fine powder, 3ijss; Proof Spirit Oij. Digest for seven days, strain, express the residuum strongly, and filter. This tincture is more conveniently made by the process of percolation, the cassia being allowed to macerate in a little of the spirit for twelve hours before being put into the percolator.)—Dose f5j to f5ij. Used as an adjuvant to tonic infusions.

Laurus Camphora, Linn.

(Sect. Syst. Enneandria, Monogynia.

(Concretum e ligno sublimatione comparatum, purificatum, L.—Camphor, E. D.)

History.—The ancient Greeks and Romans do not appear to have been acquainted with camphor. C. Bauhin and several subsequent writers state that Aetius speaks of it; but I have been unable to find any notice of it in his writings; and others have been equally unsuccessful in their search for it. Avicenna and Serapion call it cásfur; the latter erroneously cites Dioscorides. Symeon Seth, who lived in the 11th century, describes it, and calls it ξαφόρφα (the name by which it is designated in the Pharmacopœia Graeca, 1837); and his description is considered, both by Voigtels and Sprengel, to be the earliest on record.

Botany. Gen. Char.—Flowers hermaphrodite, panicled, naked. Calyx 6-cleft, papery, with a deciduous limb. Fertile stamens 9, in 3 rows; the inner with 2, stalked, compressed glands at the base; anthers 4-celled, the outer turned inwards, the inner outwards. 3 sterile stamens, shaped like the last, placed in a whorl alternating with the stamens of the second row; 2 others stalked, with an ovate, glandular head. Fruit placed on the obconical base of the calyx. Leaves triple-nerved, glandular in the axils of the principal veins. Leaf-buds sealy ( Lindley).

Sp. Char.—Leaves triple-nerved, shining above, glandular in the axils of the veins. Panicles axillary and terminal, corymbose, naked.

Flowers smooth on the outside (Nees). Young branches yellow and smooth. Leaves evergreen, oval, acuminate, attenuate at the base, bright green and shining above, paler beneath. Petioles from 1 to 1½ inches long. Panicles axillary and terminal, corymbose. Flowers small, yellowish-white. Berry round, blackish-red, size of a black currant. Seed solitary.

Every part of the tree, but especially the flower, evinces by its smell and taste that it is strongly impregnated with camphor.

Hab.—China, Japan, and Cochin-China. Introduced into Java from Japan.

Extraction and Description.—Two kinds of unrefined or crude camphor (Camphora crude vel rudis) are known in commerce; one is the produce of Japan, the other of China.

1. Japan Camphor.—This is always brought to Europe by the Dutch, and is, therefore, called Dutch camphor.

Kempfer and Thunberg have described the method of extracting this kind of camphor in the provinces of Satzuma, and the islands of Gothen in Japan. The roots and wood of the tree, chopped up, are boiled with water in an iron vessel, to which an earthen head, containing straw, is adapted. The camphor sublimes and condenses on the straw.

Japan or Dutch camphor is brought to Europe by way of Batavia. It is imported in tubs (hence it is called tub camphor) covered by matting, and each surrounded by a second tub, secured on the outside by hoops of twisted cane. Each tub contains from 1 cwt. to 1¼ cwts. or more. It consists of pinkish grains, which, by their mutual adhesion, form various-sized masses. It differs from the ordinary crude camphor in having larger grains, in being cleaner, and in subliming (usually) at a lower temperature. In consequence of these properties, it generally fetches 10s. per cwt. more. There is not much brought to England, and of that which does come the greater part is re-shipped for the continent.

6 De aliment. facult.
7 Hist. de la Méd. t. ii. p. 225.
8 Fl. Japonica.
2. China Camphor; Formosa Camphor.—This is the ordinary crude camphor.

The method of obtaining crude camphor in China has been described by the Abbé Grosier, Dentrecelles, and Davis. The chopped branches are steeped in water, and afterwards boiled, until the camphor begins to adhere to the stick used in stirring. The liquid is then strained, and, by standing, the camphor concretes. Alternate layers of a dry earth, finely powdered, and of this camphor, are then placed in a copper basin, to which another inverted one is luted, and sublimation effected.

This kind of crude camphor is imported from Singapore, Bombay, &c., in square chests lined with lead-foil, and containing from 1 1/2 to 1 3/4 cwt. It is chiefly produced in the island of Formosa, and is brought by the Chin-Chew junks in very large quantities to Canton, whence foreign markets get supplied. It consists of dirty grayish grains, which are smaller than those of Dutch camphor. Its quality varies; sometimes it is wet and impure, but occasionally it is as fine as the Dutch kind.

Refinement.—Crude camphor is refined by sublimation. Formerly, this process was carried on only at Venice. Afterwards, it was successfully practised in Holland. The method at present adopted in this metropolis is, as I am informed, as follows: The vessels in which this sublimation is effected are called bomboloes (bombola, Ital. βομβολά). They are made of thin flint glass, and weigh about 1 lb. each. Their shape is that of an oblate spheroid, whose shorter or vertical axis is about ten inches, and the longer or horizontal axis about twelve inches. They are furnished with a short neck. When filled with crude camphor, they are imbedded in the sand-bath, and heated. To the melted camphor lime is added, and heat raised so as to make the liquid boil. The vapour condenses on the upper part of the vessel. As the sublimation proceeds, the height of the sand around the vessel is diminished. In about forty-eight hours the process is usually completed. The vessels are then removed, and their mouths clothed with tow; water is sprinkled over them by watering-pots, by which they are cracked. When quite cold, the cake of camphor (which weighs about eleven pounds) is removed, and trimmed by paring and scraping. In this process the lime retains the impurities and a portion of the camphor; hence, to extract the latter, the lime is submitted to a strong heat in an iron pot with a head to it, and the sublimed product refined by a second sublimation.

Properties.—Refined Camphor (camphora raffinata vel elaborata; camphora, officin.) is met with in the form of large hemispherical or convex-concave cakes, perforated in the middle. It is translucent, has a crystalline granular texture; a strong, peculiar, not disagreeable, aromatic odour, and an aromatic, bitter, afterwards cooling taste. It is solid at ordinary temperatures, soft, and somewhat tough, but may be readily powdered by the addition of a few drops of rectified spirit. It evaporates in the air at ordinary temperatures; but in closed vessels, exposed to light, sublimes and crystallizes on the sides of the bottle. It burns in the air like the volatile oils generally. It fuses at 347° F., and forms a transparent liquid, which boils at 400° F., and in close vessels condenses unchanged. It is lighter

---

1 Hist. Gén. de la Chine, t. xiii. p. 335.
4 Ferber (Journ. de Pharm. t. i. p. 136, 1815) has described the refining process as practised by the Dutch.
5 Dossie, in his Elaboratory Iaid Open, 1706, has described the mode of refining camphor.
6 Clemandot (Journ. de Pharm. t. iii. p. 221, 1817) has described and figured another sort of subliming apparatus. 2 lb. of crude camphor, mixed with 6 drachmas of powdered quick lime, are placed in a flat-bottomed square bottle, with a short neck, on a sand-bath; the neck of the bottle fits into a conical tin-plate head, into which the camphor is sublimed.
7 A crystal of native camphor in the wood (probably not laurel camphor, but Borneo or dryobalanops camphor) in the collection of Materia Medica at the College of Physicians, appears as a flat octahedron, but its primary form is that of a rhombic prism (W. Phillips, in Paris's Pharmacologia).
than water, its sp. gr. being 0.9867; or, according to some, 0.996. Small pieces, when thrown on this liquid, are violently agitated, and present a gyratory motion, which ceases directly a drop of oil is let fall on the water. If a cylinder of camphor, of the 4th or 4th of an inch in diameter, be placed vertically in water, it communicates a to-and-fro movement to this liquid, and, in a few days, becomes cut through at the surface of the water. These phenomena are due to the simultaneous evaporation of the camphor and water, and which is most active where the two bodies are in contact.

Camphor is but very slightly soluble in water; 1000 parts of the latter dissolving only one part of camphor at the ordinary pressure of the atmosphere. But under augmented pressure it becomes more soluble.

Alcohol readily dissolves camphor; but if water be added to the solution, the camphor is precipitated. Ether, bisulphuret of carbon, the oils (both fixed and volatile), and the acids, also dissolve it. The liquid obtained by dissolving camphor in nitric acid is sometimes termed camphor oil: it is a nitrate of camphor, and is decomposed by water, the camphor being precipitated. The camphor absorbs sulphurous and hydrochloric acid gases, with which it unites and forms respectively a sulphite and a hydrochlorate of camphor. Camphor is insoluble in alkaline solutions. The vapour of camphor passed over red-hot lime is converted into naphthaline, and an oily liquid called camphrone.

Composition.—Camphor has the following composition:

Dumas has suggested that camphor may be regarded as an oxide of a base (as yet hypothetical) which he calls camphogen, and whose composition is C\(^{10}\)H\(^{8}\).

Chemical Characteristics.—In its combustibility, volatility, powerful odour, solubility in alcohol and ether, and almost insolubility in water, camphor agrees with the volatile oils. Being concrete or solid at ordinary temperatures, it obviously belongs to the class of stearopfenes, or solid volatile oils.

It is further distinguished by the remarkable character of its odour, by its not blackening in burning, and by its not being converted into resin by the oxygen of the air or by nitric acid. By repeatedly distilling nitric acid from camphor, the latter is converted into camphoric acid \(\text{C}^{10}\text{H}^{10}\text{O}_2\text{H}_2\text{O}\). Before the whole of the camphor has been converted into camphoric acid, there are produced intermediate compounds of camphor and this acid, which we may regard as camphorates of camphor.

The camphor which we have now described may be designated common or laurel camphor, in order to distinguish it from Borneo camphor, or camphor of the Dryobalanops, as well as from artificial camphor (see ante, p. 294).

Common or laurel camphor absorbs hydrochloric acid gas, and forms a transparent, colourless liquid; Borneo camphor, on the contrary, is scarcely acted on by this acid gas. If Borneo camphor be boiled in nitric acid, it is converted into common camphor.

Artificial camphor (see ante, p. 294) usually evolves some hydrochloric acid when volatilized, and burns in the air with a greenish sooty flame: if the flame be blown out, the evolved vapour has a terebinthinate odour. By these characters, artificial camphor may be distinguished from laurel camphor.

Oil of Laurel Camphor.—Pelouze and Freney state that when the branches of Camphora Officinarum are distilled with water, a mixture of camphor and a liquid essential oil is obtained, which is called oil of camphor.—This oil has a density of 0.910: its composition is C\(^{20}\)H\(^{16}\)O.
LAUREL CAMPHOR:—ITS PHYSIOLOGICAL EFFECTS.

By exposure to oxygen gas, or to the action of nitric acid, it absorbs oxygen and becomes solid camphor, \( \text{C}_{10}\text{H}_{16}\text{O}_{2} \). It is probable, therefore, that its formation precedes that of solid camphor in the camphor tree. I have met with this oil in commerce under the name of oil of camphor. By keeping, it deposits crystals of camphor, and, from this circumstance, may be distinguished from the oil of Borneo camphor (see Dryobalanops). By the action of hydrochloric acid, I find that these crystals liquefy, like common or laurel camphor. A considerable quantity of the oil was purchased some years ago by a London manufacturer of scented soap, who submitted it to distillation, and obtained from 60 lbs. of it, 40 lbs. of colourless liquid oil, and 20 lbs. of crystal-line camphor. The oil has been described and analyzed by Dr. Th. Martinus.1

PHYSIOLOGICAL EFFECTS. a. On Vegetables—Géppert2 has satisfactorily shown—first, that solutions of camphor act in the same deleterious manner on plants as the volatile oils; secondly, that they destroy the mobility of contractile parts without previously exciting them; thirdly, that they have no influence either on the germination of phanerogamia, or the vegetation of the cellular cryptogamia; and fourthly, that the vapour only is sufficient to destroy fleshy plants and ferns. Miquet3 has confirmed these results.

b. On Animals generally.—The action of camphor on animals has been the subject of numerous experiments made by Hillefeld,4 Monro,5 Menghini and Carminati,6 Viborg, Hertwich,7 Orfila,8 and Scudery.9

Air impregnated with the vapour of camphor proves injurious to insects (the Tinere, which destroy wool, excepted). Sooner or later it causes frequent agitation, followed by languor, insensibility, convulsions, and death (Menghini). To amphibials (frogs) the vapour also proves noxious. It produces preternatural movements, difficult respiration, trembling, and stupor (Carminati). Given to birds and mammals, in sufficient doses, camphor proves poisonous; but the symptoms which it gives rise to do not appear to be uniform. Indeed, there are few remedies whose action on the animal economy is so variable as that of camphor. Three drachms dissolved in oil and given to a dog, the oesophagus being tied, caused violent convulsions, somewhat analogous to those of epilepsy, followed by insensibility and death (Orfila). When administered in substance, it inflamed the digestive tube, caused ulceration, and, after its absorption, gave rise to convulsions (Ibid.). Given to horses, in doses of two drachms, it excites spasmodic movements, and quickens the pulse, but does not determine any serious result.10 Tiedemann and Gimlin11 detected the odour of camphor in the blood of the vena portæ and of the mesenteric vein of a horse to whom they had given camphor; but they could recognize it neither in the chyle nor in the urine. It is evolved from the system principally by the bronchial surfaces; for the breath of animals to which this substance has been administered has a strong odour of camphor. Moiroud12 observed that the skin of a horse, into whose jugular vein camphor had been injected, smelt of this substance.

"The general sedative effects of camphor on animals are rarely well marked; however, when administered in a proper dose, and in cases really requiring its use, it sometimes causes a diminution in the force and frequency of the pulse, and seems to allay pain" (Moiroud).

Scudery13 observed that the convulsions caused in animals by camphor were accompanied with a peculiar kind of delirium, which caused them to run up and down without apparent cause. He also found the urinary organs generally affected, and for the most part with strangury.

γ. On Man.—No article of the materia medica has had more contradictory state-

11 Quoted by Dr. Christison.
ments made respecting its effects and mode of action than camphor. These, however, have principally referred to its influence over the functions of circulation and calorification; for, with regard to the modifications which it induces in the other functions, scarcely any difference of opinion prevails.

Its local action on the mucous surfaces, the denuded dermis, and ulcers, is that of an acrid. A piece of camphor held in the mouth for half an hour caused the mucous lining of this cavity to become red, hot, swollen, and painful; and it is highly probable that, had the experiment been persevered in, ulceration would have followed. The pain and uneasiness which camphor, when swallowed in substance, sometimes produces in the stomach, are likewise imputed to its local action as an acrid. Rubbed on the skin covered with cuticle, Dr. Cullen says that it causes neither redness nor other mark of inflammation; but Dr. Clutterbuck declares this to be "undoubtedly a mistake." When applied to the denuded dermis, or to ulcers, it produces pain, and appears to act as an irritant. These observations respecting the local action of camphor on man are confirmed by the ascertained effects of this substance on other animals.

Camphor has been charged with producing brittleness of the teeth when it has been used for a considerable time as a dentifrice, but I believe without any valid foundation.

Camphor becomes absorbed, and is thrown out of the system by the bronchial membrane principally, but also by the skin. Trousseau and Pidoux recognized its odour in every case in the pulmonary exhalation, but failed to detect it in the cutaneous perspiration. Cullen, however, says that "Mr. Lasonne, the father, has observed, as I have done frequently, that camphor, though given very largely, never discovers its smell in the urine, whilst it frequently does in the perspiration and sweat." The non-detection of it in the urine agrees with the observation of Tielemann and Gmelin with regard to horses, already noticed.

Camphor specifically affects the nervous system.—Regarding the symptoms of this effect, but little difference of opinion prevails. In moderate doses, it exhilarates and acts as an anodyne. Its exhilarating effects are well seen in nervous and hypochondriacal cases (see vol. i. p. 237). In large doses, it causes disorder of the mental faculties, the external senses, and volition; the symptoms being lassitude, giddiness, confusion of ideas and disordered vision, noise in the ears, drowsiness, delirium or stupor, and convulsions. These phenomena, which have been observed in several cases, agree with those noticed in experiments on brutes. In its power of causing stupor, camphor agrees with opium; but it differs from the latter in its more frequently causing delirium and convulsions. Epilepsy has been ascribed to the use of camphor.

The quality of the influence which camphor exercises over the vascular system has been a subject of much contention. From my own limited observations of its use in small or medium doses (from five to ten grains), I am disposed to regard its leading effect as that of a vascular excitant, though I am not prepared to deny that slight depression may not have preceded this effect. Combined with diaphoretic regimen (warm clothing and tepid diluents), I have seen camphor increase the fulness of the pulse, raise the temperature of the surface, and operate as a sudorific. If opium be conjoined, these effects are more manifest.

In excessive doses, it acts as a powerful poison. The best related case is that of Mr. Alexander, who swallowed two scrupules in syrup of roses. In about twenty minutes, he experienced lassitude and depression of spirits, with frequent yawnings:

1 Trousseau and Pidoux, Traité de Thérap. t. i. p. 43.
5 Op. supra cit. p. 49.
7 See p. 427, for some remarks on the comparative operation of ammonia and camphor.
8 Experimental Essays, p. 128, 1768.
at the end of three-quarters of an hour his pulse had fallen from 77 to 67. Soon after he felt giddy, confused, and almost incapable of walking across the room. He became gradually insensible, and in this condition was attacked with violent convulsions and maniacal delirium. From this state he awoke as from a profound sleep; his pulse was 100, and he was able to reply to interrogatories, though he had not completely recovered his recollection. Warm water being administered, he vomited up the greater part of the camphor, which had been swallowed three hours previously; and from this time he gradually recovered.

In another case, a man swallowed four ounces of camphorated spirits containing 160 grains of camphor. The symptoms were burning heat of skin, frequent, full, and hard pulse, brilliancy of the eyes, redness of the face, heaviness of the head, anxiety, agitation, violent sense of heat in the stomach; then intense headache, giddiness, indistinctness of sight, and ocular hallucinations. The patient complained of heat only, which he said was intolerable. In the night, copious sweating came on, followed by sleep. The pulse continued full and frequent, and the voiding of urine difficult.

In some other well-reported cases, camphor, in large doses, caused depression of the vascular system. In the instance related by Fréd. Hoffmann, Pouteau, Griffin, Cullen, Callisen, Edwards, and Trousseau and Pidoux, sedation of the vascular system was observed. It was manifested by a languid, small, and slower pulse, coldness of the surface, and pallid countenance; in some cases with cold sweat. In some of these instances, symptoms of vascular excitement followed those of depression. The pulse became more frequent and fuller than natural, and the heat of the surface augmented. Trousseau and Pidoux ascribe the symptoms of sedation to the depressing influence which camphor exerts over the system by sympathy; while the sanguineous excitation they refer to the passage of camphor into the blood, and the efforts of the organism to eliminate this unassimilable principle. But in some of the cases in which excessive doses of camphor have been taken, no symptoms of depression were manifested; as in the instance mentioned by Dr. Eickhorn (in whom great heat, rapid but small pulse, copious sweating, and agreeable exhilaration, were produced by 120 grains), by Dr. Wendt, by Scudery, and by Bergondi.

Camphor has long been celebrated as an anaphrodisiac; the smell of it even is said to be attended with this effect; hence the verse of the School of Salernum—"Camphora per naves castrat odore mares." Trousseau and Pidoux experienced the anaphrodisiac property of 36 grains of camphor taken into the stomach.

Strangury has also been ascribed to this substance by Heberden, Scudery, and others.

Uses.—The discrepancy among authors as to the physiological effects of camphor has had the effect of greatly circumscribing the use of this substance. Indeed, until its operation on the system be more satisfactorily ascertained, it is almost impossible to lay down general rules which should govern its exhibition. The following are the principal maladies in which it has been found useful:

1. Fever.—Camphor has been employed in those forms of fever which are of a typhoid type. It is chiefly valuable by causing determination to the surface, and giving rise to diaphoresis. Hence those remedies should be conjointed with it which promote these effects: such as ipecacuanha, emetic tartar, and the vegetable alkaline salts. Opium greatly contributes to the sudorific effects of camphor; and, when it is admissible, benefit is sometimes obtained by the administration of one
grain of opium with five or eight of camphor. But in a great number of cases of fever, the cerebral disorder forbids the use of opium. From its specific influence over the cerebral functions, camphor has been frequently used in fever to allay the nervous symptoms—such as the delirium, the watchings, the subsultus tendinium, &c.; but it frequently fails to give relief. Dr. Home did not find any advantage from its use in the low nervous fever; and Dr. Heberden has seen one scruple of camphor given every six hours, without any perceptible effect in abating the convulsive catchings, or composing the patient to rest.

2. In inflammatory diseases.—In the latter stages of inflammation of internal important parts (as the serous and mucous membranes, the stomach, intestines, uterus, &c.), after proper evacuations had been made in the earlier periods of the disease, when great exhaustion is manifested by a small feeble pulse and a cold flaccid skin, small but repeated doses of camphor have been employed to determine to the skin, and to promote diaphoresis. It is particularly serviceable in rheumatic inflammation, and especially when produced by metastasis.

3. In the exanthemata.—Camphor has been employed in smallpox, as also in measles, scarlatina, and miliary fever: but it is admissible only when the circulation flags, and the temperature of the surface falls below the natural standard. In such cases it is sometimes employed along with a diaphoretic regimen to determine to the skin. It is to be carefully avoided when inflammation of the brain or its membranes is feared. It has been asserted that if a camphorated ointment be applied to the face, no smallpox pustules will make their appearance there; but the statement is not correct.

4. In mania, melancholia, and other forms of mental disorder.—Camphor is occasionally taken to cause exhilaration. I am acquainted with two persons (females), both of nervous temperament, who use it for this purpose. To relieve despondency I have often found it serviceable. In mania and melancholia, it has now and then proved serviceable by its narcotic effects: it induces mental quiet, and causes sleep. It was used in these affections by Paracelsus and several succeeding writers, especially, in more modern times, by Dr. Kinneir; and by Avenbrugger. The latter regards it as a specific in the mania of men, when accompanied with a small contracted penis, corrugated empty serum, or when both testicles are so retracted that they appear to be introduced into the abdominal cavity.

5. In spasmodic affections.—The narcotic influence of camphor has occasionally proved serviceable in some spasmodic or convulsive affections; viz., spasmodic cough, epilepsy, puerperal convulsions, hysteria, and even tetanus: its use, however, requires caution.

6. In irritation of the urinary or sexual organs.—A power of diminishing irritation of the urinary organs has long been assigned to camphor. In strangury and dysuria, especially when produced by cantharides, it is said to have been used with benefit—a statement apparently inconsistent with that more recently made of its producing irritation of the urinary organs. In satyriasis, nymphomania, and onanism, it is said to have proved advantageous by its anaphrodisiac properties. In dysenorrhœa, it sometimes proves serviceable as an anodyne.

7. In poisoning.—Small doses of camphor (administered by the mouth or by the rectum) have been exhibited with apparent benefit in cases of poisoning by opium. It has also been employed to mitigate the effects of cantharides, squills, and mezereon; but toxicologists, for the most part, do not admit its efficacy: at any rate, further evidence is required to establish it. Nor does there appear any valid testimony for believing that camphor possesses the power of checking mercurial salivation, as some have supposed.

8. In chronic rheumatism and gout.—A mixture of camphor and opium, in the
Camphor Mixtures.

proportions before mentioned, is useful in chronic rheumatism, by its sudorific and analgesic properties. Warm clothing and diluents should be conjoined. In chronic gout, also, camphor is said to have proved beneficial.

9. In cholera.—The combination of camphor and opium above referred to, I have seen used with benefit in cholera.

10. Externally, camphor is employed in the form of vapour, in solution, or, more rarely, in the solid state. The vapour is occasionally inhaled in spasmodic cough; and is applied to the skin to alleviate pain and promote sweat, constituting the camphor fumigations (fumigationes camphorae). Dupasquier\(^1\) recommended these fumigations in chronic rheumatism. The patient may be in bed or seated in a chair; and, in either case, is to be enveloped by a blanket tied round the neck. About half an ounce of camphor is then to be placed on a metallic plate, and introduced within the blanket (under the chair, if the patient be seated). In solution, camphor is used either as an anodyne or a local stimulant. The nitric solution of camphor is used to relieve toothache. A solution of camphor in oil has been used as an injection into the urethra, to relieve ardor urinae in gonorrhoea, and into the rectum to mitigate tenesmus arising from ascariides or dysentery. The acetic and alcoholic solutions of camphor are mostly employed as stimulants. In substance, camphor is not frequently used. A scruple or half a drachm "added to a poultice, and applied to the perineum, allays the chordee, which is a painful attendant upon gonorrhoea."\(^2\) Powdered camphor is a constituent of some tooth-powders, to which it communicates its peculiar odour.

The foregoing are some only of the maladies in which camphor has been extensively used and lauded. I must refer to the works of Murray\(^3\) for various other uses which have been made of this substance. It is scarcely necessary to add that camphor-bags possess no prophylactic properties against contagion.

Administration.—The medium dose of it is from five to ten grains; but it is frequently exhibited in much smaller doses (as one grain); and occasionally a scruple has been employed. It is given in the form of a pill or emulsion. That of pill is said to be objectionable, "as in this state the camphor is with difficulty dissolved in the gastric liquors, and, floating on the top, is apt to excite nausea, or pain or uneasiness at the upper orifice of the stomach."\(^4\) It has been charged with causing ulceration of the stomach when given in the solid form. The emulsion is made by rubbing up the camphor with loaf sugar, gum Arabic, and water; and the suspension will be rendered more complete by the addition of a little myrrh.\(^5\)

Antidote.—In a case of poisoning by camphor, first evacuate the contents of the stomach. Hufeland\(^6\) recommends the use of opium to relieve the effects of camphor. Phebus\(^7\) directs chlorin water to be administered as the antidote, and afterwards purgatives and clysters. Vinegar and coffee, he states, promote the poisonous operation. Wine assists the patient's recovery.

1. MISTURA CAMPHORÆ, L. E. D.; Aqua Camphoræ [U. S.]; Camphor Mixture; Camphor Water.—(Camphor 5 ss; Rectified Spirit m x; Distilled Water 0 j. First rub the camphor with the spirit, then with the water gradually poured in, and strain through linen, L.—The Dublin College orders of Tincture of Camphor f 5 j; Water Oij. Shake the tincture and water together in a bottle, and, after the mixture has stood for twenty-four hours, filter through paper. The Edinburgh College employs Camphor 0 j.; Sweet Almonds and Pure Sugar, of each 5 ss; Water Oij. Steep the almonds in hot water, and peel them; rub the camphor and sugar well together in a mortar; add the almonds; beat the whole into a smooth pulp; add the water gradually, with constant stirring, and then strain, E.)—The camphor mixture kept in the shops is often prepared by suspending camphor in water without the intervention of any third body. The quantity of this substance dissolved

---

3. Ibid.
5. United States Dispensatory.
is exceedingly small. The rectified spirit employed by the London and Dublin Colleges serves to promote the pulverization, and, very slightly, perhaps, the solution of the camphor. Sugar also assists its diffusion through water. The preparation of the Edinburgh Pharmacopoeia is, in fact, an emulsion.—[The Aqua Camphor of the U. S. Pharm. is thus prepared: Camphor two drachms; Alcohol forty minims; Carbonate of Magnesia a drachm; Distilled Water two pints. Rub the camphor first with the alcohol, afterwards with the carbonate of magnesia, and lastly with the water gradually added; then filter through paper.]—None of these artificial mixtures, however, are very permanent, and the quantity of camphor which remains in solution is so small that the liquid can scarcely be said to possess more than the flavour and odour of camphor. Hence its principal value is as a vehicle for the exhibition of other medicines. Its usual dose is from $\frac{f}{3}$ j to $\frac{f}{3}$ ij.

2. MISTURA CAMPHORÆ CUM MAGNESIA, E.; Camphor Mixture with Magnesia.—(Camphor gr. x; Carbonate of Magnesia gr. xxy; Water $f$ $\frac{3}{2}$ vj. Triturate the camphor and carbonate of magnesia together, adding the water gradually.)—The carbonate of magnesia promotes the solution of the camphor in water. This mixture, therefore, holds a larger quantity of camphor in solution than the previous one. A minute portion of magnesia is also dissolved. As the magnesian carbonate is not separated by filtration, it gives to the mixture antacid properties, in addition to those qualities which this preparation derives from the camphor. In addition to the uses of the simple camphor mixture, this preparation has been found very beneficial in the uric acid diathesis, and also in irritations of the neck of the urinary bladder, particularly when given in combination with hyoscyamus. The dose is from $f$ ss to $f$ j.

Murray's Fluid Camphor.—This is a solution of camphor in fluid magnesia (see vol. i. p. 592). Each ounce contains three grains of camphor and six grains of bicarbonate of magnesia. Its sp. gr. is 1.0026.

3. SPIRITUS CAMPHORÆ, L.; Tinctura Camphoræ, E. D. [U. S.]; Spiritus Camphoratus; Spirit of Camphor; Camphorated Spirits of Wine, offic.—(Camphor $\frac{3}{4}$ v [$\frac{3}{4}$ iv, U. S.], $\frac{3}{3}$ ij, in small fragments, D.; $\frac{3}{4}$ iss, E.); Rectified Spirit Oij [Alcohol Oij, U. S.], $\frac{1}{2}$ viij, D.]. Dissolve.—The principal use of this preparation is as a stimulant and aodyne liniment in sprains and bruises, chilblains, chronic rheumatism, and paralysis. Water immediately decomposes it, separating the greater part of the camphor, but holding in solution a minute portion; thereby forming an extemporaneous camphor mixture. By the aid of sugar or mucilage, the greater part of the camphor may be suspended in water. Employed in this form, we may give tincture of camphor internally, in doses of from $m$ x to $f$ j.

"Spiritus camphorae is miscible with liquor plumbi diaeastic in the proportion of two parts of the former to one of the latter, and in this form it is a convenient preparation, sometimes ordered as a concentrated lotion, to which water is to be added by the patient. But if a larger proportion of liquor plumbi be added, the camphor is partially precipitated."

4. TINCTURA CAMPHORÆ COMPOSITA, L.; Compound Tincture of Opium; Tinctura Opii camphorata, E. D. [U. S.]; Elixir Purgoricum; Purgoric Elixir, offic.—(Camphor $\frac{3}{4}$ iss [$\frac{3}{4}$ j, D.]; Opium, powdered [sliced, E.], gr. lxxij [$\frac{3}{4}$ iss, D., $\frac{3}{4}$ iv, E.]; Benzoic Acid gr. lxxij [$\frac{3}{4}$ iv, E., $\frac{3}{4}$ iss, D.]; Oil of Anise [$\frac{3}{4}$ ]; Proof Spirit Oij. Macerate for seven days, and filter.)—This is a very valuable preparation, and is extensively employed both by the public and the profession. Its active ingredient is opium. The principal use of it is to allay troublesome cough unconnected with any active inflammatory symptoms. It diminishes the sensibility of the bronchial membrane to the influence of cold air, checks profuse secretion, and

1. Dr. Montgomery, Observ. on the Dubl. Pharm.
allays spasmodic cough. Dose, $\frac{3}{4}$ij to $\frac{3}{4}$ij. A fluidounce contains nearly two grains of opium. The name given to this preparation by the London College, though less correct than that of the Edinburgh and Dublin Colleges, is, I conceive, much more convenient, since it enables us to prescribe opium without the knowledge of the patient—no mean advantage in cases where a strong prejudice exists in the mind of the patient or his friends to the use of this important narcotic. Furthermore, it is less likely to give rise to serious and fatal errors in dispensing. In a case mentioned by Dr. M. Good, laudanum was served, by an ignorant dispenser, for tinct. opii camph. The error proved fatal to the patient. [For the formula of the U. S. Pharm., see Preparations of Opium.]

5. LINIMENTUM CAMPHORI. L. E.; Oulem Camphoratum, D.; Camphor Liniment, offic.—(Camphor $\frac{3}{4}$j [5j, D.]; Olive Oil $\frac{3}{4}$iv [5j, D.].) Shake them together until they are mixed, L. Rub them together [in a mortar, E.], until the camphor is dissolved, E. D.)—A stimulant and anodyne embrocation in sprains, bruises, and rheumatic and other local pains. In glandular enlargements, it is used as a resolvent.

6. LINIMENTUM CAMPHORI COMPOSITUM, L. D.; Compound Liniment of Camphor.—(Camphor $\frac{5}{3}$jss [5v, D.]; Olive Lavender $\frac{3}{4}$j [2j, D.]; Rectified Spirit $\frac{2}{3}$xvij [Oiss, D.]; Stronger Solution of Ammonia $\frac{5}{3}$ijj [Oss, D.].) Dissolve the camphor and oil in the spirit; then add the ammonia, and mix with agitation.)—A powerful stimulant and rubefacient, producing, when freely used, considerable irritation and inflammation. It is applicable in the same cases as the simple camphor liniment and the liniment of ammonia (vol. i. p. 433). From both of these compounds it differs in not being greasy. “I have used,” says Dr. Montgomery, “a liniment composed of two parts of this and one of turpentine, with children, as a substitute for a blister, and with good effect; or, with equal parts of the anodyne liniment, I have found it highly beneficial in the removal of those distressing pains in the back which so frequently annoy women about the close of their pregnancy.

143. SASSAFRAS OFFICINALE, Nees.—THE SASSAFRAS TREE.

Laurus Sassafras, Linn.

Sex. Syst. Enneandria, Monogynia. (Radix, L.—The Root, E. D.)

History.—Sassafras wood is mentioned by Monardes, who states that it had been recently introduced into Spain from Florida. It was, however, first brought to Europe by the French.

Botany. Gen. Char.—Dioecious. Calyx 6-parted, membranous; segments equal, permanent at the base. MALES: Fertile stamens 9, in 3 rows, the 3 inner with double-stalked distinct glands at the base. Anthers linear, 4-celled, all looking inwards. FEMALES with as many sterile stamens as the male, or fewer; the inner often confluent. Fruit succulent, placed on the thick fleshy apex of the peduncle, and seated in the torn unchanged calyx.—Flowers yellow, before the leaves. Leaves deciduous (Lindley).

Sp. Char.—Leaves thin, oblong, entire, 2—3-lobed. A small tree, or bush. Leaves smooth above, finely downy beneath. Racemes with subulate downy bracts.

Hab.—Woods of North America, from Canada to Florida.

Description.—The root (radix sassafras) is used in medicine. Its bark (cor tex radicis sassafras vel cortex sassafras) occurs in rather small pieces, which

---

1 Hist. of Med. 1795, App. p. 11.  
are light, odorous, not fibrous, but spongy or corky. The epidermis is brownish-gray: the cortical layers and inner surface reddish cinnamon brown, or almost rust-red, becoming darker by age. Sometimes small, white, micaceous crystals (like those found on sassafras nuts) are observed on the inner surface of the bark. Sassafras wood (lignum radicis sassafras vel lignum sassafras) occurs in the form of large stems or branches, frequently more or less covered with the bark. The wood is soft or spongy, light, of a grayish-reddish tint, and has a fragrant aromatic odour. It is usually sold cut up into chips: sassafras chips.

**Brazilian Sassafras:** Pêdo Sassafras.—This is the produce of Nectandra cymbarum of Nees, the Ooea amara of Martius. It grows in Rio Negro. Its bark is bitter and aromatic, and is used as a tonic and carminative.

**Sassafras Nuts:** Pichurim Beans; Fabae Pichurim.—These seeds (or rather cotyledons) are the produce of Nectandra Pichury major of Nees, and Nect. Puchury minor of Nees, trees growing in the province of Rio Negro. They were imported from Brazil into Stockholm in the middle of the last century, and were found a valuable tonic and astringent medicine: during the continental war they were used as a bad substitute for nutmegs." They are still to be found in some of the old drug-houses of London. By keeping in a bottle, small micaceous crystals form on their surface. These seeds have been analyzed by Bonastre. Their aromatic qualities depend on a volatile oil.

**Composition.**—Neither the bark nor the wood have been analyzed. They contain volatile oil, resin, and extractive matter.

**Physiological Effects.**—The wood and the bark are stimulant and sudorific. Taken in the form of infusion, and assisted by warm clothing and tepid drinks, they excite the vascular system and prove sudorific. They owe their activity to the volatile oil, which possesses acrid properties.

**Uses.**—Sassafras is employed as a sudorific and alterative in cutaneous, rheumatic, and venereal diseases. On account of its stimulant properties it is inadmissible in febrile or inflammatory conditions of the system. It is rarely or never used alone, but generally in combination with sarsaparilla and guaiacum.

**Administration.**—Sassafras is administered in the form of oil or infusion. The dose of the oil is from two to ten drops. Sassafras tea, flavoured with milk and sugar, is sold at daybreak in the streets of London, under the name of saloop. Sassafras is a constituent of the Decoctum Sarzæ Compositum; but the volatile oil is dissipated by boiling (see ante, p. 279).

**Oleum Sassafras,** [U. S.]; Volatile Oil of Sassafras officinale, E.; Oil of Sassafras.—(Obtained by submitting the wood to distillation with water.) It is colourless, but, by keeping, becomes yellow or red. Its smell is that of sassafras; its taste hot. Sp. gr. 1.094. Water separates it into two oils; one lighter, the other heavier than water. By keeping, it deposits large crystals (stéaroptène; saffadol, C_{10}H_{16}O), which are readily soluble. Oil of sassafras is rendered orange-red by nitric acid. It is said to be adulterated with oil of lavender or oil of turpentine; but the statement, I suspect, does not apply to the oil found in English commerce. Oil of sassafras is stimulant and diaphoretic. It may be employed in chronic rheumatism, cutaneous diseases, and venereal maladies. It is a constituent of the Compound Extract of Sarsaparilla (see ante, p. 281).

**144. LAURUS NOBILIS,** Linn.—THE SWEET BAY.

**Sex. Syst.** Eneandria, Monogynia.

**(Fructus, L.)**

**History.**—The "green bay-tree" is mentioned, though erroneously in our translation of the Bible; the Hebrew word, translated bay, meaning native. Hippocrates used both the leaves and berries of the bay-tree (bayv) in medicine. Bay-leaf is analogous to the malabathrum of the ancients.  

---

3. *Psalms,* xxvii. 35, 39
BOTANY. Gen. Char.—*Flowers* dioecious or hermaphrodite, involucreted. *Calyx* 4-parted; segments equal, deciduous. *Fertile stamens* 12, in 3 rows; the outer alternate with the segments of the *calyx*; all with 2 glands in the middle or above it. *Anthers oblong, 2-celled, all looking inwards. Female flowers*, with 2 to 4 castrated males, surrounding the ovary. *Sigmoid* capitate. *Fruit* succulent, seated in the irregular base of the calyx.—*Umbels* axillary stalked. *Leaf-buds* with valvate papery scales. *Leaves* evergreen (Lindley).

Sp. Char.—The only species.

A *bush or small tree*. *Bark* aromatic, rather bitter. *Leaves* alternate, lanceolate, acute, or acuminate, wavy at the edge, somewhat coriaceous. *Flowers* yellowish. *Fruit* (called by Nees a 1-seeded flesh berry, by De Candolle, a drupe) bluish-black, oval, size of a small cherry. *Seed* pendulous; *funiculus* compressed, ascending from the base of the fruit, and attached at the top of the testa; testa papery; *tunica interna* very thin; *embryo* exalbuminous, composed of two large oleaginous *cotyledons* inclosing superiorly the *radicle*.

Hab.—South of Europe. Cultivated in gardens.

Description.—Bay leaves (*folia laurí*) have a bitter aromatic taste, and a somewhat aromatic odour. Their infusion reddens litmus. Dry *bay berries* (baccae laurí, offic.) are covered externally by a dark-brown brittle coat, which is produced by the epidermis and succulent covering of the fruit.

Composition.—In 1824, bay berries were analyzed by Bonastre,1 who found the constituents to be—Volatile oil 0.8, *laurin* 1.0, *fixed oil* 12.8, wax (stearin) 7.1, resin 1.6, uncrystallizable sugar 0.4, gummy extractive 17.2, bassorin 6.4, starch 25.9, woody fibre 18.8, soluble albumen traces, an acid 0.1, water 6.4, salts 1.5.

The ashes (amounting to 1.2) consisted of carbonate of potash and the carbonate and phosphate of lime.

1. Volatile Oil of Laurel Berries; Oil of Sweet Bay.—Obtained from the berries by distillation with water. The crude oil is pale yellow, transparent, readily soluble in alcohol and ether. By redistillation it yields two isomeric oils (C<sub>20</sub>H<sub>36</sub>O); one having a sp. gr. of 0.857, the other 0.855, while a brown balsamic matter remains in the retort.2

2. Laurin; Camphor of the Bay Berry.—A crystalline solid, fusible and volatile. Has an acrid bitter taste, and an odour analogous to that of the volatile oil. It is soluble in ether and insoluble in boiling alcohol. Sulphuric acid renders it yellow; nitric acid liquefies it. Alkalies are without action on it. It is extracted from bay berries by rectified alcohol.

3. Fixed Oil of Bays (see below).

Physiological Effects.—The berries, leaves, and oil are said to possess aromatic, stimulant, and narcotic properties. The leaves, in large doses, prove emetic.3

Uses.—Bay berries or leaves are rarely, if ever, used in medicine in this country. They might, therefore, with great propriety be expunged from the Pharmacopœia. The leaves are employed by the cook on account of their flavour. Both leaves and berries have been used to strengthen the stomach, to expel flatus, and to promote the catamenial discharge.

Administration.—Both berries and leaves are used in the form of infusion.

Oleum Laurí; Oleum Laurí expressum; Oleum Laurinum; Laurel Fat; Oil of Bays.—This may be obtained from either the fresh or dried berries. Duhamel4 states that it is obtained from the fresh and ripe berries by bruising them in a mortar, boiling them for three hours in water, and then pressing them in a sack. The expressed oil is mixed with the decoction, on which, when cool, the butyrous oil is found floating. From the dried berries it is procured by exposing them to the vapour of water until they are thoroughly soaked, and then rapidly subjecting them to the press between heated metallic plates. By the latter method they yield one-fifth of their weight of oil.5 Oil of bays is imported in barrels from Trieste.

---

1. *Journ. de Pharm.* x. 39.
VEGETABLES.—Nat. Ord. Lauraceæ.

In 1839, duty was paid on 1737 lbs. of it. It has a butyrateous consistence and a granular appearance. Its colour is greenish; its odour is that of the berries. It is partially soluble in alcohol, completely so in ether. With alkalies it forms soaps. It is occasionally employed externally as a stimulating liniment in sprains and bruises, and in paralysis. It has also been used to relieve colic, and against deafness. Its principal use, however, is in veterinary medicine.

OLEUM LAURI AMTHEREUM NATIVUM; Native Oil of Laurel, Hancock, Trans of the Medico-Bot. Society of Lond., p. 18, 1826; Laurel Turpentine, Stenhouse, Mem. of the Chemical Society, vol. i. p. 45, 1843.—Imported from Demerara: obtained by incision in the bark of a large tree, called by the Spaniards "Azete de Sassafras," growing in the vast forests between the Orinoco and the Parime. By Dr. Hancock this tree was thought to belong to the nat. ord. Lauraceæ; but Dr. Stenhouse thinks that it is a species of pine. The oil is transparent, slightly yellow, and smells like turpentine, but more agreeable, and approaching to the oil of lemons. Its sp. gr. at 50° F. is 0.8645. The commercial oil consists of two or more oils isomeric with each other and with oil of turpentine. C₃₀H₄₄O. Its yellow colour is due to a little resin. A volatile acid (formic acid?) is also present in very small quantity. In its medicinal qualities it resembles turpentine; being stimulant, diuretic, and diaphoretic. It has been used externally as a discutient in rheumatism, swellings of the joints, cold tumours, paralytic disorders, &c. It is an excellent solvent for caoutchouc.

145. NECTANDRA RODLÆI, Schomburgk.—THE BIBIRU OR GREENHEART TREE.

Sex. Syst. Dodecandrin, Monogynia.

(Cortex.)

History.—In 1769, Bancroft observed the valuable qualities of the wood of this tree, which he called the Greenheart or Sípeira. In 1834, Dr. Roder observed the bark was a good substitute for cinchona, and that both it and the fruit contained an alkaloid, which he used with great success in intermittents: he terms the tree the Bebecuru, and the alkaloid Bebecrinc. In 1843, Dr. Douglas Maclagan published an account of the chemical and therapeutical properties of the bark, and confirmed the discoveries of Dr. Roder. The following year a full botanical description of the tree, which he terms Bibiru, or Sípiri, was drawn up by Sir Robert Schomburgk, aided by Mr. Bentham.

Botany. Gen. Char.—Flowers hermaphrodite. Calyx 6-parted, rotate; segments deciduous, the 3 outer rather the broadest. Stamens 12, in 4 series; the 9 outer fertile, the 3 inner sterile; glands in pairs, globose, sessile, at the base of the 3 inner fertile stamens; the anthers in the first and second series turned inwards, those of the third series turned outwards, all ovate, nearly sessile with 4 cells arranged in a curve, and distinct from the tip of the anther, with as many ascending dehiscing valves; sterile stamens either tooth-shaped and biglandular at the base, or glandless, and then with a small ovule head. Ovary 1-celled, with 1 ovule in each cell. Style very short; stigma short and truncated. Berry 1-seeded, more or less immersed in the tube of the calyx changed into a truncated cup.—Trees of tropical America, with alternate, feather-veined leaves, and panicked or corymbose, axillary, lax, ample flowers (Endlicher).

Sp. Char.—Leaves nearly opposite, oblong-elliptical, shortly acuminate, coriaceous, smooth, shining, and obscurely netted on the upper side; panicles few-flowered,
The Bibiru or Greenheart Tree:—Description; Composition. 409

axillary, much shorter than the leaves, finely downy; anthers all thick oblong, without glands (Bentham).

A large forest tree, of 60 or more feet high, with a trunk frequently above 50 feet high, undivided by branches till near the top, and covered by an ash-gray smooth bark. Leaves 5 or 6 inches long, and 2 or 3 inches broad. Flowers yellowish-white. Berry somewhat obovate, globular, slightly compressed, the longer extension 7/ inches in circumference, the less about 6 inches: the pericarp grayish-brown, speckled with whitish dots, hard, very brittle, and about a line thick. Seed 1 in each fruit, about the size and shape of a walnut, and containing 2 large plano-convex cotyledons.

Hab.—British Guiana: on rocky hill-sides on the borders of rivers (the Essequibo, Cuyuni, Demerara, Pomeroon, Berbice, &c.).—The timber is used for ship-building, under the name of Greenheart.

Description.—Bibiru or beeberu bark (cortex bibiru), is derived from the trunk. It consists of large, flat, heavy pieces, from 1 to 2 feet long, from 2 to 6 inches broad, and about 3 or 4 lines thick. It is covered externally with a brittle grayish-brown epidermis. Internally, its colour is dark cinnamon-brown. The fracture is rough and somewhat fibrous. The taste is strong, persistent, bitter, with considerable astringency, but with aroma, pungency, or acridity.

The fruit (fructus bibiru) commonly called a nut, has been described above. The seeds (semina bibiru) yield starch, which is used as food by the Indians. A section of the cotyledons, when moist and fresh, was pale yellow, and became brown by exposure to the air. The juice had an acid reaction, and was intensely bitter.

Composition.—The bark and seeds have been analyzed by Dr. Maclagan, and his results are as follows:

1. Bibirina; Beeberina; Bibirite; Beberine, C9H10N2O4.—Obtained by decomposing commercial sulphate of bibirina by ammonia; the precipitate is washed with cold water, triturated while still moist with moist hydrated oxide of lead, and the magma dried on a water-leth, and exhausted by rectified spirit. In this way is obtained an alcoholic solution of bibirina and sipirina, while the oxide of lead, tannin, and other impurities are left behind. The alcohol is to be distilled off, and the resinous-looking residue treated with pure ether, which dissolves the bibirina, but leaves behind the sipirina. Bibirina is uncrystallizable. When obtained by evaporation from its ethereal solution, it is a yellow, amorphous, resinos-looking substance; but in the form of powder it is white. It is very soluble in alcohol, less so in ether, and very sparingly in water. Its alcoholic solution reacts as an alkali on reddened litmus paper. It dissolves in acids, and neutralizes them, forming amorphous yellow salts. Colourless or crystallized salts have not yet been procured. According to Maclagan and Tilley,1 its composition is identical with morphia. Winckler2 says, that bibirina resembles in many respects paracone, but differs from the latter in the circumstance of its hydrate being gelatinous.

2. Sipirina; Sipirina; Sipirina; Sipirina.—This substance, which Dr. Maclagan at first thought to be a second alkaloid, he now regards as a product of the oxidation of bibirina.

3. Bibiric Acid; Beeberic Acid.—A white, crystalline, deliquescent, volatile acid obtained from the seeds.

4. Starch.—I am indebted to Dr. Maclagan for some of the starch obtained from the seeds of this plant. It is grayish-white, and almost tasteless. When examined by the microscope, it is found to consist of particles which are somewhat smaller than those of cassava starch, but in their external form, quite agree with the latter. Schomburk states that the Indians are

2 Ibid. vol. vi. p. 693, 1847; also, Buchner's Report, 2ter Reihe, Bd. xlv. p. 231, 1816.
oblige to live for months on it. It is prepared by grating the seeds and immerasing them in water. Repeated washing he found did not deprive the starch of its bitterness. The starch mixed with decayed wood, chiefly of the Walaba tree (Eperna falkata), is baked into cakes. Winckler has discovered starch in the bark as well as in the seeds.

5. TANNIN.—This agrees very much with that found in the cinchona bark; and, like the latter, it yields a green colour with the salts of iron.

PHYSIOLOGICAL EFFECTS.—Bibiru bark appears to possess the tonic, antiperiodic, febrifuge, and astringent properties of cinchona barks. Like the latter, its bitter, tonic, and antiperiodic powers reside in a vegetable alkaloid; and its astringent property in that kind of tannic acid which strikes a green colour with the salts of iron.

Sufficient experience has not yet been obtained with bibiru bark and its alkaloid (bibirine), to enable us to form an accurate opinion of their therapeutical power in comparison with cinchona bark and quinia. In some cases, bibirina has appeared to produce its peptic and tonic effects with less tendency to cause headache, giddiness, ringing in the ears, and feverishness, than quinia; and it can in consequence be administered to some patients with whom quinia disagrees. On the other hand, it appears inferior to the latter in febrifuge and antiperiodic power.

USES.—Bibiru bark and bibirina (in the form of sulphate) have been used as a peptic in anorexia and dyspepsia; as a general tonic in debility, protracted phthisis, and strumous affections; as a febrifuge in intermittent and remittent diseases; and as an antiperiodic in periodical headache and intermittent neuralgias.¹

BIBIRINE SUBSULPHAS; Bebeerina Sulphas; Sub-sulphate of Bibirine; Sulphate of Bebeerine.—The process for obtaining this is essentially the same as that of the Edinburgh Pharmacopoeia for sulphate of quinia. The bark is first boiled with a solution of carbonate of soda to remove the tannin and colouring matter; it is boiled with water acidulated with sulphuric acid, by which sulphate of bibirine is obtained in solution. To the strained liquor carbonate of soda is added, and the impure bases thus thrown down washed, dissolved, and neutralized with sulphuric acid, and the solution decolorized by animal charcoal, concentrated, filtered, and finally evaporated in flat open vessels; excess of acid being avoided in order to prevent charring on evaporation.

There are two compounds of sulphuric acid and bibirina—the sulphate (BiSO₄) and the sub-sulphate (Bi₃SO₄): the latter is the commercial salt which has been prepared for medicinal use by Mr. Macfarlane, of Edinburgh:

<table>

</tr>
</tbody>
</table>

The sub-sulphate of bibirina (Macfarlane's basic commercial sulphate of bebeerine) is not absolutely pure. It contains sub-sulphate of sipirina, sulphate of lime, and colouring matter. It occurs in brownish-yellow, thin, glittering scales, which form a yellow powder, and by incineration leave a mere trace of ash only. It has a very persistent bitter taste. It is soluble in alcohol. It is slightly soluble in cold water, with which it yields a turbid solution, partly from the excess of base, partly from the decomposing tendency of the sipirina. Its solution in water is rendered more complete by a few drops of sulphuric acid.

Its effects and uses have already been alluded to.

It may be administered in doses of from one to three grains as a tonic, and from

¹ For further information respecting the therapeutical value of bibiru bark and bibirina, the reader is referred to Dr. Maclagan's papers on this subject, in the Trans. of the Royal Society of Edinburgh, vol. xv. 1843; Corinack's Lond. and Edinb. Monthly Journal of Medical Science, for August 1833; and the Edinb. Med. and Surg. Journal, No. 103. In these papers will be found the observations not only of Dr. Maclagan, but also of Drs. Rodie and Watt, of Demerara, Drs. Bonnet and Simpson of Edinburgh, and of several army medical officers serving in the East Indies.
five to twenty grains as a febrifuge. In substance, it is given in the form of pill made with conserve of roses; and in solution, with dilute sulphuric acid. The following is given as a convenient form for its exhibition as a tonic: Sub-sulphate of bibirine \( \exists \times 3 \); diluted sulphuric acid \( \exists \times n \times x v \); syrup \( \exists j \); tincture of orange-peel \( \exists j \); water \( \exists j \). Dose, one tablespoonful three times a day.

It has been recommended as an economical substitute for quinia; its price being about 6s. per oz.; while disulphate of quinia has been lately more than double that price.

**Order XXXVI. MYRISTICACEÆ, Lindley.—NUTMEGS.**

**Myristiceæ, R. Brown.**

**Characters.**—Flowers completely unisexual. Calyx tridr, rarely quadrifid; with vulvarinctation. **Males.**—Filaments either separate, or completely united in a cylinder. **Anthers** 3 to 12, 2-celled, turned outwards, and bursting longitudinally; either connate or distinct. **Females.**—Calyx deciduous. Ovary superior, sessile, with a single erect ovule; style very short; stigma somewhat lobed. Fruit coccate, delicient, 2-valved. Seed nut-like; albumen ruminate, between farty and fleshy; embryo small; cotyledons foliaicous; radicle inferior; pliinm conspicuous. **Tropical tree,** often yielding a red juice. **Leaves** alternate, without stipules, not dotted, quite entire, stalked, coriaceous; usually, when full grown, covered beneath with a close down. **Inflorescence** axillary or terminal in racemes, glomerules, or panicles; the flowers often each with one short cuplicate bract. Calyx coriaceous, mostly downy outside, with the hairs sometimes stellate, smooth in the inside (Lindley, from R. Brown, chiefly).

**Properties.**—The bark and pericarp contain an acidic juice. The seed (?) and arilloid abound in an aromatic volatile oil, which is mixed with a fixed oil.

**146. MYRISTICA FRAGRANS, Houtt.—THE TRUE NUTMEG TREE.**

**Sex. Syst. Dioica, Monadelphia.**

(Seemen putamine nodatum; oleum esminium expressum, concretum L.—Kernel of the fruit; volatile oil from the kernel; concrete expressed oil from the kernel, E.—The kernel of the fruit, D.)

**History.**—Both nutmegs and mace were unknown to the ancient Greeks and Romans; unless, indeed, the nutmeg be the aromatic Arabian fruit used in unguents, and which Theophrastus calls κακομακαφ. Pliny says that the cinnumum quid comum appellant is the expressed juice of a nut produced in Syria. Does he refer to the expressed oil of nutmeg, as some have suggested? Both mace and nutmegs are referred to by Avicenna.¹

The modern Greek names for the nutmeg and mace are respectively μοσχοκαρόμα και μοσχομάχης.

**Botany.** **Gen. Char.**—Anthers united throughout their whole length into a cylindrical column. Stigma emarginate, somewhat 2-lobed. Cotyledons folded (Blume).

**Sp. Char.**—Leaves oblong, subacute at the base, smooth. Peduncles axillary, few-flowered. Calyx urceolate. Fruit nodding, obovoid, globose, smooth (Blume). A tree from 20 to 25 feet high, similar in appearance to a pear tree. Bark dark grayish-green, smooth, with a yellowish juice. Leaves aromatic. Racemes axillary. Peduncles and pedicels glabrous, the latter with a quickly deciduous ovate bract at its summit, often pressed close to the flower. Flowers usually dioecious, sometimes monoeocious. **Males:** 3 to 5 on a peduncle; calyx fleshy, pale yellow.

¹ The juice of Dioscorides (lib. i. cap. 118, the mace of Pliny (lib. xii. cap. 18), was an astringent bark and not, as some have supposed, our mace.
² Hist. Plant. lib. ix. cap. 7. Frana (Syst. Plant. Fl. class., p. 135, 1835) considers κακομακαφ to be our nutmeg.
⁴ Lib. ii. tract. ii. cap. 436 and 503.
with a reddish pubescence. **Females:**—scarcely different from the males, except that the pedicel is frequently solitary. **Fruit** pyriform, smooth externally, about the size of a peach, marked by a longitudinal groove. **Pericarp** fleshy, dehiscent by two nearly equal longitudinal valves. **Arillode** (false aril), commonly called *Mace*, large, fleshy, branching, scarlet; when dry, yellow, brittle, and somewhat horny. **Seed** (nutmeg in the shell, office) within the arilloid, oval or ovate; its outer coat (*testa, tunica externa, or shell*) is dark brown, hard, glossy; its inner coat (*endopleura seu tunica interna*) closely invests the seed, and dips down into the substance of the albumen, giving it a marbled or ruminated appearance. The **nucleus or nut** (the round or true nutmeg of the shops) consists chiefly of the oleaginous albumen; the so-called veins of which are processes of the endopleura, which have a reddish-brown colour, and abound in oil; the **embryo** is at the base of the seed; **radicle** inferior, hemispherical; **cotyledons** 2, large, flat, foliaceous, fan-shaped; **plumule** 2-lobed.

**Hab.**—Molucca Islands, especially the group called the Banda or Nutmeg Isles. Cultivated in Java, Sumatra, Penang (Prince of Wales Island), Singapore, Bengal, Bourbon Islands, Madagascar, and some parts of the West Indies.

**Myristica pataua**, Houtt, Blume; *M. tomentosa*, Thunberg; *M. dactyloides*, Groot. (the synonyms excluded); *Nux moschata fructu oblongo*, C. Bauh; *Nux myristica man*, Clusius. A native of the Banda Isles. —Fruit elongated, ellipsoidal, rusty, tomentose. Seed elongated, ellipsoidal, covered by a membranaceous fleshy, orange coloured, insipid arilloid (mace); outer coat (*testa*) dark brown, hard; **nucleus acerbi**, slightly aromatic, grayish ash-coloured, cylindrical, ellipsoidal, rugous, marked by a furrow.—**Yields the long nutmeg** of the shops.

Colonel Sykes says, that *M. dactyloides* is frequently imposed upon the ignorant for the real nutmeg.

Closely allied to this is the **M. malabarica**, Lam., or **Malabar Nutmeg**; it is the *Panam-palca* of Rheede (Hist. Mahb. part iv. tab. 5). The latter authority says that the nucleus resembles the date in size and figure. Unlike the male or long nutmeg, it has scarcely any flavour or odour. Rheede adds, that "the Turkish and Jewish merchants mix these nutmegs with the true long ones, and the mace with good mace, selling them together. They also extract from these inferior articles an oil, with which they adulterate that of a more genuine quality." The Malabar nutmeg, according to Rheede, differs from the long nutmeg in size, hardness, and especially in flaver.

**Curing.**—In the Banda Isles there are three harvests annually; namely, the principal one in July or August, the second in November, and the third in March or April. The ripe fruit is gathered by means of a barrel attached to a long stick; the mace separated from the nut, and both separately cured. **Mace** is prepared for the market by drying it for some days in the sun. Some flatten it by the hands in single layers; others cut off the heels, and dry the mace in double blades. In rainy weather, artificial heat is employed for drying it. At first, the mace is crimson or blood-red, but after a few months acquires the golden colour preferred by the dealers. The Dutch sprinkle the mace with salt water prior to packing it in the sacks called *sokkol*.

---

1 The succinate envelope of the nutmeg, usually called the aril, and which constitutes the substance called *mace*, is said by M. Pinchon to be nothing but an expansion of the exostome, and, therefore, an *arilloide* or false aril.

2 The Dutch endeavoured to confine the growth of the nutmeg to three of the Banda Isles; viz., Lantoir or Banda proper, Banda-Neira, and Way (Palo Ay); but their attempts were partly frustrated by a pigeon, called the *nuxmeia bird* or *nut-eater* (a species of *Coracippogla*), which, extracting the nutmeg from its puhly pericarp, digests the mace, but voids the nutmeg in its shell, which, falling in a suitable situation, readily germinates. Young plants thus obtained are used for transplanting into the nutmeg *parks*. During the time that the English had possession of the Molucca Islands, namely, from 1790 to 1802; and, again, from 1810 to 1814, they exported plants to Bencoolen in Sumatra, to Penang, India, and other places. In 1819, the nutmeg tree was sent from Bencoolen to Sumatra, where it is now largely cultivated. (For a sketch of the culture and trade in nutmeg, and of the monopolizing policy of the Dutch, the reader is referred to *Hooker's Bot. Mag.* vol. i. N. S. i. 1827, t. 2570 to 2577; also Stephenson and Churchill's *Med. Bot.* vol. iii. pl. 184.)

Nutmegs:—Description and Varieties.

Nutmegs require more care in curing, on account of their liability to the attacks of an insect (the nutmeg insect). It is necessary to have them well and carefully dried in their shells, as in this state they are secure from the attack of this insect.\(^1\) In order to effect this they are placed on hurdles or gratings, and smoke-dried for about two months by a slow wood-fire, at a heat not exceeding 140°F. (In the Banda Isles they are first sun-dried for a few days.) When thoroughly dried, the nuts rattle in the shells, which are then cracked with wooden mallets, and the worm-eaten and shrivelled nuts thrown out.

To prevent the attacks of the insect the nuts are frequently limed. For the English market, however, the brown or unlined nutmegs are preferred. The Dutch lime them by dipping them in a thick mixture of lime and water; but this process is considered to injure their flavour. Others lime them by rubbing them with recently prepared, well-sifted lime. This process is sometimes practised in London.

After being garbled, the nutmegs are packed for transportation in tight casks, the insides of which have been smoked and covered with a coating of fresh water and lime. Newbold says the unlimed nutmegs are mixed with cloves.

The dried produce of a nutmeg tree consists of nutmeg, mace, and shell, in the following proportions: In 15 parts of the whole produce there are 2 parts of mace, 5 of shell, and 8 of nutmegs. Hence, although nutmegs in the shell may keep better than the clean or shelled nutmegs, yet the heavy allowance required for the shell (viz. about one-third) is a serious objection to their preservation in this form.

Description. 1. Of Nutmegs (Nucis moschatæ).—In commerce, two kinds of nutmegs are met with; one called the true or round, the other the long or wild.

a. True or Round Nutmeg; the female nutmeg; nux myristica femina, Clusius; nux moschata fructu rotundo, C. Bauh.—This sort is the produce of Myristica fragrans. It is about an inch in length. Its shape is roundish or elliptical, like that of the French olive. Externally, it is marked with reticulat furrows. The colour of the unlimed or brown nutmegs is ashy brown; that of limed nutmegs is brown on the projecting parts, and white (from the presence of lime) in the depressions. Internally, nutmegs are pale reddish-gray, with red veins. The odour is strong, but pleasant, peculiar, and aromatic. The taste is agreeable and aromatic.

Occasionally, the round nutmeg is imported in the shell. This is dark and shiny.

A very small nutmeg, not larger than a pea, has been described under the name of the royal nutmeg (nux moschata regia).

In the London Market, the following are the sorts of round nutmegs distinguished by the dealers:

1. Penang nutmegs.—These are unlimed or brown nutmegs, and fetch the highest price. They are sometimes limed here for exportation, as on the continent the limed sort is preferred. According to Newbold, the average amount annually raised at Penang is 400 piculs (of 133\(^\frac{1}{3}\) lbs. each).

2. Dutch or Batavian nutmegs.—These are limed nutmegs. In London, they scarcely fetch so high a price as the Penang sort.

3.—Singapore nutmegs.—These are a rougher, unlimed, narrow sort, of somewhat less value than the Dutch kind. According to Mr. Oxley, 4,085,361 nutmegs were produced at Singapore, in 1848, or about 252 piculs (of 133\(^\frac{1}{3}\) lbs. each); but the greater number of the trees had not come into full bearing, and it was estimated that the amount would, in 1849, be 300 piculs.

\(1\) Crawford, Hist. of the Ind. Archip.
3. Long or Wild Nutmegs;\(^3\) the male nutmeg; \textit{nux myristica mae}, Clusius; \textit{nux moschata fructu oblongo}, C. Bauhin.—

This is the produce of Myristica fatua. It is met with in commerce in three forms: in the shelled or clean state (long or wild nutmegs), contained within the shell (long or wild nutmegs in the shell), and with mace dried around them (long or wild nutmegs covered with mace).

The long or wild nutmeg in the shell in shape is oblong, like that of the date; its length about an inch and a half. The shell is bony, somewhat brittle, externally shiny and brown, internally dull, grayish-white. The contained seed is paler coloured and less aromatic than in the preceding sort. Some specimens are almost insipid. Are these the Malabar wild nutmegs before referred to (see ante, p. 412)? The mace which is sometimes found in the long nutmeg is insipid.

2. Of Mace (\textit{Macis}).—Two kinds of mace are found in commerce; one called true or genuine, the other wild or false.

a. True or genuine mace.—This is the produce of the round or true nutmeg. It occurs in single or double blades, flat, irregularly slit, smooth, slightly flexible or brittle membrane, of a pale cinnamon-yellow or golden-yellow colour, and an odour and taste analogous to those of nutmegs. Although the natural colour of mace is red, yet red-coloured mace is looked on suspiciously.

The London dealers distinguish three sorts of genuine mace;—

1. Penang mace.—This fetches the highest price. It is flaky and spread. The annual quantity produced in Penang is about 130 piculas (of 133½ lbs. each).

2. Dutch or Batavian mace.—This is a fleshy sort; it scarcely fetches so high a price as the Penang sort.

3. Singapore mace.—This is a somewhat inferior kind.

3. Wild or false mace.—This is a dark red mace, the produce of the long or wild nutmeg, and is also devoid of aromatic flavour.

COMPOSITION.—Nutmegs were analyzed in 1823 by Bonastre.\(^3\) In 1824, an analysis of mace was made by N. E. Henry.\(^3\)

Mace.

The volatile oils and the fats will be noticed hereafter, as they are employed in medicine. The starch occurs in small compound grains.

CHEMICAL CHARACTERISTICS.—The presence of starch in both nutmegs and mace may be detected by a solution of iodine, which gives them a blue tint (iodide of starch). Both of these substances yield, by distillation with water, a volatile oil, characterized by its peculiar odour; and both yield, by expression, a fixed butyricous oil.

PHYSIOLOGICAL EFFECTS.—The activity of both nutmegs and mace depends on the volatile oil which they contain. Swallowed in moderate quantities, they produce the before-described effects of the spices (see vol. i. p. 250). In large doses

\(^3\) Sir J. E. Smith (Rees’s \textit{Cyclopædia}) says that in 1797 they were received from Banda under the name of \textit{New Guinea nutmegs}. A specimen of the fruit and leaves, preserved in spirit in the Banksian collection, is marked the long nutmeg from Sumatra.

\(^3\) Journ. de Pharm. t. ix. p. 281, 1823.

\(^3\) Ibid. t. x. p. 281, 1824.
they prove narcotic, and cause giddiness, delirium, precordial anxiety, sleepiness, or actual stupor. Instances of this kind are mentioned by Bontius,1 Rumphius,2 Lobel,3 Schmid,4 and Cullen.5 In the case related by the last-mentioned authority, two drachms of powdered nutmegs produced drowsiness, which gradually increased to complete stupor and insensibility. The patient continued for several hours alternately delirious and sleeping, but ultimately recovered. Purkinje6 has confirmed these statements by experiments made on himself. I am acquainted with a case in which the narcotic effects of a whole nutmeg have been several times experienced.

Uses.—The principal consumption of nutmegs and mace is for dietetical purposes. They serve to flavour, and, by their stimulant properties, to assist the digestive process. Food highly seasoned with substances may prove these injurious in cerebral affections (apoplexy, for example), on account of their narcotic properties. Medicinally they are used, like other spices, as stimulants, carminatives, and flavouring ingredients. Nutmeg is an important constituent in the confection aromaticae (see p. 383) so frequently employed as a cordial and antacid in bowel complaints. In mild cases of diarrhoea, I frequently employ nutmeg as a substitute for opium. It may be taken in warm brandy and water, unless the use of spirit be contraindicated.

Administration.—Either nutmeg or mace may be taken to the extent of a scruple or half a drachm, in powder obtained by grating; or the volatile oil of these substances may be used in doses of 3 min. to 4 min.

1. Oleum Myristici, E. D. [U. S.]; Oleum Nucis Moschatae; Oleum Nucis aetheræ; Essential Oil of Nutmeg; Volatile Oil of Nutmeg.—(Pro- curred by submitting Nutmegs and Water to distillation.)—The usual produce of volatile oil in the distillations at Apothecaries' Hall, London, is 4.5 per cent.; but the oil is generally imported. It is colourless, or pale yellow, has the odour and taste of nutmegs, and a viscid consistence. By agitation with water it separates into two oils, one lighter, the other heavier than water. By keeping, it deposits crystals of stéaroptène (myristicine), which are fusible at 212° F., volatile, soluble in alcohol, in ether, and in boiling water; from the latter liquid myristicine separates in a crystalline form as the liquid cools. According to Mulder, the stéaroptène consists of C₁₀H₁₆O₁. Volatile oil of nutmegs is seldom employed medicinally. Its dose is 3 min. to 4 min., taken on sugar, or dissolved in spirit.

2. Oleum Macidis; Essential Oil of Mace.—This is colourless or pale yellow, lighter than water, and has the flavour and odour of mace. Its composition, effects, and uses are similar to those of nutmegs.

3. Myristica Adeptis, E.; Myristice Oleum, L.; Oleum vel Balsamum Nucisæ; Butter of Nutmegs; Expressed or Concrete Oil of Nutmegs.—In the shops, it is usually denominated expressed oil of mace. It is prepared by beating the nutmegs to a paste (which is to be inclosed in a bag, and then exposed to the vapour of water), and afterwards exposing by heated plates. It is imported in oblong cakes (covered by some monocotyledonous leaves, commonly called flag leaves), which have the shape of common bricks, but whose size is somewhat smaller. Its colour is orange, its consistence firm, its odour fragrant, like that of the seeds from which it is obtained. In 1804, it was examined by Schrader,7 who found that 16 parts of concrete oil, expressed by himself, consisted of 1 part of volatile oil, 6 parts of brownish-yellow fat, and 9 parts of white fat. In 16 parts of the commercial concrete oil, he found 4 3/4 volatile oil, 8 4/8 yellow fat, and 7 parts of white fat. The volatile oil and yellow fat are soluble in both cold alcohol and cold ether. The white fat (known by the name of corpus pro balsamis, or mater balsamorum), is

6 Jbid.
7 Jbid.
soluble in boiling alcohol and boiling ether; but is insoluble in cold alcohol and ether. It has been more recently examined by Dr. L. Playfair, who calls it myristine (formerly servicine). By saponification it yields glycerine and myristic acid \( (\text{C}_{16}^n \text{H}_{30}^o, 110) \). Playfair mentions a false butter of nutmegs, composed of animal fat, boiled with powdered nutmegs, and flavoured with sassafras. The specimen may be relied on as pure, if it dissolve in four times its weight of strong boiling alcohol, or half that quantity of ether.

Expressed oil of nutmegs is occasionally employed externally in chronic rheumatism and palsy. It is a constituent of Empilastra Picis (see ante, p. 302).

4. SPIRITUS MYRISTICÆ, L. E. [U. S.]; Spirit of Nutmeg.—(Nutmegs, bruised, \( 5^j \mathrm{js} \) or \( 5^i \mathrm{j}. \mathrm{U.} \mathrm{S}.) \); Proof Spirit [Diluted Alcohol, U. S.], Cong. j.; Water Oj. Mix them, then [with a slow fire, L.] let a gallon distil.)—It is frequently prepared by mixing volatile oil of nutmegs with proof spirit. It is cordial and carminative; and is employed in doses of \( f^j \) to \( f^jiv \), as a pleasant addition to stimulant, narcotic, or purgative draughts.

5. ESSENTIA MYRISTICÆ MOSCHATAE, D.; Essence of Nutmeg.—(Volatile Oil of Nutmegs \( f^j \); Stronger Spirit \( f^jix \). Mix with agitation, \( D. \))—Used as a substitute for the Spirit of Nutmeg. Dose, a few drops on a lump of sugar.

ORDER XXXVII. THYMELACEÆ, Lindl.—DAPHNADS.

Thymeæ, Jussieu.—Daphnoideæ, Endl.

Characters.—Calyx inferior, tubular, coloured; the limb 4 cleft, seldom 5-cleft, with an imbricated adnation. Corolla 0, or sometimes, scale-like petals in the orifice of the calyx. Stamens definite, inserted in the tube or its orifice; often 8, sometimes 4, less frequently, 2; when equal in number to the segments of the calyx, or fewer, opposite to them; anthers 2-celled, dehiscing lengthwise in the middle. Ovary composed of a single carpel, with 1 solitary pendulous anatropous ovule; style 1; stigma undivided. Fruit hard, dry, and nut-like, or drupaceous. Albumen 0, or thin and fleshy; embryo straight; cotyledons plano-convex, sometimes lobed and crumpled; radicle short, superior; plumule inconspicuous.—Stem shrubby, very seldom herbaceous, with tenacious bark. Leaves without stipules, alternate or opposite, entire. Flowers capitulate or spicate, terminal or axillary, occasionally solitary, sometimes unisexual by abortion, often inclosed in an involucre (R. Brown, with some additions).

Properties.—The prevailing property of the plants of this order is acridity. This depends on a principle contained in the bark and pericarp. The liber of many species is remarkably tough, and is applied to various useful purposes; as for making ropes, whips, a kind of cloth, &c. —The Lagetta linaria or the Lace Bark Tree, which possesses the medicinal properties of mezereon, and has been used in the same cases, is provided with a bark, which may be separated into 20, 30, or more laminae, which are fine and white like gauze; and of these, caps, ruffles, and even whole suits of ladies’ clothes, have been made. Some few years since, a quantity of the stiffened lagetta cloth was imported into Liverpool under the name of guana.

147. DAPHNE MEZEREUM, Linn.—COMMON MEZEREON OR SPURGE-OLIVE.

Scc. Syst. Octandria, Monogynia.

(Radicis cortex, L.—Root-bark, E. D.)

History.—Tragus\(^1\) is the earliest author who mentions this plant.\(^2\) He calls it Thymelæa. The Mezereum of Avicenna,\(^3\) and of other Arabian authors, is declared by C. Bauhin to be Chamelæa tricocca (now called Cneorum tricoccon), a plant of the order Euphorbiaceæ; but it is probably identical with the zaraiku of Dioscoreides, which is declared by Sibthorpe\(^4\) and Fraas\(^5\) to be Daphne oleoides.

BOTANY. Gen. Char.—*Flowers* hermaphrodite. *Calyx* funnel-shaped; limb in 4 segments; throat without scales. *Stamina* 8, inclosed within the tube, inserted in 2 rows near the throat. Hypogynous scales 0. *Ovary* 1-celled. *Style* terminal, very short; *stigma* capitate. *Drupe* baccate, 1-seeded, naked, with a crustaceous putamen or stone. *Seed* inverted; *albumen* 0; *embryo* orthotropic; *cotyledons* plano-convex (*Endlicher*).

Sp. Char.—*Flowers* naked on the stem, sessile, about 3 together. *Leaves* lanceolate, deciduous (*Smith*).

Stem bushy, 4 or 5 feet high, with upright, alternate, smooth, tough, and pliant branches; leafy while young. *Leaves* scattered, stalked, lanceolate, smooth, 2 inches long, appearing after the flowers, and soon accompanied by flowe-buds for the next season. *Flowers* highly, and to many persons too powerfully, fragrant, seated in little tufts on the naked branches, with several brown, smooth, ovate bracteas underneath. *Calyx* like a corolla in texture, crimson all over; the tube, externally hairy. *Berries* scarlet.

Var. *flore albo* has white flowers and yellow fruit.

Var. *autumnale* has larger leaves and flowers in the autumn.

Description of the Bark.—The root-bark (*cortex radicis mezerei*) is alone employed in this country. It is tough, pliable, and when dry fibrous; externally brown and corrugated; internally white, tough, and cottony. It occurs in strips of several inches long. When chewed, the taste is at first sweetish; afterwards an acrid burning sensation is felt in the mouth and fauces, and extends to the gullet and stomach if the bark and saliva be swallowed. This sensation continues for several hours. The odour of the fresh root is faint, but marked.

The stem-bark (*cortex caulcis vel caulis mezerei*) is usually considered to be somewhat less active than the root-bark; but in the Dublin, United States, and most of the continental Pharmacopœias, the bark of both root and stem is included under the general name of *mezereon bark* (*cortex mezerei*). The stem-bark, in the fresh state, is externally somewhat darker and rougher than the root-bark; but it is most readily recognized, in the fresh state, by the green colour of the cellular integument beneath the epidermis.

In Germany, the bark of the stem and larger branches is removed in spring, folded in small bundles, and dried for medicinal use. It is imported from Hamburg.

I am informed by Mr. M'Culloch, of Covent Garden Market, that the root-bark commands nearly three times the price of the stem-bark. The bark is stripped from the crushed roots while fresh and soft.

Sometimes the entire root (bark and wood) of mezereum is used instead of the root-bark; but this proceeding is highly objectionable, as the wood possesses only a feebie acidity.

The bark of other species of *Daphne* (as of *D. Gnidium* and *D. Laureola*) is said to be sometimes substituted for that of the mezereon.

Mr. Squire\(^1\) states that

\[ 13\frac{1}{2} \text{ lbs. of fresh mezereon} \times 3\frac{1}{2} \text{ lbs. of wood.} \]

root produced by drying \( 3\frac{1}{2} \text{ lbs. of bark, dry} \); equivalent to \( 8\frac{1}{4} \text{ lbs. of fresh bark.} \)

3 lbs. of stems produced \( 3\frac{1}{4} \text{ lb. of dried bark.} \)

Composition.—The bark of the stem was analyzed by C. G. Gmelin and Bär,\(^2\) and found to consist of *wax*, *an acid resin, dophmin*, a trace of volatile oil, *yellow colouring principle, uncrystallizable but fermentable sugar, nitrogenous gummy matter, reddish brown extractive, woody fibre, free malic acid, and malates of potash, lime, and magnesia.*

\(^1\) *Pharmaceutical Journal*, vol. i. p 395, 1842.  
1. Acrid Resin.—Obtained by boiling the bark in alcohol; when the solution cools, some wax is deposited. The supernatant liquid is to be evaporated, and the residual extract washed with water. The resin then left behind is dark green, and soluble in both alcohol and ether. To this substance mezereon owes its acridity. There is, however, some reason to suspect that this resin is itself a compound of two principles, viz. an acid, vesicating, fixed oil, and another substance. The resin is rendered soluble in water by means of the other constituents of the bark. Mr. Squire could not obtain any blistering effect from the resin extracted by alcohol.

2. Daphne.—A peculiar crystalline principle, having a bitter, slightly astringent taste. It is soluble in alcohol and ether, but possesses neither basic nor acid properties. Gmelin and Bar consider it to be analogenous to asparagin. It is not the active principle of mezereon.

3. Acrid Volatile Oil.—According to Mr. Squire, mezereon contains a volatile acid substance which is carried off by the vapour of water, but not by the vapour of alcohol. He says that "the pungent odour given off by boiling mezereon root in water over a lamp is so powerful, that, after holding my head over it for a short time, great irritation was produced, and it was difficult to carry on respiration."

Physiological Effects.—All parts of the plant, but more especially the bark and the fruit, are endowed with excessive acridity; in virtue of which they cause irritation and inflammation in tissues to which they are applied. When swallowed, therefore, in large quantities, they prove poisonous. The topical action of mezereon bark is that of an irritant, and, when the bark has been applied to the skin, vesicant.

A decoction of mezereon bark, taken in moderate quantities, sometimes appears to promote the action of the secreting and exhaling organs (especially the kidneys and the skin). But Dr. Alex. Russell could not observe, upon the strictest inquiry, "that it sensibly increases any of the secretions, more than the same quantity of any small liquor would do." In some cases it proves laxative, where the patients are easily moved, and large doses disturb and irritate the stomach. Richter says that, under the long-continued use of mezereon, the saliva acquires a peculiar odour. In larger doses it causes dryness and heat in the throat, increased saliva, pain in the stomach and bowels, and sometimes vomiting and purging—the stools being occasionally bloody. The urinary organs are sometimes specifically affected by it; irritation, analogous to that produced by cantharides, being set up by it. An affection of the cerebro-spinal system (marked by great feebleness, giddiness, incapability of keeping the erect posture, and slight convulsive movements) is occasionally brought on. I am unacquainted with any cases which have proved fatal from the use of mezereon bark. Vicat mentions the case of a dropical patient, in whom the wood caused diarrhoea, pain, and vomiting, which continued for six weeks.

Uses.—In this country, mezereon is scarcely ever employed alone. It is usually administered in conjunction with sarsaparilla (see ante, p. 275), and is employed as a sudorific and alterative in venereal, rheumatic, scrofulous, and chronic cutaneous diseases. Decoction of the root-bark of mezereon was recommended to the notice of the profession, by Dr. Alexander Russell, as a very efficacious remedy in cases of venereal nodes and nocturnal pains. Dr. Home also speaks of it as "a powerful deobstruent in all venereal tumours of the scirrhous kind, where mercury has failed." But Mr. Pearson, after many years' observation of it, says, "I feel myself authorized to assert unequivocally, that the mezereon has not the power of curing the venereal disease in any one stage, or in any one form." Dr. Cullen employed it with success in some cutaneous diseases.

As a topical remedy, it is sometimes applied to relieve toothache. It is occasionally used as a masticatory. Dr. Withering cured a case of difficulty of swallowing (arising from a paralytic affection) by mezereon, which he directed to be chewed frequently. In France, the bark of both Daphne mezereum and D. Guilielmi is used as a vesicatory. The mode of applying it is this: First soften the

9 Vogt, Pharmakognosik, Bd. ii. S. 305, 2te Aufl. 6 Orglin, Toxicol. Gen.
10 Observ. on the Effects of Various Articles of the Nat. Med. 1890.
bark by soaking it in hot vinegar and water, and then apply it to the part by a compress and bandage. The application is to be renewed night and morning, until vesication is produced.

Administra tion.—Mezereon is usually administered internally, in the form of decoction. It is a constituent of the decoctum sarcae compositum (see ante, p. 278). As a masticatory, a few grains of the bark may be chewed.

For external use, an ointment prepared with the extract is sometimes employed.

Antidote.—In a case of poisoning by mezereon, evacuate the contents of the stomach as speedily as possible, and give emollient drinks, opiates, and the vegetable acids. To counteract inflammatory symptoms, the usual antiphlogistic treatment should be adopted.

1. DECOCTUM MEZEREI, E.; Decoction of Mezereon.—(Mezereon Bark, in chips, $\frac{3}{ij}$; Liquorice Root, bruised, $\frac{5}{as}$; Water Oij. Mix them, and boil down with a gentle heat to a pint and a half, and strain.)—Stimulant and sudorific. Used in chronic rheumatism, and secondary syphilis. Dose, $\frac{f}{x}iv$ to $\frac{f}{vii}$ three, or four times a day.

From Mr. Squire’s observations, already referred to, it appears that ebullition is injurious to the action of mezereon, by dissipating a volatile active principle.

2. EXTRACTUM MEZEREI ALCOHOLICUM; Alcoholic or Spiritual Extract of Mezereon.—A tincture of mezereon is first made with rectified spirit, and the spirit then drawn off by distillation.

In the Prussian Pharmacopoeia, the alcoholic extract is directed to be digested in ether, and from the ethereal tincture is obtained by distillation the extractum mezerei etherum.

Extract of mezereon is greenish or brownish-green coloured, and is insoluble in water. Mr. Squire obtained a draehm of dry resin (alcoholic extract) by digesting half an ounce of the bruised bark in ten ounces of alcohol, and then distilling off the alcohol. During the distillation, none of the pungency of the root came over.

Extract of mezereon is used for the preparation of a blistering ointment or tissue.

3. UNGUENTUM MEZEREI [U. S.]; Mezereon Ointment.—The Prussian Pharmacopoeia directs this to be prepared by mixing $\frac{3}{ij}$ of the ethereal extract of mezereon with $\frac{3}{ij}$ of wax ointment. In the Hamburgh Codex, it is prepared by dissolving $\frac{3}{ij}$ of the spirituous extract in a small quantity of spirit, and then mixing $\frac{3}{vii}$ of purified lard and $\frac{3}{ij}$ of white wax.—(The U. S. Pharm. directs to take of Mezereon, sliced transversely, four ounces; Lard fourteen ounces; White Wax two ounces. Moisten the mezereon with a little alcohol, and beat it in an iron mortar until reduced to a fibrous mass; then digest it, by means of a salt-water bath, with the lard and wax previously melted together, for twelve hours; strain with strong expression, and allow the strained liquid to cool slowly, so that any undisolved matters may subside. From these separate the medicated ointment.)—The ointment is used as an irritant. Applied to ulcers or wounds, it serves to excite suppuration. Mr. Squire states that an ointment made by boiling the root in lard soon spoils by keeping.

(Cortex.)

Laureola, Gerard; Parkinson, 205.—This is another indigenous species of Daphne. It has drooping axillary racemes of green flowers, evergreen lanceolate leaves, and black berries. Mr. Squire says that 7 lbs. of the root yielded 4 lbs. 5 oz. of fresh bark, or 1 lb. 14 oz. of dry bark; and 11 pounds of the stems yielded 12 lbs. of fresh bark, which, when dried, weighed 2 lb. The liver is remarkably tough. In colour, and irritating effect on the throat, the bark of the spurge-laurel appeared to him to be weaker than that of mezereon. Half an ounce of the bruised bark yielded him 45 grs. of alcoholic extract. In its effects, spurge-laurel resembles mezereon. Parkinson mentions its emmenagogue properties. Some years ago, a farmer gave a girl, aged 17, three pills to procure abortion. They caused violent vomiting, convulsions (dur-
ing which she aborted), coma, and paralysis, from which she slowly recovered. A microscopic examination of the fragments of leaves in the pills led the late Mr. Edwin Quackett to believe that the poison was this plant.

149. Daphne Gnidium, \textit{Linn.}—The Flax-leaved Daphne.

(\textit{Cortex.})

\textit{Gnidium}, Dioscorides, lib. iv. cap. 173. The berries were the \textit{xines gnidia}, \textit{grana gnidia} or \textit{gnidian berries} used by Hippocrates.\textsuperscript{1} The properties of this species of Daphne resemble those of Menereon. In France, the bark (called garou) is used in the way before described (see \textit{Daphne Mezerum}) as a vesicatory.

\textbf{ORDER XXXVIII. POLYGONACEAE, \textit{Lindl.}—Buck-wheats.}

\textbf{Polygonae, Justicia.}

\textbf{Characters.}—\textit{Calyx} free, often coloured, imbricated in \textit{ aestivation. Stamens} very rarely perigynous, usually definite and inserted in the bottom of the \textit{calyx}; \textit{anthers} dehiscing lengthwise. \textit{Ovary} free, usually formed by the adhesion of 3 carpels, 1-celled, with a single erect ovule, whose foramen points upwards; \textit{styles} and \textit{stigmas} as many as the carpels. \textit{Ovules} other tropal. \textit{Nut} usually triangular, naked, or protected by the \textit{calyx}. \textit{Seed} with farinaceous albumen, rarely with scarcely any; \textit{embryo} inverted, generally on one side, sometimes in the axis; \textit{radicle} superior, long.—\textit{Herbaceous} plants, rarely \textit{shrubs. Leaves} alternate, their stipules cohering round the stem in the form of an \textit{ochrea} (or boot); when young rolled backwards, occasionally wanting. \textit{Flowers} occasionally \textit{unisexual}, often in racemes (\textit{Lindley}).

\textbf{Properties.}—The herbaceous plants are distinguished by their acidulous character. They owe this to the presence of vegetable acids, chiefly oxalic acid. This is found in the form of a superoxalate of potash (or soda), which communicates to the leaves and petals refreshing and refrigerant qualities. The roots contain colouring and astringent matter, and often oxalate of lime. Some of them are purgative. The seeds of some species serve as a kind of corn for cattle, and, in times of scarcity, for man.

150. \textbf{RHEUM}.—\textbf{RHUBARB.}

\textit{Sec. Syg.} Enneandria, Monogynia.

(Rheum Sinense; \textit{Rhei}, \textit{species incerta}; \textit{Radix, L.} The root of undetermined species.—\textit{E. D.})

\textbf{History.}—Dioscorides\textsuperscript{3} speaks of a root which he calls \textit{rha} or \textit{rheon (\textit{p\textsuperscript{a} r\textsuperscript{h}e\textsuperscript{n}o\textsuperscript{n}})}, and which has been regarded by some as identical with our rhubarb. \textit{"Rha, by some called rheon, grows," says Dioscorides, \textit{"in those countries which are beyond the Bosphorus, and from which it is brought. It is a root which is black externally, like to great century, but smaller and redder, odourless, loose or spongy, and somewhat smooth internally."} Pliny\textsuperscript{3} gives a similar account of it, under the name of \textit{rhacoma}; it comes, he says, from the countries beyond Pontus, resembles the black costus, is odourless, and has a hot, astringent taste. Prosper Alpinus\textsuperscript{4} was of opinion that the \textit{rha} of Dioscorides was the root of Rheum rhaponticum, which Alpinus obtained from Thracia, in 1608, A.D., and cultivated at Pavia. The later Greek writers are supposed to have been acquainted with our rhubarb. Alexander of Tralles\textsuperscript{5} is the first who speaks of it. He used it in weakness of the liver and dysentery. Paulus \textit{Ægineta} says that, in the crudities and vomiting of pregnant women, we may give \textit{"the knot-grass, boiled in water, for drink; and likewise dill, and the pontic root, called rha in the dialect of its native country;"} and, in noticing the practice of the ancients, he says, \textit{"alvina discharges they promoted by giving turpentine to the extent of an olive, when going to rest; or, when they wished to...}
purge more effectually, by adding a little rhubarb;" [rheon.] This is the first notice of the purgative properties of rhubarb.

In one of the Arabian authors (Mesue, the younger) we find three kinds of rhubarb mentioned: The Indian, said to be the best; the Barbarian; and the Turkish, which is the worst of all.

BOTANY. Gen. Char.—Calyx petaloid, 6-parted, withering. Stamina about 9, inserted into the base of the calyx. Styles 3, reflexed. Stigmas peltate, entire. Acheneum 3-cornered, winged, with the withered calyx at the base. Embryo in the centre of the albumen (Lindley).

It is not yet ascertained what species of Rheum yields the official rhubarb. Several species, now cultivated in this country, have been, at different times, declared to be partially or wholly the source of it. Formerly, Rheum Rhaponticum was supposed to yield it.3

In 1732, R. undulatum was sent from Russia to the Messrs. Jussieu at Paris, and to Rand of Chelsen, as the true rhubarb. This is the species which Linnaeus described as R. Rhubarbarum.4 About 1750, at the desire of Kauw Boerhaave, first physician to the Emperor of Russia, the senate commissioned a Tartarian merchant, a dealer in rhubarb, to procure them some seeds of the genuine plant. This he did, or pretended to do; and, on sowing them, two species of Rheum were obtained; namely, the undulatum and the palmatum.5 In 1762, seeds of the latter species were received by Dr. Hope, of Edinburgh, from Dr. Mounsey, at Petersburg; they were sown, and the plants cultivated with success.6 The root of this species being found to agree, in many of its characters, with that of genuine rhubarb, led to the belief that the palmatum was the true species. The inquiries of Pallas, however, raised some doubts about the correctness of this opinion; for the Bucharians declared themselves unacquainted with the leaves of the palmatum, and described the true plant as having round leaves, with a few incisions only at the margin. This description agreed best with Rheum compactum, the roots of which were declared, by Millar, who cultivated the plant, to be as good as foreign rhubarb.7 Georgi says, that a Cossack pointed out to him the leaves of the R. undulatum as the true species.7 These accounts were not satisfactory to the Russians; and, in consequence, in 1790, Sievers, an apothecary, went to Siberia, under the auspices of Catherine II, with a view of settling the question; but, after four years of persevering attempts to reach the country where the true rhubarb grew, or even to obtain the seeds, he was obliged to be satisfied with negative results only. "My travels," says he, "as well as acquaintance with the Bucharians, have satisfied me that as yet nobody—that is, no scientific person—has seen the true rhubarb plant. All that is said of it by the Jesuits is miserable, confused stuff; all the seeds procured under the name of true rhubarb are false; all the plantations, from those of the Knight Murray down to the flower-pot of a private individual, will never yield true rhubarb. Until further determination, I hereby declare all the descriptions in all the Materia Medicas to be incorrect."8 Calau,9 Apothecary in the Rhubarb Factory at Kachuta, and who, from his appointment, might be expected to know the origin of the rhubarb he receives from the Bucharians, says, "All that we know of the rhubarb plant or its origin is defective and wrong; every sacrifice to obtain a true plant or the seed has been in vain; nor has the author been enabled to obtain it. A severe prohibition from the Chinese government prevents all possibility of eliciting the truth."

Himalayan rhubarb is obtained from several species of Rheum: viz. R. Emodi, Wallich,10 R. Webbianum, Royle;11 R. spiriforme, Royle; and R. Moorcroftianum, Royle; but there are no reasons for supposing that they yield any of the rhubarb of European commerce. It is not improbable that the species yielding the official rhubarb is yet undescribed. Dr. Royle,"12 after referring to the accounts of different authors, as to the precise locality of the country yielding Russian rhubarb, concludes that it is within 25° of E. long. in 35° of N. latitude—that is, in the heart of Thibet. And he adds, "as no naturalist has visited this part, and neither seeds nor plants have been obtained thence, it is as yet unknown what species yields this rhubarb."

The late Mr. Anderson, of the Apothecaries' Botanic Garden, Chelsen, furnished me with the fresh roots of thirteen species of Rheum: viz. R. palmarum, undulatum, compactum, Rhaponticum, Emodi, cassinervorum, capsicum, tartaricum, hybricum, confusum, Fischeri, bardanifolium, and bullatum. Having carefully dried these by artificial heat, I found that one species only, viz. R. palmarum, closely resembled Asiatic rhubarb in the combined qualities of odour, colour, and marbling: R. undulatum agreed tolerably well in colour and marbling, but not in odour. It deserves, however, to be noticed that the specimens examined were of unequal ages—some forming the rootstock, others root-branches of the respective plants—a circumstance which considerably diminishes the value of a comparative examination of them. Furthermore, all the samples were

8 Ibid. p. 999.
probably injured by the wet season. The root-branches of *R. crassinerum* (from a strong plant of six or seven years old, but which had not flowered) did not resemble Asiatic rhubarb in either colour or odour.

**Species**—I. *With compound racemes.*

1. **Rheum palmatum**, Linn. L.D. *Palmated Rhubarb.* Commonly known to gardeners as the True Turkey Rhubarb.—"Leaves roundish-cordate, half palmate; the lobes pinnatifid, acuminate, deep dull green, not wavy, but uneven, and very much wrinkled on the upper side, hardly sebaceous at the edge, minutely downy on the under side; sinus completely closed; the lobes of the leaf standing forward beyond it. Petiole pale green, marked with short purple lines, terete, obscurely channelled quite at the upper end. Flowering stems taller than those of any other species," (Lindley.)—Perennial. Grows spontaneously in the Mongolian empire, on the confines of China. Its leaf-stalks make excellent tarts and puddings.

Prof. Guibourt* observes that out of the roots of *R. palmatum, undulatum, compactum,* and *Rhaponticum,* those of the first species possess only the exact odour and taste (grittiness excepted) of the China rhubarb.

2. **Rheum undulatum**, Linn. D. *Wave-leaved Rhubarb.—"Leaves oval, obtuse, extremely wavy, deep green, with veins purple at the base, often shorter than the petiole, distinctly and copiously downy on each side, looking as if frosted when young, sebaceous at the edge; sinus open; wedge-shaped, with the lower lobes of the leaves turned upwards. Petiole downy, bloody, semicylindrical, with elevated edges to the upper side, which is narrower at the upper than the lower end," (Lindley.)—Perennial. Grows in Siberia (Georgi and Pallas, cited by Murray), and China (Ammann, quoted by Lindley). Cultivated in France, and yields part of the French Rhubarb. It was formerly cultivated at Siberia as the real official plant; but, as genuine rhubarb could not be procured from it, its cultivation has been given up.

3. **Rheum compactum**, Linn.; *Thick-leaved Rhubarb.—"Leaves heart-shaped, obtuse, very wavy, deep green, of a thick texture, sebaceous at the margin, quite smooth on both sides, glossy and even on the upper side; sinus nearly closed by the parenchyma. Petiole green, hardly tinged with red, except at the base, semicylindrical, a little compressed at the sides, with the upper side broad, flat, bordered by elevated edges, and of equal breadth at each end," (Lindley.)—Perennial.

* In 1834, Geiger (*Pharm. Central Blatt füür 1834, S. 969*) made a comparative examination of the roots of *R. Emodi, compactum, undulatum, and Rhaponticum.*
* Hist. Des. Drugs.*
Rhubarb:—Species; Preparation.

Grows in Tartary and China. Cultivated in France, and yields part of the French rhubarb.\(^1\) This rhubarb is a very fair imitation of that from China; but is distinguished by its reddish tint, its different odour (common to it, to \textit{R. undulatum}, and \textit{R. rhaponticum}), its close and radiated marbling, its not tinging the saliva, and its not grating under the teeth.

4. \textit{Rheum Emodi}, Wallich; \textit{R. austrole}, Don.—\(^{11}\) Leaves cordate, acute, dull green, but little wavy, flattish, very much wrinkled, distinctly rough, with coarse short hairs on each side; sinus of the base distinctly open, not wedge-shaped, but diverging at an obtuse angle, with the lobes nearly turned upwards. Petioles very rough, rounded angular, furrowed; with the upper side depressed, bordered by an elevated edge, and very much narrower at the upper than the lower end.\(^2\) (Lindley.)—Perennial. Grows on the Himalayas. It yields part of the Himalayan rhubarb. Its stalks make excellent tarts and puddings.

6. \textit{Rheum Rhaponticum}, Linn.; \textit{Common or Rhapontic Rhubarb}.—Grows in Thrace; borders of the Euxine Sea; north of the Caspian; Siberia, &c. Cultivated in this country for the leaf-stalks, which are used for tarts and puddings; whence it is frequently termed \textit{culinary} or \textit{tart rhubarb}. Grown largely at Banbury, in Oxfordshire, on account of its roots, which, when dried, constitute \textit{English} or \textit{Banbury rhubarb}.\(^3\) Cultivated also in France, and yields part of the French rhubarb.

7. \textit{R. Crassinervium}, Fischer.—Habitation unknown. Sent from St. Petersburg to the Apothecaries' Garden, Chelsea. Its roots possess, according to the late Mr. Anderson, the colour and odour of Turkey rhubarb.\(^4\)

II. With \textit{spiciform racemes}.

11. \textit{Rheum Moorcroftianum}, Royle; Small-stalked Rhubarb.—Niti Pass, in the Himalayas. This and the preceding species have denser and more yellow roots than the two other Himalayan species of Rheum above noticed (viz. \textit{R. Emodi} and \textit{R. Webbianum}).

Preparation.—The method of curing or preparing Asiatic rhubarb for the market varies somewhat in different localities. In China it is as follows: The roots are dug up, cleansed, cut in pieces, and dried on stone tables, heated beneath by a fire. During the process, the roots are frequently turned. They are after wards pierced, strung upon cords, and further dried in the sun.\(^5\) In Tartary, the Moguls cut the roots in small pieces, in order that they may dry the more readily, and make a hole in the middle of every piece, through which a cord is drawn, in order to suspend them in any convenient place. They hang them, for the most part, about their tents, and sometimes on the horns of their sheep.\(^6\) Sievers, how-

ever, states that the roots are cut in pieces, strung upon threads, and dried under sheds, so as to exclude the solar rays; and the same author tells us that sometimes a year elapses from the time of their collection until they are ready for exportation. 

1. **Varieties and Description.**—The various sorts of rhubarb (rheischrei) of commerce may be conveniently arranged in four divisions, respectively distinguished as Muscovitic or Russian, Canton, Himalayan, and European.

1. **Muscovitic or Russian Rhubarb** ([Radix Rhei Muscovitici, Ruthenica, vel Rossica]).—Under this head are included those sorts of Asiatic rhubarb which are brought into Europe by way of Russia. The principal and chief sort is the Crown Rhubarb. Two other inferior sorts, called respectively Bucharian and Siberian Rhapontic Rhubarb, are occasionally imported, but are not found in the shops. 

1. **Turkey Rhubarb** (rheischrei turcici), because formerly this description of rhubarb came into Europe by way of Natalia. 

The barter of rhubarb is carried on by the Russian government, under a contract made with Bucharians at Kiachta for ten years, and confirmed by the Chinese government. According to this contract, the Bucharians undertake to furnish a certain quantity of rhubarb annually to the Russian crown, for a certain quantity of goods of a certain quality, and to deliver up all rhubarb not approved of, without remuneration, and permit it to be burnt by the Russian government. 

The rhubarb grows wild in Chinese Tartary, especially in the province Kansu. It is collected on that long chain of mountains of Tartary, destined for the most part of woods, and which arises not far from the town of Selin, and extends to the south as far as the lake Kokonor, near Thibet. It is generally gathered in summer, from plants of six years of age. When the root is dug up it is washed, to free it from earthy particles, peeled, bored through the centre, strung on a thread, and dried in the sun. In autumn, all the dried rhubarb collected in the province is brought in horse-hair sacks, containing about 300 lbs. to Sinin (the residence of the dealers), loaded on camels, and sent over Mongolia to Kiachta, Canton, Macao, and partly to Pekin. All the rhubarb brought to Kiachta undergoes an examination, prescribed by the Imperial Russian Medical Council, according to directions of the Russian government. The selection of the rhubarb bartered for by Russian merchants takes place in the custom-house at Kiachta; and of that for the crown, in a house for that purpose on the Chinese borders. 

In this selection, the following rules are chiefly to be observed:—

a. To reject pieces obtained from dead plants; which are porous, of a gray colour, and besides fibre and oxalate of lime, contain little of the other constituents of rhubarb.

b. To reject pieces that are small, derived from young plants, and which are of a pale colour, and without much virtue.

c. To reject roots of other plants, which are casually or purposely mixed with the rhubarb.

d. To pare the rhubarb. This is done, first, to remove remaining portions of the bark and the upper part of the root; and, secondly, to cleanse those parts that may be stained with the sweat of the camels.

e. To perforate all pieces, and examine their interior.

f. To re-dry those roots which may be moist.

As the rhubarb taken in exchange by the crown is not permitted to be imported into the European part of Russia, except in quantities of 1,000 poods, or 40,000 pounds, the roots approved of, after the examination, are packed in bags, and placed where there is a free current of air, until the necessary quantity has accumulated, which is then packed in cases capable of containing 4—5 poods. These cases are covered with linen and pitched, then sewed into skins and marked with the year of the importation of the root, and sent to Moscow.

Crown rhubarb is imported in chests holding from 156 to 160 lbs. each. Each chest is pitched on the outside and covered with a hempen cloth and a hide. On the outside of the chest is a printed paper, stating the year in which the rhubarb

---

was imported into Russia, and the weight of the chest. The following is a literal copy (reduced in size) of one of these papers:

**RAD: RHEI PALMAT:**

КИТАЙСКИЙ КОПЫТЧАТЫЙ РЕВЕНЬ

ПАРТІЯ 1840ГОДА.

№ 6

ЛИСТАГО ВБСУ 4. - 26

The best prices are obtained for those chests whose rhubarb is in small pieces (for retailing), has a bright colour, and is sound and hard. The shapes of the pieces are various, being angular, rounded, irregular, etc. The flat surfaces and angles which the pieces present show that the cortical portion of the root has been removed by slicing (and not by scraping, as in the Canton rhubarb). Holes are observed in some of the pieces extending completely through; they have been made for the purpose of hanging the pieces to dry; but all traces of the cord have been carefully removed, and the holes scraped or filed to get rid of all decayed portions. The holes which extend only partially through the pieces are borings which have been made to examine the condition of the interior of the pieces.

Externally, the pieces are covered with a bright yellow-coloured powder, usually said to be produced by the mutual friction of the pieces in the chests during their passage to this country; though many druggists believe it is derived from the process of *rouncing* (that is, shaking in a bag with powdered rhubarb), before its exportation. The odour is strong and peculiar, but somewhat aromatic. It is considered by druggists to be so delicate, that in all wholesale drug-houses a pair of gloves is kept in the Russian rhubarb drawer, with which only are the assistants permitted to handle the pieces. When chewed, it feels gritty under the teeth, from the presence of numerous crystals of oxalate of lime; it communicates a bright yellow colour to the saliva, and has a bitter, slightly astringent taste.

Beneath the dust with which the pieces are covered, the surface has a reddish-white tint, owing to the intermixture of white and red parts. The yellowish-white parts have the form of lines or veins, which, by their union with each other, assume a reticular form. Irregularly scattered over the surface we observe small star-like spots and depressions, of a darker colour. The transverse fracture is uneven, and presents numerous brownish-red or dark carmine-coloured undulating veins. The

CHINESE HOOF RHUBARB

OF THE YEAR 1840.

№ 6

NET WEIGHT 4. — 26
longitudinal fracture is still more uneven, and shows the longitudinal direction of the veins, which are often interrupted with white. The surface obtained by cutting is more or less yellow, and often exposes the veins, disposed in groups.

By boiling very thin slices of the root in water, and then submitting them to the microscope, we observe cellular tissue, annular ducts, and numerous conglomerase raphides (clumps of crystals of oxalate of lime). From 100 grs. of Russian rhubarb, the late Mr. Edwin Quekett procured between 35 and 40 grs. of these raphides. ¹ Turpin considered the presence of these crystals sufficient to distinguish Russian and Chinese rhubarb from that grown in Europe; but in some specimens of English rhubarb I have met with them in as great abundance as in foreign rhubarb. According to Raspail, ² they are situated in the interstices of the elongated tissue; but this statement is erroneous, the situation of the crystals being in the interior of the cells.

The small pieces of crown rhubarb are usually picked out and sold as radix rhei turcici electa; the larger pieces and dust being employed for powdering.

The powder of Russian rhubarb is of a bright yellow colour, with a reddish tint; but, as met with in the shops, it is almost invariably mixed with the powder of English rhubarb.

2. White or Imperial Rhubarb.—When Pallas was at Kiachts, the Bucharian merchants, who supplied the crown with rhubarb, brought some pieces of rhubarb as white as milk, with a sweet taste, and the same properties as rhubarb of the best quality. ³ It is not met with in English commerce as a distinct kind; and it is almost unknown in Russia. ⁴ But in the chests of Russian rhubarb there are occasionally found pieces having an unusually white appearance; these I presume to be the kind alluded to. ⁵ White rhubarb is said to be the produce of R. leucorrhizum, Pallas (R. nanum, Sievers.)

3. Taschkent Rhubarb.—This is the refuse of the true Russian rhubarb, which comes by way of Taschkent. It differs but little from the crown rhubarb. On account of its cheapness, it, like the Bucharian sort, is employed for purposes for which the crown rhubarb of Russia is too expensive. I have not met with it in English commerce.

4. Bucharian Rhubarb (Rheum bucharicum.)—Grassman, an apothecary, at St. Petersburg, who has described this sort, ⁶ considers it to be the rhubarb which, according to Pallas, is obtained from Rheum undulatum, and which, in the Pharmacopeia Russica, for 1798, was denounced radix rharbarbi sibirici. As it is not under the control of the crown, in Russia, it undergoes no examination, and inferior and rotten pieces, therefore, are often met with. On account of its cheapness it is used, in Russia, in veterinary medicine.

In 1840, some of it was received here by Mr. Faber, from Russia, to whom I am indebted for samples of it. It is described as being carried into the latter country by way of Nischny, where it is trimmed for the Moscow market.

This kind of rhubarb is intermediate between the Chinese and Russian or Moscovite rhubarb, but of inferior quality. The pieces are, more or less, rounded or flattened, and weigh from one to two ounces each. Some of them appear to have been deprived of their cortical portion by scraping, as in the Chinese rhubarb; but in others, the cortex has been removed by slicing. Most of them are perforated by a hole, apparently for the purpose of drying them; but in none of the holes are there any remains of the cord used in suspending the roots. The holes, moreover, appear to have been cleaned out, as in the Russian rhubarb, for no portion of decayed rhubarb is seen in them. Some of the pieces are dense, but most of them are lighter than good Russian rhubarb. Internally, they are often decayed and dark coloured. Their texture is similar to that of genuine rhubarb. The odour is also like that of rhubarb, but much feebler; the taste is bitter and astringent. When chewed, this rhubarb feels gritty under the teeth. Its colour is darker than that of good Russian rhubarb.

5. Siberian Rhubarb; Rheum sibiricum.—This is the sort which Grassman has described as Siberian rhapontic rhubarb. In 1845, three chests of it came to England from St. Petersberg, under the name of Bucharian rhubarb, and were sold by public sale at 6d. per lb.

⁷ For a notice of this and two preceding varieties, see a paper by the author in the Pharmaceutical Journal, vol. iv. pp. 445 and 500, 1845.
In its general appearance, it agreed with rhubarb grown in this country, and known as English stick rhubarb. It had been decorticated, though imperfectly so, as portions of the dark brown cortex were here and there left adherent. The pieces were all more or less cylindrical, seldom exceeding four inches in length and an inch in diameter, and on the average weighed about 100 grains each; the longest piece was six inches in length, and an inch and a half in diameter. The broadest piece was somewhat flattened, and about three inches in its broadest diameter. Its colour was, in general, darker than that of the ordinary rhubarb, but was of the same kind of tint. Its odour was remarkably sweet, similar to what I have perceived when drying the roots of different species of Rheum cultivated in England. When chewed it was not gritty. Its taste was mucilaginous, bitterish, but not astringent. The fracture of the smaller and sound pieces was similar to that of English stick rhubarb; the larger pieces were decayed, dark brown, and tasteless in the centre.

2. Canton Rhubarb.—This, like the Russian crown rhubarb, is the produce of China, but is exported from Canton. It is usually known in English commerce as Chinese or East Indian rhubarb (radix rhei chinesis seu indica). It is imported either directly from Canton, or indirectly by Singapore and other parts of the East Indies, and is probably the produce of the province of Sê-tehuen (Du Halde), of Hoo-nan and Hoo-pih, as well as of other provinces (Gutzlaff and Reed).

Three kinds of Canton rhubarb are known in commerce; these are, the untrimmed or half-trimmed, the trimmed, sometimes called the Dutch trimmed, and what I have called stick rhubarb.

6. Half-trimmed or untrimmed Canton Rhubarb.—This is usually Chinese or East Indian rhubarb of the shops. It is called "untrimmed," or "half-trimmed," because the cortical portion of the root has been incompletely scraped (not sliced) off; and consequently the pieces have a rounded character, and are devoid of the flat surfaces and angles produced by slicing (as in the Russian and Dutch trimmed rhubarbs). The inferior pieces present the remains of the greenish-brown or blackish cortex. The pieces are frequently cylindrical or roundish, but sometimes flattened; in trade, they are distinguished as rounds and flats. They are generally perforated with holes, in many of which, we find portions of the cords by which they were suspended. These holes are smaller than those observed in Russian rhubarb, and that portion of the root forming their sides is usually dark-coloured, decayed, and of inferior quality. The best pieces are heavier and more compact than that of the Russian kind; and are covered with an easily separable dust. When this is removed, we observe that the surface is not so regularly reticulated, is of a more yellowish-brown than reddish-white colour, and has coarser fibres than Russian rhubarb. On the finer pieces, we notice numerous star-like spots or depressions. The fracture is uneven; the veins, especially towards the middle, have a less determinate direction, and are of a duller or reddish-brown colour, and, in very bad pieces, of an umbervrown colour, with a gray substance between the veins.

The odour of this species is much less powerful than that of Russian rhubarb, and is somewhat less aromatic. The taste, grittiness when chewed, and microscopic appearances, are similar to those of Russian rhubarb. The colour of the powder is of a more dull yellow or brownish cast.

This sort of rhubarb is imported in chests and half chests; the former contains one picul (133½ lbs.), the latter half a picul. The chests are oblong, have been coarsely put together, and, except in shape, resemble tea-chests; and, like the latter, are lined with sheet-lead. The cover is a double one.

When this sort arrives in London, it is hand-picked, tared, and sorted into three qualities—bright and sound, dark and horny, and worm-eaten. This is not done with Russian rhubarb.

7. Dutch-trimmed or Batavian Rhubarb, offic. (Rhubarbe de Perse, Guibourt.)—This kind of rhubarb is closely allied to, if it be not identical with, the preceding in its texture. In commerce, however, it is always regarded as distinct. It is imported from Canton and Singapore in chests, each containing one picul, (133¼ lbs.) It has been dressed or trimmed to resemble the Russian crown rhubarb, which it does in shape, size, and general appearance; for the cortical portion of the
root seems to have been separated by slicing, and hence the pieces have the same angular appearance on the surface that the Russian rhubarb has. The pieces are frequently perforated, and in the holes are found the remains of the cord by which the root has been suspended; in this it differs from the Russian crown rhubarb. In the drug-trade, this kind of rhubarb is said to be trimmed, and, according to the shape of the pieces, they are called flats or rounds. The colour and weight of the pieces are variable.

8. Canton Stick Rhubarb.—In 1844, five cases of this rhubarb were imported from Canton, and were sold by public sale, at 8d. per pound.

All the pieces but one of my sample are cylindrical, about two inches long, from half to three-quarters of an inch in diameter, and weigh each on the average about 100 grains. The piece to which I have referred as forming the exception is shaped like a flattened cylinder, cut obliquely at one end; its greatest length is about two and a half inches, its greatest breadth two inches and a quarter; while its depth is about one inch, and its weight is about two ounces. Mr. Faber, from whom I received it, tells me, that on the examination of a quantity of Canton stick rhubarb he found several such pieces.

Most of the pieces are decorticated. These resemble English stick rhubarb in their texture and colour, except that they are, perhaps, somewhat paler. The taste is bitter, and somewhat astringent, but considerably less so than that of good, half-trimmed, Canton Rhubarb. By chewing it, little or no grittiness is perceptible.

This kind of rhubarb is probably obtained from the root-branches of the plant which yields the usual Canton rhubarb.

3. Himalayan Rhubarb (Radix Rhei Himalayanensis; Radix Rhei Indici).—Rhubarb, the produce of the Himalayas, which makes its way through the plains of India, through Kahlsee, Almora, and Butan, is probably, from its usual dark colour and spongy texture, the produce of either or both R. Emodi and R. Webbia- num; the roots of R. scirpiforme and R. Moorcroftianum being lighter coloured and more compact in structure.

I have met with two sorts of Himalayan rhubarb:

9. Large Himalayan Rhubarb; Rhubarb from Rheum Emodi?—I am indebted to Dr. Wallich for some specimens of this sort of rhubarb. He obtained them from the inhabitants of the Himalayas, who had strung the pieces around the necks of their mules. It has scarcely any resemblance to the officinal rhubarb. The pieces are cylindrical, and are cut obliquely at the extremities; the cortex of the root is not removed; the colour is dark-brown, with a slight tint of yellow; they are without odour, and have a coarse fibrous texture.

In November, 1840, when China rhubarb was very scarce and dear, nineteen chests of Himalayan rhubarb were imported from Calcutta into this country. The chests were of the usual Calcutta kind, made of the hard, heavy, brittle Bengal wood. The weight per chest was gross 1 cwt. 2 qrs. 26 lbs.

The pieces varied considerably in size and shape; some were twisted, cylindrical, furrowed pieces, cut obliquely at the extremities, about four inches long, and an inch and a half in diameter. Others were circular disks, about three inches in diameter, two inches thick, and weighed about four ounces each. Besides these, semicylindrical, angular, and other-shaped pieces were met with, and were obviously obtained by slicing the root. Some of the pieces were decorticated, others were coated. The general colour was dark brown; the prominent decorticated and paler parts having an ochre-brown tint. It had a feeble rhubarb odour, and a bitter astringent taste. When broken, it did not present the marbled texture characteristic of ordinary rhubarb. By chewing it, little or no grittiness was perceived. It was exceedingly light, and worm-eaten.

This was the first shipment of Himalayan rhubarb ever made to this country. Two chests sold at 4d. per lb.; the remainder at 1d. per lb.

10. Small Himalayan Rhubarb; Rhubarb from Rheum Webbianum.—I am indebted to Dr. Royle for this sort. It is the same as that referred to in the ex-

---

2 Dr. Royle (Illust. of the Botany of the Himalayan Mountains, p. 316) says that the Himalayan rhubarb sells for only one-tenth of the price of the best rhubarb, resembling in quality the Russian, and which is found in India.
periments of Mr. Twining. The pieces are short transverse segments of the root-branches, of a dark brownish colour, odourless, or nearly so, with a very bitter astringent taste, and in quality do not essentially differ from the roots given me by Dr. Wallich.

4. European Rhubarb (Radix Rhei Europae).—This is rhubarb cultivated in Europe. The only two sorts with which I am acquainted are the English and French.

11. English Rhubarb (Radix Rhei Anglici).—This is the produce of Rheum Rhaponticum, cultivated in the neighbourhood of Banbury in Oxfordshire.

The history of this rhubarb is not a little curious. It appears that Mr. Wm. Hayward, an apothecary at Banbury, was the original cultivator of rhubarb in that locality. From his own statement it appears that he began to cultivate it about the year 1777. In 1789 he obtained a silver medal, and in 1794 a gold medal, from the Society of Arts, for the cultivation of what he terms "the true Turkey rhubarb;" the plant for which the Society offered the premium being the "R. palmauto, or true rhubarb." Mr. Hayward died in 1811, and his plants were purchased by the father of one of the present cultivators.

At present there are three cultivators of Banbury rhubarb; viz. Mr. R. Usher of Overthorpe and Bodicott, Mr. T. Tustian of Milcombe, and Mr. E. Hughes of Neithorp. These parties grow altogether about 12 acres of rhubarb. Only one species is in cultivation, and that I find to be R. rhaponticum. I have examined specimens of it sent to me by Mr. Rye, surgeon of Banbury, and to the Pharmaceutical Society by Mr. W. Bigg. Mr. Usher states that no other species was ever cultivated at Banbury; and that he cannot produce English rhubarb from the "Giant rhubarb," or any other sort.

At Banbury, the rhubarb is obtained from roots of three or four years old. They are dug up in October or November, freed from dirt, deprived of their outer coat by a sharp knife, exposed to the sun and air for a few days, and dried on basket-work in drying-houses heated by stove-pipes or brick flues. Mr. Hayward accelerated the curing process by scooping a hole in the largest pieces; and dried both these and the smaller pieces strung on packthread, and hung in a warm room.

The root-stock yields the trimmed English rhubarb; the root-branches yield the cuttings or stick English rhubarb. The produce of the process of trimming is called rasings, and serves for powdering.

Trimmed or dressed English rhubarb is the kind frequently observed in the show-bottles of druggists' windows, and was formerly sold in Cheapside and the Poultry for "Turkey rhubarb," by persons dressed up as Turks. It occurs in various-sized and shaped pieces, which are trimmed and frequently perforated, so as to represent foreign rhubarb; some of the pieces are cylindrical in their form, and are evidently segments of cylinders; others are flat. This kind of rhubarb is very light, spongy (especially in the middle of the large flat pieces), attractive of moisture, pasty under the pestle, and has a reddish or pinkish hue not observed in the Asiatic kind. Internally it has usually a marbled appearance; the streaks are pinkish, parallel, and have a radiated disposition; and in the centre of some of the larger pieces the texture is soft and woolly, and may be easily indented by the nail. Its taste is astringent and very mucilaginous; it is not at all, or only very slightly, gritty under the teeth; its odour is feeble, and more unpleasant than either the Russian or East Indian kinds. The microscope discovers it, for the most part, very few crystals of oxalate of lime.

The common stick English rhubarb (called at Banbury the cuttings) occurs in angular or roundish pieces, of about five or six inches long, and an inch thick. When fractured it presents the radiated appearance, and the red-coloured streaks, of the kind last mentioned. Its taste is astringent, but very mucilaginous; it is not gritty under the teeth; it breaks very short.

3 The cultivation of rhubarb in Britain was long since recommended by Sir William Purdyce, in a work entitled The Great Importance and Proper Method of Cultivating and Curing Rhubarb in Britain, for Medical Purposes, London. 1784.
6 For further details see Mr. Bigg's Answers to Queries (drawn up by the author), and the author's Note on Banbury Rhubarb, in the Pharmaceutical Journal, vol. vi. pp. 73, 74, and 76.
English rhubarb is extensively employed by druggists to adulterate the powder of Asiatic rhubarb.

12. French rhubarb (Radix Rhei Gallici).—This kind of rhubarb is procured from Rheum Rhaponticum, undulatum, and especially compactum. These are cultivated at Rheumpole, a place not far from Lorient, in the department of Morbihan. Rheum palmatum is no longer cultivated there. Through the kindness of Professor Guibourt, I possess two kinds of French rhubarb. One of these he calls flat, and is probably the produce of R. rhaponticum; the other he terms round, and is the produce of R. compactum.

COMPOSITION.—Few, if any, articles of the materia medica have been so frequently the subject of chemical investigation as rhubarb. Many chemists have submitted it to examination for the purpose of discovering all its proximate principles. Among these, may be mentioned Schrader in 1807, N. E. Henry in 1814, Brande in 1821, Hornemann in 1822, Peretti in 1826, Buchner and Herberger in 1831, Lucae in 1833, O. Henry in 1836, Brandes in 1836, and Schlossberger and Doepping in 1844.11

But several of the more important chemical examinations of rhubarb have been made with the view chiefly of discovering the one or more active principles of rhubarb. Among these I include the investigations of Trommsdorff, Pfaff, Nami, Caventou, Carpenter, Dulk, and especially of Schlossberger and Doepping, before quoted.

One hundred grains of the finest Russian rhubarb, according to Mr. Brande, lost 44.2 grs. by being repeatedly digested in alcohol (sp. gr. 0.815). By evaporation, the alcoholic solution yielded a residue of 36 grains (the loss 8.2 grs. may be ascribed to water), of which 10 grains (resin?) were insoluble in water.

The rhubarb left after the action of alcohol weighed, when dried at 21°C, 55.8 grs. It yielded to water 31 grs. (gum?). The insoluble residue, weighing 24.8 grs., must have consisted of woody fibre, oxalate of lime, &c.

Schlossberger and Doepping conclude that the flavour, relation to chemical reagents, and therapeutical properties of rhubarb, depend on the conjoint operation of the resin, the colouring matter, the tannin, and the extractive; modified perhaps in some degree by the other ingredients.

1. Odorous Matter of Rhubarb (Volatile Oil).—In none of the analyses of rhubarb is any mention made of a distinct odorous principle; yet it appears to me that such must exist. As the colour and odour bear no proportion to each other in different kinds of rhubarb, it is tolerably clear, that they cannot depend on one and the same principle. The odorous principle is probably a volatile oil, but it has not hitherto been isolated. A few years since, Dr. Bressy announced to the Académie de Médecine that he had separated it, but the committee appointed to repeat his experiments was unable to procure it by his process.1 Zenneck2 says that the rhubarb odour is imitated by a mixture of nitric acid, aloe, and chloride of iron.

2. Yellow Crystaline Granular Matter of Rhubarb. Chrysophanic Acid (so called from rhabar, gold, and event, I shine) ; Rhic Acid. C10H8O4. Found in Russian and Canton rhubarb; in the roots of Rheum Rhipontium and Rumex obtusifolius; and in Parmelia piretina (see ante, p. 69). In the pure or more or less impure state, it has been long known under the names of rhubarbaric acid, rheumia, rhubarberin, and rhein. It may be procured from rhubarb by means of either in Robiquet's displacement apparatus.

Pure chrysophanic acid is a beautiful, clear, yellow, odourless, and tasteless substance, which separates in granular mass, and shows little disposition to crystallize. It is tolerably soluble in hot rectified spirit of wine; not very soluble in ether, even when boiling; and almost insoluble in cold water, but more soluble in boiling water. Heated, it evaporates, emits yellow fumes which condense and form yellow flocculi, and at the same time a part becomes carbonized. It dissolves in alkalies, producing a beautiful red colour; if the potash solution be evaporated to dryness, the red colour changes to violet, and then to a beautiful blue. It dissolves in oil of vitriol, forming a beautiful red solution, from which water precipitates yellow flocculi.

3. Resins. According to Schlossberger and Doeppeing, rhubarb contains three resins, soluble in alcohol, but insoluble in water.

a. Aperitine (from Artemisia, from rum, resin) is a product or deposit of the resin of rhubarb. It is black and shining when dry; slightly soluble in hot spirit, ether, cold and hot water; very soluble in ammonia and potash.

b. Phaorectine (from salic, red brown, and tern, resin); Brown resin of rhubarb. C10H804. It is yellowish brown, very slightly soluble in water and ether; very soluble in spirit and its alkalies, and may be thrown down from the latter solution by the mineral acids.

c. Erythroine (from dihicles, red, and tern, resin); Red resin of rhubarb. C10H804. It is yellow, soluble in ether, very soluble in alcohol; forms rich purple combinations with potash and ammonia, which are very soluble in water. To this resin, as well as to chrysophanic acid, rhubarb chiefly owes its colour.

4. Bitter Principle; Extractive? Rhubarb contains a bitter principle; but most of the substances which have been announced as the bitter principle of rhubarb, under the name of caphoricite (from kaphor, I exude, and wāθ, bitter), or rhabarberin, are themselves compound of two or more principles. Schlossberger and Doeppeing describe the extractive matter of rhubarb as having a bitter taste, but not the flavour of rhubarb.

5. Astringent Matter (Tannic and Gallic acids).—The red veins are the seat of the astringent matter. This is proved by brushing the cut surface of rhubarb with a weak solution of a ferruginous salt; the red veins only undergo a change of colour.

6. Indifferent Substances.—Rhubarb contains a considerable quantity of starch and pectine or vegetable jelly. The starch consists of small grains, with a very distinct nucleus or hilum, and arranged in groups, each of 2, 3, or more grains. Sugar also may be detected by Trommer's test and fermentation (see ante, p. 150). Cellulose and mucilage also are present.

---

2 Pharm. Central-Blatt für 1834, S. 237.
7. **Oxalate of Lime.**—The conglomerate raphides before noticed (see ante, p. 426) are crystals of oxalate of lime. They may be separated in great abundance by boiling Russian or China rhubarb in water until the cohesion of the tissue is completely destroyed. When the decomposed tissue is well shaken with water, the crystals fall to the bottom of the vessel. Heated to redness, they are changed into carbonate of lime. A solution of them in diluted nitric acid, or a solution obtained by boiling the crystals with a solution of carbonate of soda, forms, with nitrate of silver, a white precipitate (oxalate of silver), which explodes when heated. It has been already stated that the late Mr. Edwin Quexett obtained from 35 to 40 per cent. of oxalate of lime from Russian rhubarb.

8. **Rhaponticin.**—A yellow, crystallizable, odourless, tasteless substance, obtained from the root of European (English?) rhubarb. It is insoluble in cold water, ether, and the volatile oils, but soluble in 24 times its weight of boiling water, and twice its weight of absolute alcohol.

**Chemical Characteristics.**—If the powder of rhubarb be heated in a glass capsule over a lamp, an odorous yellow vapour (oil? or resin with chrysophanic acid) is obtained, which communicates a red colour to a solution of caustic potash. The aqueous infusion of rhubarb is rendered green by the sesquichloride of iron (tannogallate of iron); with a solution of gelatin it yields a copious yellow precipitate (tannate of gelatin), which is dissolved on the application of heat, or by the addition of an excess of gelatin; with a solution of disulphate of quinia, a yellowish precipitate (tannate of quinia); with the alkalies (potash, soda, and ammonium), a red-coloured solution (soluble alkaline chrysophanates); with lime-water, a reddish precipitate (chrysophanate of lime); with the acids (the acetic excepted), precipitates; and with various metallic solutions (as of acetate of lead, protochloride of tin, protonitrate of mercury, and the nitrate of silver), precipitates (principally metallic chrysophanates and tannates).

**Distinguishing characteristics of rhubarb and turmeric.**—Paper stained by a strong decoction of tincture of rhubarb is not affected by boric acid, or by the borates rendered acid, whereas turmeric paper is reddened by these agents. Hence the presence of turmeric in powdered rhubarb may be detected by this means.

**Differential characteristics of the commercial sorts of rhubarb.**—All the different commercial sorts of rhubarb contain the same constituents, but in different proportions; hence the differential characteristics are founded on relative or comparative differences, not on absolute ones. English rhubarb usually contains a smaller quantity of crystals of oxalate of lime, and a larger quantity of starch. It, therefore, is less gritty between the teeth. In general, a decoction of Russian, Dutch, or of China rhubarb, becomes, with a solution of iodine, greenish-blue (iodide of starch); after a few minutes the colour disappears, and no iodine can be detected in the liquor by starch, unless nitric acid be previously added. A decoction of English rhubarb, however, is rendered, by a solution of iodine, intensely blue (iodide of starch), the colour not completely disappearing by standing. These peculiarities, however, are not constant. Some specimens of Russian rhubarb, however, contain so much starch that they react on iodine, like those of English rhubarb.

**Physiological Effects.**

*a. On Animals.*—On the solipedes rhubarb acts as a tonic, confining its action principally to the stomach, whose digestive power it augments. On the carnivora it operates, in doses of half a drachm, in the same way; but, in doses of several drachmas, as a purgative. On the larger herbivora it may be given to the extent of several ounces without causing purgation. Tiedemann and Gmelin⁴ detected it by its yellow colour in the serum of the blood of the mesenteric, splenic, and portal veins, and in the urine of dogs to which rhubarb had been administered by the mouth. They failed to recognize it in the chyle.

*b. On Man.*—In small doses (as from four to eight grains) it acts as an astringent tonic, its operation being principally or wholly confined to the digestive organs. In relaxed conditions of these parts it promotes the appetite, assists the digestive process, improves the quality of the alvine secretions, and often restrains diarrhoea. In large doses (as from a scruple to a drachm) it operates, slowly and mildly, as a

---

purgative, sometimes causing slight griping. It never inflames the mucous membrane of the alimentary canal, as jalap, scammony, colocynth, and some other drastic purgatives are capable of doing. The constipation which follows its cathartic effect has been ascribed to the operation of its astringent matter. In febrile complaints and inflammatory diseases it sometimes accelerates the pulse, and raises the temperature of the body; whence the impropriety of its use in these cases.

Under the use of rhubarb the secretions, especially the urine, become coloured by it. According to Heller, the colour which the urine acquires under the employment of this medicine depends on the acid or alkaline condition of this secretion; if acid, it is yellow; if alkaline, it becomes reddish-yellow or blood-red. From Schlossberger’s experiments,¹ it appears that the colour is communicated to the urine by the phaeretine and erythoretine, and not by the chrysophanic acid, which, when pure, neither operates on the bowels nor colours the urine. Urine coloured by rhubarb stains the linen, and is reddened by caustic potash.

The cutaneous secretion (especially of the arm-pits) also becomes coloured under the use of rhubarb. The milk of nurses who have taken it is said to acquire a purgative property.

Rhubarb has for a long period been considered to possess a specific influence over the liver, to promote the secretion of bile, and to be used in jaundice. These opinions, which, as Dr. Cullen² correctly observed, have no foundation either in theory or practice, arose from the absurd doctrine of signatures.

Considered in relation to other medicinal agents, rhubarb holds an intermediate rank between the bitter tonics on the one hand, and the drastics on the other. From the first it is distinguished by its purgative qualities; from the latter, by its tonic operation and the mildness of its evacuant effects. As a purgative, it is perhaps more closely allied to aloe than to any other cathartic in ordinary use; but is distinguished by its much milder operation, and its want of any specific action on the large intestines.

The comparative power of the several kinds of rhubarb has scarcely been ascertained with precision. The remarks above made apply to the Russian and Chinese varieties, whose power is about equal. From experiments made by Dr. Parry, at the Bath Hospital, it appears that the purgative qualities of the English rhubarb are scarcely so strong as those of the Russian and Chinese varieties; but the difference is not great.³ For several years past, English rhubarb has been exclusively employed at the London Hospital; and no complaints have been made respecting its operation. Himalayan rhubarb is, according to Dr. Twining,⁴ almost equal to Russian rhubarb in its purgative effects; but is less aromatic, though more astringent.

Uses.—The remedial value of rhubarb depends on the mildness and safety of its operation, and on its tonic and astringent influence over the alimentary canal.

1. As a purgative.—There are many cases in which the above-mentioned qualities render rhubarb peculiarly valuable as a purgative. In mild cases of diarrhoea it sometimes proves peculiarly efficacious, by first evacuating any irritating matter contained in the bowels, and afterwards acting as an astringent. Given at the commencement of the disease, it is a very popular remedy; and though doubtless it is often employed unnecessarily (since, as Dr. Cullen has justly observed, in many cases no further evacuation is necessary or proper, than what is occasioned by the disease), yet it rarely, if ever, does harm. Sulphate of potash is a very useful adjunct to it, and promotes its purgative operation. Antacids (as chalk or magnesia) are frequently conjointed with it. It is not fitted for inflammatory or febrile cases. As an infant’s purgative it is deservedly celebrated. It is well adapted for a variety of children’s complaints; but is peculiarly adapted to serofulous subjects, and those afflicted with enlargement of the mesenteric glands, accompanied

⁴ VOL. II.—28
⁵ Mat. Med.
with tumid belly and atrophy. Magnesia, sulphate of potash, or calomel may be associated with it, according to circumstances. For an ordinary purgative in habitual constiveness it is scarcely adapted, on account of the constipation which follows its purgative effect.

2. As a stomachic and tonic.—In dyspepsia, accompanied with a debilitated condition of the digestive organs, small doses of rhubarb sometimes prove beneficial, by promoting the appetite and assisting the digestive process. In scrophulous enlargement of the lymphatic glands, in children, rhubarb, in small doses, is often combined with mercurial alteratives (as the hydrargyrum cum creta), or with antacids (as magnesia or chalk), and frequently with apparent advantage.

3. As an external application.—Sir Everard Home used it as a topical application to promote the healing of indolent non-painful ulcers. The powder is to be lightly strewed over the ulcer, and a compress applied. In irritable ulcers an eighth part of opium is to be added. When applied to large ulcers it has produced pretty active purging. The powder of rhubarb, incorporated with salvia and rubbed on the abdomen, proves purgative.

Administration.—The powder of Russian or China rhubarb may be exhibited, as a stomachic and tonic, in doses of from five to ten grains; as a purgative, from a scruple to a drachm. The dose of indigenous rhubarb should be about twice as much as the above.

"By roastng it with a gentle heat, till it becomes friable [rheum torrefactum], its cathartic power is diminished, and its astringency supposed to be increased," (Lewis.)

2. Tinctura Rhei, E. [U. S.]; Tincture of Rhubarb.—(Rhubarb, in moderately fine powder, 3iiij [3iiij, U. S.]; Cardamom Seeds, bruised, 3ss; Proof Spirit [Diluted Alcohol, U. S.] Oij. Mix the rhubarb and cardamom seeds, and proceed by the process of percolation, as directed for tincture of cinchona. This tincture may also be prepared by digestion.)—The alcoholic tincture of rhubarb contains chrysophanic acid, tannin, resin, and uncrystallizable sugar. Cordial, stomachic, and mildly purgative. Dose, as a stomachic, f3ij to f3ijj; as a purgative, f3ss to f3ijj.

3. Tinctura Rhei Composita, L. D.; Compound Tincture of Rhubarb.—(Rhubarb, sliced, 3iiij [3iiij, D.]; Liquorice, bruised, 3vi [3ss, D.]; Saffron 3iiij [3ijj, D.]; [Ginger, bruised, 3ijj, L.; Cardamom Seeds 3i, D.]; Proof Spirit Oij. Macerate for seven [fourteen, D. days, then express and strain.)—Cordial, stimulant, stomachic, and mildly purgative. A popular remedy in various disordered conditions of the alimentary canal, especially at the commencement of diarrhoea, also in flatulent colic. It is a very useful adjunct to purgative mixtures, in cases in which the use of a cordial and stomachic cathartic is required. Dose, as a stomachic, f3ij to f3ijj; as a purgative, f3ss to f3ijj.

1 Pract. Obscr. on the Treatment of Ulcers, p. 96, 1801.
3 Alibert, Nouv. Élem. de Thérap. i. ii. p. 275, et seq. 5me. éd.
4. **TINCTURA RHEI ET ALOES, E. [U.S.]; Tincture of Rhubarb and Aloes.**—(Rhubarb, in moderately fine powder, 3 ss; Socotrine or East Indian Aloes, in moderately fine powder, 5 vj; Cardamom Seeds, bruised, 5 v; Proof Spirit Oij. Mix the powders, and proceed as for the tincture of cinchona.)—[The *U. S. Pharm.* directs Rhubarb, bruised, 3 x; Aloes, in powder, 5 vi; Cardamom, bruised, 3 ss; Diluted Alcohol Oij. Macerate for fourteen days, express, and filter through paper.] A cordial and stomachic purgative, in doses of from 1/3 ss to 1/3 j.

5. **TINCTURA RHEI ET GENTIANE, E. [U.S.]; Tincture of Rhubarb and Gentian.**—(Rhubarb, in moderately fine powder, 3 iij; Gentian, finely cut or in coarse powder, 3 ss; Proof Spirit [Diluted Alcohol, *U. S.*] Oij. Mix the powders, and proceed as directed for tincture of cinchona.)—Stomachic, tonic, and feebly purgative. Dose, as a tonic, 1/3 j to 1/3 iij; as a very mild purgative, 1/3 ss to 1/3 j.

6. **VINUM RHEI, E. D. [U.S.]; Wine of Rhubarb.**—(Rhubarb, in coarse powder, 3 v [3 iij, D.]; Canella, in coarse powder, 5 iij [Proof Spirit 1/3 v, E.]; Sherry Oij and 1/3 xv [Oij, D.]. Digest for seven days, strain, express strongly the residuum, and filter the liquor.)—[Rhubarb, bruised, 3 iij; Canella, bruised, 3 j; Diluted Alcohol 1/3 j; Wine Oij. Macerate for fourteen days, with occasional agitation, then express and filter through paper, *U. S.*—Cordial, stomachic, and mildly purgative. Used in the same cases as the compound tincture of rhubarb. Dose, as a stomachic, 1/3 j to 1/3 iij; as a purgative, 1/3 ss to 1/3 j.

7. **EXTRACTUM RHEI, L. E. D. [U.S.]; Extract of Rhubarb.**—(Rhubarb, powdered, 3 xv; Proof Spirit Oij; Distilled Water Ovij. Macerate for four days with a gentle heat, afterwards strain, and set by, that the dregs may subside. Pour off the liquor, and evaporate it, when strained to a proper consistence, *L.*—The process of the *Edinburgh* and *Dublin Colleges* is as follows: Take of Rhubarb 1bj; Water Ov. Cut the rhubarb into small fragments; macerate it for twenty-four hours in three pints of the water, filter the liquor through a cloth, and express it with the hands or otherwise moderately; macerate the residuum with the rest of the water for twelve hours at least; filter the liquor with the same cloth as before, and express the residuum strongly. The liquors, filtered again, if necessary, are then to be evaporated together to a proper consistence in a vapour-bath. The extract, however, is obtained of finer quality by evaporation in a vacuum with a gentle heat.)—[The *U. S. Pharm.* directs Rhubarb, in coarse powder, 1bj; Diluted Alcohol a sufficient quantity. Mix the Rhubarb with an equal bulk of coarse sand, moisten it thoroughly with Diluted Alcohol, and having allowed it to stand for twenty-four hours, put it into a percolator, and add Diluted Alcohol gradually until four pints of filtered liquor are obtained; then, by means of a water-bath, evaporate to the proper consistence.]

The Edinburgh and Dublin Colleges, it will be observed, employ no spirit in the above process. Great care is required in the preparation of this extract, as both the purgative and tonic properties of rhubarb are very apt to become deteriorated by the process. I have some extract prepared in *vacuo* more than twenty years ago, which still preserves the proper odour and flavour of rhubarb. The dose of extract of rhubarb, as a purgative, is from grs. x to 3 ss.

8. **EXTRACTUM RHEI FLUIDUM, U. S.; Fluid Extract of Rhubarb.**—(Take of Rhubarb, in coarse powder, 3 viij; Sugar 3 v; Tincture of Ginger 3 ss; Oil of Fennel, Oil of Anise, each m iv; Diluted Alcohol a sufficient quantity. To the Rhubarb, previously mixed with an equal bulk of coarse sand, add twelve fluidounces of Diluted Alcohol, and allow the mixture to stand for twenty-four hours. Transfer the mass to a percolator, and gradually pour upon it Diluted Alcohol until the liquid which passes has little of the odour or taste of the rhubarb. Evaporate the tincture thus obtained, by means of a water-bath, to five fluidounces; then add the sugar, and after it is dissolved, mix thoroughly with the resulting fluid extract, the tincture of ginger holding the oils in solution.—This is an excellent and efficient preparation
in doses of $\frac{3}{j}$—ij. It may be given to children in small doses. By addition to magnesia it constitutes an effective combination.]

9. Philæ Rhei, E. [U. S.]; Rhubarb Pills.—(Rhubarb, in fine powder, nine parts; Acetate of Potash one part; Conserve of Red Roses five parts. Beat them into a proper mass, and divide it into five-grain pills.)—[Rhubarb, powdered, $\frac{5}{j}$; Soap $\frac{5}{s}$; Make a mass with water, and divide into 120 pills. The soup renders them antacid, U. S.]-Stomachic and purgative. The acetate of potash is employed, I presume, to prevent the pills becoming hard by keeping. Each pill contains nearly three and a half grains of rhubarb.

10. Pilulae Rhei Compositæ, L. E. [U. S.]; Pilulae Rhei Composite, D.; Compound Pills of Rhubarb.—(Rhubarb, powdered, $\frac{5}{v}$ [twelve parts, E.]; Aloes, powdered, $\frac{3}{ii}$ [nine parts, E.]; Myrrh, powdered, $\frac{3}{ij}$ [six parts, E.]; Soap $\frac{3}{ss}$ [six parts, E.]; [Oil of Caraway $\frac{1}{x}$v, L., Oil of Peppermint one part, E.]; Treacle, q. s. [Conserve of Red Roses five parts, E.]. Mix them, and beat them into a proper mass [and divide this into five-grain pills. The U. S. Pharm. directs Rhubarb, in powder, $\frac{3}{i}$; Aloes, in powder, $\frac{5}{v}$; Myrrh, in powder, $\frac{3}{s}$; Oil of Peppermint $\frac{3}{ss}$. Beat them with water so as to form a mass, to be divided into two hundred and forty pills.] This pill may be also made without oil of peppermint, when so preferred, E. The Dublin College orders of Rhubarb, in fine powder, $\frac{3}{ss}$; Hepatic Aloes, in fine powder, $\frac{3}{ix}$; Myrrh, in fine powder, Castile Soap, of each, $\frac{3}{vi}$; Oil of Peppermint $\frac{5}{j}$; Treacle, by weight, $\frac{3}{ij}$.—Tonic and mildly purgative. Dose, $\frac{3}{j}$, or two to four pills.

11. Philæ Rhei et Ferris, E.; Pills of Rhubarb and Iron.—(Dried Sulphate of Iron four parts; Extract of Rhubarb ten parts; Conserve of Red Roses about five parts. Beat them into a proper pill mass, and divide into five-grain pills.)—Tonic. Dose, two to four pills.

12. Pulvis Rhei Compositus, E. D.; Compound Powder of Rhubarb.—(Magnesia, $\frac{3}{j}$; Ginger, in fine powder, $\frac{3}{ij}$ [D.]; Rhubarb, in fine powder, $\frac{3}{j}$; D.]. Mix them thoroughly, and preserve the powder in well-closed bottles.—A very useful antacid and mild stomachic purgative, especially adapted for children. Dose, for adults, $\frac{3}{j}$ to $\frac{3}{ss}$; for children, gr. $v$ to gr. $x$.

13. Syrupus Rhei, U. S.; Syrup of Rhubarb.—(Take of Rhubarb, bruised, two ounces; Boiling Water a pint; Sugar two pounds. Macerate the rhubarb in the water for twenty-four hours and strain; then add the sugar, and proceed in the manner directed for syrup.)—This is a mild astringent and laxative, and may be used in bowel affections. The dose is from $\frac{3}{j}$ to $\frac{3}{2}$.

14. Syrupus Rhei Aromaticus, U. S.; Aromatic Syrup of Rhubarb; Spiced Syrup of Rhubarb.—(Take of Rhubarb, bruised, two ounces and a half; Cloves, bruised, Cinnamon, bruised, each half an ounce; Nutmeg, bruised, two drachms; Diluted Alcohol two pints; Syrup six pints. Macerate the rhubarb and aromatics in the diluted alcohol for fourteen days, and strain; then, by means of a water-bath, evaporate the liquor to a pint, and, while it is still hot, mix it with the syrup previously heated; or it may be made by displacement.)—This syrup is cordial, carminative, and slightly laxative. It is well adapted to weak and relaxed conditions of the bowels, as in chronic diarrhoea, dysentery, and infantile bowel complaints, with feeble action. The dose is $\frac{3}{j}$ to $\frac{3}{ss}$.

151. RUMEX ACETOSA, Linn.—COMMON SORREL.

Sex. Syst. Hexandria, Trigynia.

(Folia.)

History.—Dioscorides* mentions this as the fourth sort (τετάρτον ἱδρον) of λάπαδον, which some call δοξάς.

* Lib. ii. cap. 140.
BOTANY. **Gen. Char.**—Sepals 6, the 3 inner (petals) larger, subsequently becoming enlarged (enlarged or permanent petals), converging, and finally concealing the nut. *Stamen* 6. *Stigma* in many fine tufted segments. *Embryo* lateral.

**Sp. Char.**—Leaves oblong, sagittate or hastate, veiny. *Flowers* dioecious. *Inner sepals* (petals) roundish, cordate, with a very minute tuberel at the base.

**Description.**—Sorrel leaves have an agreeable, acid, slightly astringent taste.

**Composition.**—I am unacquainted with any analysis of this plant. The leaves are composed of *superoxalate of potash*, tartaric acid, mucilage, *fucula*, chlorophyll, *tannic acid*, and woody fibre.

**Physiological Effects.**—Slightly nutritive. Refrigerant and diuretic. Esteemed antiscorbutic.

**Uses.**—Employed as a pot-herb and salad—from the latter use of it, it has been termed *green-sauce*. Rarely applied medicinally. A decoction of the leaves may be administered in whey, as a cooling and pleasant drink, in febrile and inflammatory diseases. In some parts of Scandinavia bread is made of it in times of scarcity.

But the use of aliments containing oxalic acid may, as suggested by Laugier, under some circumstances, dispose to the formation of mulberry calculi.

152. *RUMEX HYDROLAPATHUM*, Hudson.—**GREAT WATER DOCK.**

*Rumex aquaticus*, D.

*Sex. Syst.* Hexandria, Trigynia.

(Radix.)

**History.**—This is not the *R. aquaticus* of Linnaeus.

**Botany.** **Gen. Char.**—See *Rumex Acetosa*.

**Sp. Char.**—*Inner sepals* (petals) ovate-triangular, entire or slightly toothed, all tuberelated. *Racemes* panicked, leafless. *Leaves* lanceolate, narrowed at the base; petiole flat on the upper side.—*Stem* 3—5 feet high. Leaves often more than a foot long.

**Description.**—The herb and root were formerly used under the name of *herba et radix britannica*. The root is inodorous, but has an acrid bitter taste. The flowers are called, by Pliny, *vibones*.

**Composition.**—I am unacquainted with any analysis of the plant. The root contains *tannic acid*.

**Physiological Effects.**—The root is astringent, and is reputed antiscorbutic.

**Uses.**—SCarcely employed. Has been exhibited internally in scurvy, skin diseases, and rheumatism. The powdered root has been used as a dentifrice; the decoction of the root as an astringent gargle for ulcerated or spongy gums. The druids entertained a superstitious veneration for this plant.

153. *POLYGONUM BISTORTA*, Linn.—**GREAT BISTORT OR SNAKE-WEED.**

*Sex. Syst.* Octandria, Trigynia.

(Radix.)

**History.**—It is doubtful by whom this plant is first mentioned. It was certainly noticed by the herbalists of the 16th century.

---

1 Withering, *Bot. vol. ii.*
VEGETABLES.—NAT. ORD. SALSOLACEAE.

BOTANY. Gen. Char.—Calyx 4—5-cleft, more or less coloured. Stamens 5—8, in 2 rows, generally with glands at the base. Styles 2—3, more or less united at the base. Nut 1-seeded, lenticular or 3-cornered, enclosed by the calyx. Embryo lateral, incurved; cotyledons not contorted.

Sp. Char.—Stem simple. Leaves oblong-ovate, somewhat cordate and wavy; petioles winged. Spike dense, terminal.—Flowers flesh-coloured. Stem 1—1 1/2 foot high.

Description.—Bistort root (radix bistortae) is twice bent on itself—hence its name, from bis, twice; and torto, twisted or bent. It is rugous and brown externally; reddish internally; almost inodorous; it has an austere, strongly astringent taste.

Composition.—This root has not been analyzed. The principal constituents are tannic acid, starch, oxalate of lime, colouring matter, and woody fibre.

Physiological Effects.—The local effect is that of a powerful astringent, depending on the tannic acid which it contains; its remote effects are those of a tonic (see vol. i. p. 243). The presence of starch renders the root nutritive—hence in Siberia it is roasted and eaten.

Uses.—It is but little employed. A decoction of the root is sometimes employed as an astringent injection in leucorrhoea and gleet; as a gargle in spongy gums and relaxed sore-throat; and as a lotion to ulcers attended with a profuse discharge.

Internally it has been employed, in combination with gentian, in intermittents. It has also been used as an astringent in passive hemorrhages and chronic alvine fluxes.

Administration.—The dose of the powder is from 5j to 5ss. The decoction (prepared by boiling 3j of the root in Qjss of boiling water) may be administered in doses of from f3j to f3j.

ORDER XXXIX. SALSOLACEAE, Moquin.—SALTWORTS.

CHENOPODiACEae, Lindl.

Characters.—Calyx deeply divided, persistent, with an imbricated rafination. Corolla 0. Stamens usually inserted into the receptacle or base of the calyx, opposite the segments of the latter, and equal to them in number or fewer. Staminalia (squammula hypogynes) in a few genera, very minute, alternate between the filaments and with the segments of the calyx. Ovary single, superior, or occasionally adhering to the tube of the calyx, with a single amphitropical ovule attached to the base of the cavity; style in 2 or 4 divisions, rarely simple; stigmas undivided. Fruit membranous, utricle, sometimes a Caryopsis, rarely a berry. Seed with or without farinaceous albumen; embryo curved or annular (cykloboes), or in a flat spiral (spiralo- bex).—Herbs or under-shrubs sometimes joined. Leaves usually alternate, without stipules. Flowers very small, regular, hermaphrodite or sometimes by abortion unisexual. (From Lindley chiefly.)

Properties.—The plants of this family are characterized by the large quantity of alkali which they contain, and which is combined with an organic acid. Those which inhabit salt marshes are called halophytes (from 2α, salt, and φυτον, a plant), and by combustion yield barilla (see vol. i. p. 514). Those in most common use for this purpose belong to the genera Salsola, Salicornia, and Chenopodium.

Many of the plants are esculent, and some of them are used as pot-herbs or salads; as spinach (Spinacea oleracea) and beet (Beta vulgaris). The latter is extensively cultivated and employed as a source of sugar; and a variety of it, called Mangold-Wurzel, is used for feeding cattle. The seeds of Chenopodium Quinoa are employed in Peru as food, under the name of petty rice; their starch grains are the smallest known.

Volatile oil is found in several, which owe their aromatic, carminative, stimulant, and anthelminthic properties to it.

*Sex. Syst.* Pentandria, Digynia.

(Chenopodium, U. S. Wormseed. The fruit of the plant.)

**Gen. Char.—**Calyx five-parted, with five angles. Corolla none. Style bifid, rarely trisep. Seed one, lenticular, horizontal, covered by the closing calyx. (Nuttall.)

**Sp. Char.—**Leaves oblong, lanceolate, sinuate, and dentate, rugose. Racemes naked. Style one, three-cleft (Elliot).

The common names by which this plant is known in the United States are Jerusalem Oak, Wormseed, Goosefoot, and Stinkweed.

**Description.—**The root of the plant is perennial and branched. Stem upright, herbaceous, much branched, deeply grooved, from two to four feet high. Branches fastigate, giving to the plant a shrubby appearance. Leaves sessile, scattered, and alternate, attenuate at each end, with strongly marked nervures, oval or oblong, deeply sinuate, studded beneath with small globular, oleaginous dots. Flowers small, numerous, of a yellowish-green colour, and collected in long, axillary, dense, leafless spikes.

**Hab.—**This species of Chenopodium is found in most parts of the United States. It grows in old fields, along roadsides, in moist and sandy situations. It flowers in June and July; and from August until cold weather the seeds may be collected.

The seeds are small, not larger than the head of a common-sized pin, irregularly spherical, very light, of a dull greenish-yellow colour, approaching to brown, and having a bitterish, somewhat aromatic, pungent taste. The odour and taste are due to the volatile oil that they contain; this is found in other parts; in fact, the whole plant contains it, and hence the uniform flavour possessed by them.

The properties of the seeds are vermifuge, which appears to have been known soon after the establishment of the British Colonies in America, especially in Virginia, where they were first used for this purpose. The herb is spoken of by Schoepf and Kalm, with others, in terms of commendation. The vermifuge power, by long trial, has been decidedly proved. As an antispasmodic it has also been used. Plenck employed it with success in five or six cases of chorea (Griffith, *On Chen. Anthel. in Am. Journ. of Pharmacy*, vol. v. p. 180), and this success has been confirmed by other writers.

The Chenopodium anthelminticum has sometimes been confounded with the C. ambrosioides, which is a smaller plant, and distinguished by the leafy spikes of flowers. The sensible properties are similar.

The seeds are given in the form of an electuary, pulverized and mixed with molasses or syrup; but the quantity required to be taken is liable to produce nausea and sickness. Dose $\frac{1}{2}$ to $\frac{1}{4}$ given twice or thrice daily.

The expressed juice is sometimes administered; the dose is $\frac{1}{2}$; or a decoction of the leaves may be employed; this is best prepared with milk, in the proportion of $\frac{3}{4}$ leaves to $\frac{1}{2}$ of milk or water. It may be flavoured with aromatics.

**Oleum Chenopodi, U. S.; Oil of Wormseed.—**This oil is of a light yellow colour when distilled, but its colour deepens by age and exposure. It has in a high degree the flavour of the plant. Its sp. gr. is 0.908. It is obtained by distilling the seeds; but the whole plant may be used for this purpose, as the oil is abundant in the glands. Sometimes it is adulterated with spirit of turpentine, or other inferior volatile oils; this must be determined by the odour. From the readiness with which it may be given, it is the best for exhibition, as it possesses the vermifuge properties in the smallest possible compass. The dose is from 10 to 20 drops on a lump of sugar, or in emulsion. After several doses have been given, a purgative, as castor-oil, may be interposed.—J. C.]
VEGETABLES.—NAT. ORD. LABIATÆ.

155. Chenopodium Vulvaria, Linn.—Stinking Orache.

Sex. Syst. Pentandria, Digynia.

(herba.)

Chenopodium oldorum, Smith, Eng. Flora. Atriplex satida, Cullen, Mat. Med. vol. ii. p. 365. Stinking Goosefoot. Indigenous. Cultivated at Mitcham. Sold in the herb-shops as a popular emmenagogue and “strengthener of the womb.” In the fresh state it has a nauseous taste, and a strong offensive odour like that of putrid fish. By drying, it loses its smell, and probably its medicinal qualities also. Dr. Houlton and Mr. Churchill¹ declare that the popular notion of its emmenagogue powers is well founded. Dr. Cullen regarded it as a powerful antispasmodic in hysteria. The recent plant has been used in the form of infusion or tea, and conserve. Mr. Churchill gave the insipsated juice or extract in doses of from five to fifteen grains.

Chenopodium ambrosioides, Linn., is said to be used indiscriminately with the preceding. Its odour is weaker and less offensive.

Chenopodium Botrys, Linn., is also esteemed anthelmintic.

SUBDIVISION II. COROLLIFLORÆ, De Cand.

Monopetalæ corolla hypogyna, Juss., et corolla perigyna (partim).

Gamopetalæ, Endl. (partim).

Calyx gamosepalus, i. e. sepals more or less united at the base. Petals mostly united, distinct at the base from the calyx. Stamens usually adnate to the corolla. Ovary mostly free, rarely adnate to the calyx.

ORDER XL. LABIATÆ, Jussieu.—LABIATES.

Lamiaceæ, Lindley.

Characters.—Calyx tubular, inferior, persistent, the odd tooth being next the axis; regular 5- or 10-toothed, or irregular bilabiate or 3- to 10-toothed. Corolla monopetalous, hypogynous, bilabiate; the upper lip undivided or bifid, overlapping the lower, which is larger and 3-lobed. Stamens 4, didynamous, inserted upon the corolla, alternately with the lobes of the lower lip, the 2 upper sometimes wanting; anthers 2-celled; sometimes apparently unilocular in consequence of the confluence of the cells at the apex; sometimes one cell altogether obsolete, or the 2 cells separated by a bifurcation of the connective. Ovary deeply 4-lobed, seated in a fleshy hypogynous disk; the lobes each containing 1 erect ovule; style 1, proceeding from the base of the lobes of the ovary; stigma bifid, usually acute. Fruit, 1 to 4 small nts, inclosed within the persistent calyx. Seeds erect, with little or no albumen; embryo erect; cotyledons flat. Herbaceous plants or undershrubs. Stem 4-cornered, with opposite ramifications. Leaves opposite, divided or undivided, without stipules, replete with receptacles of aromatic oil. Flowers in opposite, nearly sessile, axillary cymes, resembling whorls; sometimes solitary, or as if capitate (Lindley).

Properties.—The medicinal activity of the plants of this family depends on volatile oil, bitter extractive, and astringent matter.

The volatile oil resides in small receptacles (by some called globular glands) contained in the leaves. These glands are placed quite superficially, or rather in depressed points, and are commonly of a shining yellow colour. We may regard them as oleo-resinous matter separated from glands lying on the under surface. When macerated in strong spirit of wine they remain unchanged, and appear under the microscope as transparent, probably cellular, vesicles, filled with a yellow granular matter."²

The bitter extractive is found, in a greater or less quantity, in all the Labiatae. It is this principle which communicates the bitterness to the watery infusion of these plants.

The presence of astringent matter is shown by the green colour produced when a ferruginous salt is added to the infusion of some of the Labiatae.

The volatile oil gives to these plants aromatic, carminative, and slightly stimulant properties. The bitter extractive renders them tonic and stomachic. The astringent matter is usually in

¹ Stephenson and Churchill's Medical Botany, vol. iv. pl. clxxvi. 1831.
too small a quantity to communicate much medicinal activity, though it must contribute to the tonic operation.

The perfumer uses some labiate plants on account of their fragrant odour; the cook employs others for their flavour and condimentary properties; the medical practitioner administers them to relieve nausea and colicky pains, to expel wind, to cover the taste of nauseous medicines, and to prevent or relieve griping pains.

The following species, enumerated by London,¹ are cultivated in this country as sweet herbs: Common or Garden Thyme (Thymus vulgaris, Linn.), Lemon Thyme (T. citridorus, Schreb.), Sage (Salvia officinalis, Linn.), Clary (S. Scharea, Linn.), Peppermint (Mentha piperita, Linn.), Spearmint (M. viridis, Linn.), Pennyroyal (M. Pulegium), Common Marjoram (Origanum vulgare, Linn.), Winter Sweet Marjoram (O. heracleoticum, Linn.), Sweet Marjoram (Majorana hortensis, Mencn.), Pot Marjoram (M. Onites, Benth.), Winter Savory (Satureia montana, Linn.), Summer Savory (S. hortensis, Linn.), Sweet or Larger Basil (Ocrimun Basilicum, Linn.), Bush or Least Basil (O. minimum, Linn.), Rosemary (Rosmarinus officinalis, Linn.), and Garden Lavender (Lavandula vera, De Cand.). Some of these species have been, or are, used in medicine, and several of them are officinal.

Besides the labiate plants contained in the British pharmacopeias and to be noticed, a considerable number of other species have been at different times introduced into medicinal use. Some of these are deficient in volatile oil, but abound in a bitter principle, on which account they have been employed as stomachics and tonics; such are Water Germander (Teucrium Scordium, Linn.), Wall Germander (T. Chamaedrys, Linn.), and Ground Pine (Alouga Chamapipy, Smith); the last two of which have been used, as I have before mentioned, as anti-arthritic remedies (see ante, p. 387). Others abound in essential oil, and are consequently more aromatic, stimulant, and carminative; such are Cat-Thyme (Teucrium Marum, Linn.), Common Hysop (Hyssopus officinalis, Linn.), Ditany of Crete (Amaracus Dictamus, Benth.), &c. Teucrium Polium has been used in diarrhoea, dysentery, and cholera.

⁰ Tribe I. Ocmioideae, Bentb.

Lavandula angustifolia, Ehrenberg. L. spica, var. a, Linn.

Sex. Syst. Didynamia, Gymnosperma.

(Oleum e flore distillatum, L. D.—The flowering heads; and volatile oil of ditto, E. The flowers, D.)

History.—No plant is mentioned, under the name of Lavender, by Hippocrates, Theophrastus, Dioscorides, or Pliny. It is not improbable, however, that lavender may be alluded to, under some other name, by one or more of these authors; but it is impossible now to identify it with any certainty. Sprengel² declares, on the authority of Hesychius, that the ιφου of Theophrastus³ is Lavandula Spica. The σιτρυς or στοξας of Dioscorides,⁴ the stecchas of Pliny,⁵ is the L. stecchas, Linn.

Botany. Gen. Char.—Calyx ovate-tubular, nearly equal, 13 or rarely 15-ribbed, shortly 5-toothed, with the 4 lower teeth nearly equal, or the 2 lower narrower; the upper either but little broader than the lateral ones, or expanded into a dilated appendage. Corolla with the tube exserted, the throat somewhat dilated, the limb oblique and bilabiate; upper lip 2-lobed; lower 3-lobed; all the divisions nearly equal. Stamens 4, inclosed in the tube of the corolla, bent downwards. Filaments smooth, distinct, not toothed. Style shortly bifid at the apex; the lobes complanate, subconnate. Disk concave, with 4 fleshy scales at the margin. Nuts smooth, adnate to the scales of the disk (Bentham).

Sp. Char.—Leaves oblong-linear or lanceolate, quite entire, when young hoary and revolute at the edges. Spikes interrupted. Whorls of 6 to 10 flowers. Floral leaves rhomboid-ovate, acuminate, membranous, all fertile, the uppermost

¹ Encyl. of Gardening.
² Hist. Pl. lib. vi. cap. 6.
⁴ Hist. Reï Herb. t. i. p. 90.
⁵ Lib. iii. cap. 31.
shorter than the calyx. Bracts scarcely any (Bentham).—An undershrub 1 to 2 feet high. Flowers purplish-gray.

Hab.—South of Europe. Extensively cultivated at Mitcham, in Surrey, from which place the London market is chiefly supplied.

Lavandula Spica, De Cand. (L. latifolia, Villars) or French Lavender, formerly considered as a variety only of the preceding species, is not used in medicine. It is distinguished by its lower habit, white colour, the leaves more congested at the base of the branches, the spike denser and shorter, the floral leaves lanceolate or linear, and the presence of bracts (Bentham). It yields by distillation oil of spike (oleum spicae) sometimes called foreign oil of lavender, or, in order to distinguish it from the oil of Lavandula Stoechas, the true oil of spike (oleum spicae verum). This oil is distinguished from the genuine oil of Lavandula vera by its darker green colour, and its less grateful odour. It is used by painters on porcelain, and by artists in the preparation of varnishes.

Properties.—Lavender flowers (flores lavandulae) have a bluish-gray colour, a pleasant odour, and a pungent bitter taste. The flowering stems are collected in June or July, dried in the shade, and made up into bundles for sale. A cold infusion of the flowers is deepened in colour (tannate of iron) by sesquichloride of iron.

Composition.—The principal constituents of the flowers are volatile oil, resin (?), tannic acid, a bitter principle, and woody fibre.

Physiological Effects.—The flowers are carminative, mildly stimulant, and somewhat tonic. Kraus¹ says that when taken internally they cause griping.

Uses.—Lavender flowers are sometimes employed as errhines. They enter into the composition of the pulvis asari compositus (see ante, p. 387).

1. Oleum Lavandule, E. D. [U. S.]; Oleum Lavandule (Anglicum), L.; Oleum Lavandulae verae; English Oil of Lavender, offic. (Prepared by submitting lavender flowers to distillation with water.)—It has a pale yellow colour, a hot taste, and a very fragrant odour. Its sp. gr. varies from 0.877 to 0.905; the lightest oil being the purest. It boils at 397° F.; and is composed, according to Dr. Kane, of C₁₁H₄₈O₂. 1 lb. of oil is obtained from 50 to 70 lbs. of the flowers. 1973 lbs. of the flowers carefully separated from the stalks, yielded Mr. Jacob Bell² at 13 distillations, 28 1/2 lbs. of oil; or 1 lb. of oil from 69 1/2 lbs. of flowers. When the stalks and leaves are distilled with the flowers, the odour of the oil is considerably deteriorated.³ It is a stimulant and stomachic, and is sometimes given in hysteria and headache; but is more commonly employed as a perfume for scenting evaporating lotions, ointments, liniments, &c.—Dose, gtt. jj to gtt. v.

2. Spiritus Lavandule, E. [U. S.]; Spirit of Lavender.—(Fresh Lavender Bbisses; Rectified Spirit Cong. j. Mix them, and, with the heat of a vapour-bath, distil over seven pints. The dried flowers may be substituted for the fresh ones. Druggists frequently prepare this compound by dissolving a few drops of oil of lavender in a fluidounce of rectified spirit. Employed only in the preparation of the Spiritus Lavandulae composita, E.

Lavender Water.—The fragrant perfume sold in the shops, under the name of lavender water (aqua lavandulae) is a solution of the oil of lavender and of other odoriferous substances in spirit. It is in fact, therefore, a compound spirit of lavender; but this name is already appropriated to another preparation. There are various formulas for its preparation, scarcely two manufacturers adopting precisely the same one. The following yields a most excellent product: Oil of Lavender, Oil of Bergamot, aq. fijij; Orris of Roses, Oil of Cloves, aq. gtt. vj; Musk gr. ij; Oil of Rosemary fijij; Honey fijij; Benzoinic Acid fijij; Rectified Spirit Oj; Distilled Water fijij. Mix, and after standing a sufficient time (the longer the better), filter. This agreeable perfume may be employed for scenting spirit-washes, &c., but is principally consumed for the toilet.

3. Tinctura Lavandule Composita, L. D.; Spiritus Lavandulae compositus, E. [U. S.]; Lavender Drops or Red Lavender Drops, offic.—(Oil of Lavender fijij; fijij, D.); Oil of Rosemary m. x fijij, D.); Cinnamon, bruised, fijij fijij, D.); Nut-

meg, bruised, $5ijs$ $[5ijs$, $D.]$; [Red Sanders Wood, cut, $3v$, $L.$; Cochineal, in powder, of each $5ijs$, $D.$]; Rectified Spirit Oij. Macerate the cinnamon, nutmeg, and red sanders wood in the spirit for seven [fourteen, $D.$] days; then express, filter, and to the filtered liquor add the oils, $L.$—Spirit of Lavender Oij; Spirit of Rosemary $f5ixij$; Cinnamon, in coarse powder, $5ijs$; Cloves, bruised, $5ijs$; Nutmeg, bruised, $3ijs$; Red Sandal Wood, in shavings, $5iij$. Macerate for seven days, and strain the liquor through calices, $E.$—[The U. $S.$ Pharm. directs Spirit of Lavender Oij; Spirit of Rosemary Oij; Cinnamon, bruised, $5i$; Cloves, bruised, $5ijs$; Nutmeg, bruised, $3ijs$; Red Sanders, rasped, $5iij$. Macerate for fourteen days and filter through paper.]—Stimulant, cordial, and stomachic. Employed to relieve gastric uneasiness, flatulence, low spirits, languor, faintness, &c. A favourite remedy with hysterical and hypochondriacal persons.—Dose, from $f5ijs$ to $f5iij$, administered in water or on sugar. The red sanders wood is merely a colouring ingredient.

TRIBE II. SATUREEEAE, Benth.

Stamens distant, straight, straggling, or converging under the upper lip, 4 or 2 (in that case the anthers 2-celled and the connective not filiform). Lobes of the corolla flat.

157. Pogostemon Patchouli; Pellet.—Pucha-Pat, or Patchouli.

Sex. Syst. Didynamia, Gymnosperma.

(Offic.)

A pubescent undershrub. Branches vague, decumbent or ascending. Leaves with stalks, opposite, rhomboid-ovate, somewhat obtuse; the lobes crenato-dentate. Spikes terminal and axillary, dense, pedunculated, interrupted at the base. Bracts ovate. Calyx hisrate, twice as long as the bracts, with lanceolate teeth. Corolla bilabiata, smooth and whitish. Stamens 4, didynamous, nearly equal in length; the filaments bearded with violet or bluish purple hairs; the anthers pale yellow, after flowering whitish. Style pale purplish, whitish at the lower part, at the apex deeply cleft. Ovaries 4, distinct.—A native of Silhet, Penang, and the Malayan peninsula.

The wild plant is collected at Penang and the Malayan peninsula, and dried in the sun. If too much dried, it becomes crisp and brittle, and is liable to crumble to dust in packing.

The dried tops (summitae patchouli) are imported into England in boxes of 110 lbs. each, and in half boxes. They are a foot or more in length. The large stems are round and woody, and, when cut transversely, show the pith surrounded with a thick layer of wood, which is remarkable for its distinct medullary rays; the smaller branches are obscurely 4-angled. The leaves are covered, especially on their inferior surface, with a soft pulpy pubescence, which gives the plant a grayish appearance. The colour is strong, persistent, peculiar, and somewhat analogous to that of Cenopodium anthelminticum. It is said to smell more strongly in dry than in damp places. One writer describes the smell of it as being dry, mucilaginous, or earthy; and states that the Chinese or Indian ink owes its characteristic colour to it. The taste of the dried plant is very slight.

The plant, which has not been analyzed, contains volatile oil, green resin, extractive matter, and tannin. By distillation it yields about 2 per cent. of volatile oil (essential oil of patchouli), which possesses the odour of the herb.

Patchouli is almost exclusively used as a perfume. To its excessive employment, ill effects have been ascribed. "Very recently," says a French writer, "a young lady was seized with a passion for patchouli. Her linen, her dresses, and her furniture, were saturated with it. In a short time she lost her appetite and sleep; her complexion got pale, and she became subject to nervous attacks." In India, patchouli is used as an ingredient in tobacco for smoking. The sachets de patchouli of the perfumers consist of a few grains of the coarsely-powdered herb mixed with cotton wool and folded in paper. Placed in drawers, they are said to drive away

1 Annales de Thérapeutique pour 1847, p. 75.
2 For some remarks on the sensitiveness of some female constitutions to odorous emanations, see ante, vol. i. p. 66.
insects from linen, shawls, &c. *Oil of patchouli* is in common use in India for imparting the peculiar fragrance of the leaf to clothes among the superior classes of natives. *Essence de patchouli* is used by perfumers principally for mixing with other scents in the preparation of compounded perfumes, for which purpose it is considered very useful.

158. MENTHA VIRIDIS, Linn.—SPEARMINT.

**History.**—See *Mentha piperita*.

**Botany.** Gen. Char.—Calyx campanulate or tubular, 5-toothed, equal or somewhat 2-lipped, with the throat naked inside, or villous. Corolla with the tube inclosed, the limb campanulate, nearly equal, 4-cleft; the upper segment broader, nearly entire or emarginate. Stamens 4, equal, erect, distinct; filaments smooth, naked; anthers with two parallel cells. Style shortly bifid, with the lobes bearing stigmas at the points. Nucules dry, smooth (Bentham).

Sp. Char.—Stem erect, smooth. Leaves subsessile, ovate-lanceolate, nearly serrated, smooth; those under the flowers all bract-like, rather longer than the whorls; those last and the calyces hairy or smooth. Spike cylindric, loose. Whorls approximated, or the lowest or all of them distant. Teeth of the calyx linear subulate (Bentham).—Creeping-rooted.

Var. *M. angustifolia*, Bentham. Leaves of the branches with short petioles. Distinguished from *M. piperita* by the slender elongated spikes.

**Hab.**—Marshy places. Indigenous. A native of the milder parts of Europe; also of Africa and America. Perennial. Flowers in August. Selected for medicinal use when about to flower.

**Properties.**—The whole herb, called green-mint or spearmint (*herba menthae viridis*), is employed in medicine. It has a strong but peculiar odour, and an aromatic, bitter taste, followed by a sense of coldness when air is drawn into the mouth. Sesquichloride of iron communicates a green colour (*tannate of iron*) to the cold watery infusion.

**Composition.**—Its odour and aromatic qualities depend on volatile oil. It also contains tannic acid, resin (?), a bitter principle, and woody fibre.

**Physiological Effects.**—Aromatic, carminative, mildly stimulant and tonic. Feebler than Peppermint. Said, though without sufficient foundation, to check the secretion of milk, and to act as an emmenagogue.

**Uses.**—Employed as a salad and sweet herb. In medicine, it is principally used as a flavouring ingredient, and to alleviate or prevent colicky pains. The following are its official preparations, with their uses:—

1. **Infusum Menthae Viridis, D.; Infusion of Spearmint; Spearmint Tea.**—(Spearmint, dried and cut small, f2ij; Boiling Water Os.)—Stomachic and carminative. Used in irritable conditions of the stomach; but is ordinarily a vehicle for other remedies. Dose, 3f5ij to f3ij, or *ad libitum*.

2. **Oleum Menthae Viridis, L. E. D. [U. S.]; Oil of Spearmint.**—(Obtained by submitting the fresh herb to distillation with water.)—It is of a pale yellowish colour, but becomes reddish by age. It has the odour and taste of the plant, and is lighter than water; sp. gr. 0.914. It boils at 320° F.; and is composed, according to Dr. Kane, of **C**<sub>10</sub>H<sub>18</sub>O. The average produce of the essential oil is not more than 1-500th of the fresh herb. It is carminative and stimulant. Dose, gr. ij to gtt. v, rubbed with sugar and a little water.

3. **Spiritus Menthae Viridis, L.; Spirit of Spearmint.**—(Oil of Spearmint 3ij; Proof Spirit Cong. j. Dissolve.) Dose, 3f5ij to f3ij.—This preparation has no

---

advantages over, while it is much weaker than, the more simple and elegant preparation, the essence of spearmint of the shops.

4. ESSENTIA MENTHILE VIRIDIS, D.; Essence of Spearmint.—(Oil of Spearmint $\frac{f_{23}}{j}$; Stronger Spirit $\frac{f_{23}ix}{}$. Mix with agitation.)—It may be coloured green by spearmint or spinach leaves. Dose, gtt. x to gtt. xx, taken on sugar or in water. (This is the same as the Tinctura Olei Menthe Viridis (U. S. Pharm.), for which the formula is, Oil of Spearmint $\frac{f_{23}ij}$; Alcohol Oj. Dissolve the oil in the alcohol.)

5. AQUA MENTHILE VIRIDIS, L. E. D. [U. S.]; Spearmint Water.—(Spearmint, dried, $\frac{f_{23}}{j}$; Water Oj. Let a gallon distill. If the fresh herb be used, double the weight is to be employed. (The Edinburgh process is the same, except that $\frac{f_{23}ij}$ of Rectified Spirit is also used.) Or, Oil of Spearmint $\frac{f_{23}ij}$; Powdered Flint $\frac{f_{23}ij}{;}$ Distilled Water Cong. j. First diligently rub the oil with the flint, afterwards with the water, and strain the liquor, L.—Essence of Spearmint $\frac{f_{23}j}$; Distilled Water Cong. ss. Mix with agitation, and filter through paper, D. )—Spearmint water is usually made extemporaneously by suspending or dissolving a drachm of the oil in four pints of distilled water, by means of a drachm of rectified spirit and a lump of sugar [or by means of carbonate of magnesia, U. S.] (see vol. i. p. 304). Spearmint water is carminative and stomachic. It is commonly used as a vehicle for other medicines. Its dose is $\frac{f_{23}}{j}$ to $\frac{f_{23}ij}{;}$

159. MENTHA PIPERITA, Linn.—PEPPERMINT.

Sex. Syst. Didynamia, Gymnosperma. (Herba florens et exsiccata. Oleum ex herba florentae destillatun, L.—Herb; Volatile oil, E.—The herb, D.)

History.—The ancient Greeks employed in medicine a plant which they called Μαρμος, or Μυρον, and which, on account of its very agreeable odour, was also termed Ἡβοςομον, or the sweet-smelling herb. It was probably a species of Mentha; and, according to Fraas, was the Μ. piperita, Linn.; the Ἡβοςομον περιοδεως of the modern Greek Pharmacopoeia.

Peppermint came into use in England in the last century; at least Hill, in 1751, says that it “has lately got into great esteem;” and Geiger says it was introduced into Germany as a medicine, through the recommendations of the English, in the latter half of the last century.

Sp. Char.—Stem smooth. Leaves petiolated, ovate-oblong, acute, serrate, rounded-crenate at the base, smooth. Spikes lax, obtuse, short, interrupted at the base. Pedicels and calyces at the base smooth; teeth hispid (Bentham).—Creeping-rooted.

Var. Β. sub-hirsuta, Bentham; M. hirsuta, Smith. The nerves of the under surface of the leaves, as well as the petioles, hairy.

Hab.—Watery places. Indigenous. Extensively cultivated at Mitcham, in Surrey, from whence the London market is principally supplied. Found in various parts of Europe; also in Asia, Africa, and America.

Properties.—The whole herb (herba mentha piperita) is official. It has a peculiar aromatic odour, and a warm, burning bitter taste, followed by a sensation of coolness when air is drawn into the mouth. Sesquichloride of iron communicates a green colour (tannate of iron) to the cold infusion of peppermint.

Composition.—The principal constituents are volatile oil, resin, a bitter principle, tannic acid, and woody fibre.

Physiological Effects.—Peppermint is an aromatic or carminative, stimulant, and stomachic. It is the most agreeable and powerful of all the mints.

\[\text{Likewise, Hippocrates, De vicus rats. lib. ii. p. 339, ed. Fuss.; Dioscorides, lib. iii. cap. 36.}\]

\[\text{Likewise, Synop. Plant. Fl. Classicae, 1845.}\]

\[\text{Likewise, Hist. of the Mat. Med., p. 355.}\]

\[\text{Likewise, Handb. d. Pharm. Ed. iii. S. 1830.}\]
Uses.—It is employed in medicine for several purposes, but principally to expel flatus, to cover the unpleasant taste of other medicines, to relieve nausea, griping pain, and the flatulent colic of children. The following are the official preparations, with their uses:

1. OLEUM MENTHAE PIPERITAE, L. E. D.; Oil of Peppermint.—(Obtained by submitting the fresh herb to distillation with water.)—It is colourless, or nearly so, sometimes having a pale yellow or greenish tint, and becoming reddish by age. It has a penetrating odour like that of the plant, and a burning aromatic taste, followed by a sensation of cold. The vapour of it applied to the eye causes a feeling of coldness.

Oil of peppermint consists of two isomeric oils—one liquid, the other solid; the latter is called peppermint-camphor, or the stearoptene of oil of peppermint. Its composition is $\text{C}_{10}\text{H}_{18}\text{O}_2$. It is in colourless prisms, which have the odour and taste of peppermint, are almost insoluble in water, but readily soluble in alcohol and ether, and are fusible at 92° F. Under the influence of phosphoric acid, peppermint-camphor loses 2H$\text{O}$, and becomes a colourless liquid oil, called menthene $\text{C}_{10}\text{H}_{8}$.

I have met with three varieties of oil of peppermint:

a. English Oil of Peppermint.—This is the finest sort. Its sp. gr. is 0.902. It is obtained at Mitcham. In a warm, dry, and favourable season, the produce of oil, from a given quantity of the fresh herb, is double that which it yields in a wet and cold season. The largest produce is three drachms and a half of oil from two pounds of fresh peppermint, and the smallest about a drachm and a half from the same quantity. I was informed by a distiller at Mitcham, that twenty mats of the herb (each mat containing about 1 cwt.) yields about seven lbs. of oil.

b. American Oil of Peppermint.—In odour and flavour it is inferior to the preceding sort. It is said to be prepared from the dried plant gathered when in flower (Brande). It yields a considerable quantity of camphor.

c. China Oil of Peppermint. Po-loyo.—For a sample of this I am indebted to Dr. Christieon. It comes from Canton. It consists chiefly of peppermint-camphor, and forms a white crystalline solid even in summer.

Oil of peppermint is said to be adulterated with oil of rosemary; the odour would probably serve to distinguish the fraud.

Oil of peppermint is carminative and stimulant, and is used occasionally as an antispasmodic. It is taken on sugar, in doses of from 1/2 to 1 gtt. v.

2. SPIRITUS MENTHAE PIPERITAE, L.; Spiritus Menthae, E.; Spirit of Peppermint.—(Prepared with the Oil of Peppermint, in the same way as the Spiritus Menthae viridis, L., before described. The Edinburgh College prepares it thus: Peppermint, fresh, Ibiss; Proof Spirit Ovij. Macerate for two days in a covered vessel; add a pint and a half of water, and distil off seven pints.)—A solution of the oil of peppermint may with great propriety be substituted for the preparation of the Pharmacopoeias. The spirit of peppermint is given in doses of from $\frac{3}{8}$ to $\frac{3}{2}$ ij.

3. ESSENTIA MENTHAE PIPERITAE, D.; Essence of Peppermint.—(Oil of Peppermint $\text{f}_{\text{ij}}$; Stronger Spirit $\text{f}_{\text{ix}}$. Mix with agitation.)—[This is the Tr. Olei Menthae Piperitae, U. S. The Formula as for Tincture of Oil of Spearmint.] Some persons add peppermint or spinach leaves to communicate a green colour. The dose of this essence is from 1 gtt. xx to 1 gtt. xxx, on sugar.

4. AQUA MENTHAE PIPERITAE, L. E. D.—(Prepared with the herb or the oil of peppermint, in the same way as the Aqua Menthae viridis.)—Carminative and stimulant. Used to relieve flatulency, and as a vehicle for other medicines. Dose, $\frac{3}{2}$ to $\frac{3}{2}$ ij.

Besides the above, there are several popular preparations of peppermint extensively used.

a. Infusum Menthe piperiti (Peppermint Tea) is prepared in the same way as spearmint tea.
b. Eleuascarum Mentha piperita, Ph. Boer., is prepared by mixing $\frac{3}{3}$ of the whitest sugar, in powder, with gtt. xxiv of the oil of peppermint.

c. Rotule Mentha piperita (in plano convex masses, called peppermint drops)—in flattened cir-

1 Brande, Dist. of Mat. Med. p. 366.
cular disks, termed peppermint lozenges) should consist of sugar and oil of peppermint only, though flour is sometimes introduced. The liqueur sold at the spirit-shops as mint or peppermint is used as a cordial.

160. MENTHA PULEGIUM, Linn.—PEPPROYAL.

**Sec. Syst. Didynamia, Gymnosperma.**

(Herba flores recens et exsiccata. Oleum ex herba florente destillatum, L.—Herb, E. D.)

**History.** This plant was employed in medicine by the ancient Greeks and Romans. It is the ῥυξων of Hippocrates and Dioscorides, and the Pulegium of Pliny.

**Botany.** Gen. Char.—See Mentha viridis.

**Sp. Char.**—Stem very much branched, prostrate. Leaves petiolated, ovate. Whorls all remote, globose, many-flowered. Calyxes hispid, bilabiate, villous in the inside of the throat (Bentham).—Creeping-rooted.

**Hab.**—Wet commons and margins of brooks. Indigenous. A native of most parts of Europe, of the Caucasus, Chili, and Teneriffe.

**Properties.**—The herb with the flowers (herba seu summitates pulegii) is employed in medicine. It has a strong, but peculiar odour; a hot, aromatic, bitter taste, followed by a feeling of coolness in the mouth. Sesquichloride of iron causes a green colour (tannate of iron) with the cold infusion of pepproyal.

**Composition.**—Its principal constituents are volatile oil, a bitter matter, resin? tannic acid, and woody fibre.

**Physiological Effects.**—Its effects are analogous to the other mints. Emmenagogue and antispasmodic properties are ascribed to it by the public, and formerly by medical practitioners.

**Uses.**—A popular remedy for obstructed menstruation, hysterical complaints, and hooping-cough. Rarely employed by the professional man. The following are its official preparations, with their uses:—

1. OLEUM MENTHAE PULEGII, L. E. D.; Oleum Pulegii, offic.; Oil of Pennyroyal.—(Obtained by submitting the herb to distillation with water.)—It has a pale colour, a warm taste, and the peculiar odour of the herb. It boils at 395° F. Its sp. gr. is 0.925; and is composed, according to Dr. Kane, of C\textsubscript{10}H\textsubscript{18}O. The fresh herb yields from 1-120th to 1-100th of its weight of oil. It is stimulant and carminative, and is used, as an antispasmodic and emmenagogue, in doses of from gtt. iij to gtt. v, taken on sugar.

2. SPIRITUS MENTHAE PULEGII, L.; Spiritus Pulegii; Spirit of Pennyroyal.—(Prepared with Oil of Pennyroyal, as the Spiritus Menthae viridis.)—Usually prepared by dissolving the oil in spirit. Stimulant and carminative. Employed as an antispasmodic and carminative. Dose, f\textsubscript{5}zs to f\textsubscript{5}ij.

3. ENSENTIA MENTHAE PULEGII, D.; Essence of Pennyroyal.—(Oil of Pennyroyal f\textsubscript{5}j; Recified Spirit f\textsubscript{5}ix. Mix with agitation, D.)—May be given in doses of from gtt. x to gtt. xx.

4. AQUA MENTHAE PULEGII, L. E. D.; Aqua Pulegii, offic.; Pennyroyal Water.—(Prepared with the herb or oil, like Aqua Menthae viridis.)—Carminative and stomachic. Dose, f\textsubscript{5}ij to f\textsubscript{5}iij.

The liquid sold in the shops as Penroyal and Hysterical Water is prepared by adding f\textsubscript{3}zs of the compound spirit of bryony to Oos of pennyroyal water.

\footnotesize{1 P. 359, A. C. E. F.\footnotesize{2} Hist. Nat. lib. xx. cap. 54, ed. Vulp.\footnotesize{3} Lib. iii. cap. 36.\footnotesize{4} Brande, Dict. Mat. Med. p. 357.}
161. ORIGANUM VULGARE, Linn.—COMMON OR WILD MARJORAM.

**Sex. Syst.** Didynamia, Gymnosperma. (Herb. E. — Oleum ex herba.)

**History.**—Fraas¹ is of opinion that this plant is the ὑφαίνων μίλαν of Theophrastus,² the ἄγγελος of Dioscorides.³

**Botany.** Gen. Char. — Calyx ovate-campanulate, nearly 13-nerved, 5-toothed or 2-lipped, the upper lip entire or 3-toothed, the inferior lip 2-toothed, truncate, or altogether deficient, the calyx being then oboeompressed-flat. Tube of the corolla inclosed or exserted, the upper lip emarginate or slightly 2-eleft, the lower lip longer, spreading, 3-cleft. *Stamens* 4, ascending or straggling at the apex, or distant at the base; anthers with 6 distinct diverging or straggling cells. Lobes of the style acute, the posterior one usually shorter. Floral leaves bract-like. Flowers in spikes (Bentham).

**Sp. Char.** — Erect, villous. Leaves petiolate, broad-ovate, obtuse, subbaccate, broad-rounded at the base, green on both sides. Spikes oblong or cylindrical, clustered in corymbose panicles. Bracts (floral leaves) ovate, obtuse, coloured, (commonly glandless), half as long again as the calyx (Bentham).—Creeping-rooted. Flowers light purple.

**Hab.** — In bushy places, on a limestone and gravelly soil. Indigenous. A native of several parts of Europe; also of Asia. Flowers in July and August.

**Properties.** — The whole herb (herba origani) is officinal. It has a peculiar aromatic odour, and a warm pungent taste. Sesquichloride of iron produces a green colour (tannate of iron) with the cold infusion of origanum:

**Composition.** — Volatile oil, resin? tannic acid, a bitter principle, and woody fibre, are the principal constituents of this plant.

**Physiological Effects.** — Stimulant and carminative, like the other labiate plants.

**Uses.** — Principally employed to yield the volatile oil. The dried leaves have been used as a substitute for China tea.⁴ The infusion of origanum has been used in chronic cough, asthma, and amenorrhoea.

**Oleum Origani, E. [U. S.]; Oil of Common Marjoram.**—(Obtained by submitting the herb to distillation with common water.)—The average produce of essential oil from the herb is one pound from two hundred weight; but it varies exceedingly with the season and culture of the plant.⁵ According to Dr. Kane, its sp. gr. is 0.867, its boiling point 354° F.; and its composition C_{18}H_{20}O.

It is a powerful acrid and stimulant; and is applied to curious teeth by means of lint or cotton, to relieve toothache. Mixed with olive oil, it is frequently employed as a stimulatim liniment against alopecia or baldness, rheumatic or paralytic affections, sprains, bruises, &c.

The red volatile oil, usually sold in the shops as oleum origani or oil of thyme, is obtained from *Thymus vulgaris*, and is imported from the south of France (see *Thymus vulgaris*).

162. ORIGANUM MAJORANA, Linn.—SWEET OR KNOTTED MARJORAM.

**Majorana hortensis, Marn.**

**Sex. Syst.** Didynamia, Gymnosperma. (Herb.)

**History.** — Fraas⁶ is of opinion that the ἀμάξων of Theophrastus,⁷ the σάμψων of

---

¹ Synops. Plant. Fl. Classica, 1815.
² Lib. ii. cap. 34.
⁴ *Hist. Plant. lib. vi. cap. 2.
⁷ *Hist. Plant. lib. viii. cap. 7.*
of Dioscorides,¹ and the Amaracam or Samsuchum of Pliny,² are identical with our sweet marjoram.

BOTANY. Gen. Char.—See ante, p. 448.

Sp. Char.—Branches smoothish, racemose-paniculate. Leaves petiolate, oblong-ovate, obtuse, quite entire, on both sides hoary-tomentose. Spikelets oblong, on sessile crowded branchlets. Calyx nearly toothless, cleft anteriorly (Bentham).—Flowers purple or white.

Hab.—Africa and Asia. Cultivated in kitchen gardens.

Properties.—The whole plant (herba majorana) has a warm aromatic flavour, and a peculiar savoury smell. Its watery infusion is deepened in colour (tannate of iron) by sesquichloride of iron.

Composition.—By distillation the plant yields volatile oil. The other constituents are tannic acid, resin? bitter matter, and woody fibre.

Oil of Sweet Marjoram (Oleum Majorana) is pale yellow or brownish, with the strong odour and taste of marjoram.

Physiological Effects.—Tonic and mild stimulant.

Uses.—Principally employed as a sweet herb by the cook. Its powder is sometimes used, either alone or mixed with some other powder, as an errhine. Marjoram tea is occasionally employed as a popular remedy for nervous complaints.

163. THYME VULGARIS, Linn.—COMMON OR GARDEN THYME.

Sex. Syst. Didynamis, Gymnospermia.

(Thyme et Oleum.)

History.—The true Thyme, oμος of the ancients, is the Thymus capitatus, Hoffm. et Link. (Satureja capitata, Linn.)

Botany. Gen. Char.—Calyx ovate, 10—13-nerved, 2-lipped; upper lip 3-toothed, spreading; lower lip 2-cleft, with ciliate, subulate segments; throat villous inside. Corolla having the tube inclosed by the calyx or imbricated bracts, naked inside; limb sub-bilabiate; upper lip straight, emarginate, flattish; lower lip spreading, 3-cleft, with equal lobes, or the middle one largest. Stamens exerted, or rarely inclosed, straight, distant, nearly equal or didynamous, the lower 2 being the longest. Anthers with 2 parallel or at length diverging cells. Style about equally bifid at the apex, with subulate lobes (Bentham).

Sp. Char.—Erect or procumbent at the base. Leaves sessile, linear, or ovate-lanceolate, acute, with revolute edges, fascicled in the axils. Bracts (floral leaves) lanceolate, obtuse. Whorls loose, rather distant. Teeth of the upper lip of the calyx lanceolate; the segments of the lower lip subulate ciliated (Bentham).—Shrub much branched, ½ to 1 foot high, rather hoary with a short down. Flowers purplish.

Var. a. latifolius; Broad-leaved Garden Thyme.—Cultivated in gardens for culinary purposes.

Var. B. angustifolius; Narrow-leaved Garden Thyme.

A variegated variety is cultivated for ornament. Lemon Thyme, which is cultivated for culinary purposes, is T. Serpyllum, var. vulgaris, Bentham.

Hab.—South-West of Europe, in dry, arid, uncultivated places. Cultivated as a sweet herb in England.

Description.—The flowering-tops of garden thyme (herba et summilates thymi) are dried, and sold in the shops as one of the herbs used for culinary purposes. The odour is fragrant, and to most persons agreeable.

Composition.—Similar to that of Origanum vulgare. The odour and condimentary properties depend on volatile oil (oleum thymi).

Effects and Uses.—Similar to the other sweet herbs. Chiefly used by the

¹ Lib. iii. cap. 47.

VOL. II.—29
cooking for soups, stuffings, and sauces. In the South of France the herb is used for distillation, to yield the oil of thyme.

OLEUM THymi; Oil of Thyme.—At Milhau, Aujargues, Souvignargues, and near the village of Fontanes, as well as at several other places in the neighbourhood of Nismes, in the department of Gard in the South of France, this oil is largely distilled, and is imported into England and sold as oleum origani. Mr. Daniel Hanbury, who visited this district in the summer of 1849, tells me that the plant grows spontaneously in abundance on the arid, rocky, waste hills of that neighbourhood. The entire plants, whether in flower or not, are collected, and, either in the fresh or dried state, submitted to distillation with water. The oil, which is of a reddish-brown colour, is called red oil of thyme (huile rouge de thym), becomes much paler by redistillation, and is then called white oil of thyme (huile blanche de thym). The specimen of red oil of thyme obtained by Mr. D. Hanbury is identical with the oil sold as oleum origani in the London shops, all of which is imported. Specimens of the plant which yields the oil have been examined by Mr. Bentham, Dr. Lindley, and others; and by all have been pronounced undoubtedly Thymus vulgaris.

The medicinal properties and uses of oil of thyme are the same as those of the oleum origani, for which it is usually employed (see ante, p. 448).

164. MELISSA OFFICINALIS, Linn.—COMMON BALM.

Sex, Syst. Didynamia, Gymnospermia.
(Herba, E.)

History.—Both Smith5 and Sprengel6 consider this plant to be the melisposphila or melitassa of Dioscorides; but Fraas7 is of opinion that the Melissa altissima is the species referred to by Dioscorides.

Botany. Gen. Char.—Calyx tubular-campanulate, 13-ribbed, 2-lipped, the upper lip nearly flat, 3-toothed, the inferior lip bifid, the throat naked within. Tube of the corolla recurved-ascending, enlarged from above, naked within, limb 2-lipped, upper lip emarginate erect, lower ones spreading, 3-cleft, the lobes flat, the middle one entire or emarginate. Stamens 4, arching-converging; cells of the anthers at length straggling. Lobes of the style nearly equal, subulate. Nucules dry, smooth (Bentham).

Sp. Char.—Erect, branching. Leaves broad-ovate, crenate, truncate or cordate at the base; the floral ones nearly similar to the cauline ones. Whorls axillary, loose, 1-sided. Bracts (floral leaves) few, ovate. Corolla longer by half than the calyx (Bentham).

Hab.—South of France.

Properties.—The fresh herb (herba melisse) has a strong, peculiar odour, which is somewhat similar to that of lemons. By drying, this is, for the most part, lost. The taste is aromatic, bitter, and somewhat astringent. Sesquichloride of iron gives a greenish colour (tannate of iron) to the cold infusion.

Composition.—The principal constituents of balm are volatile oil, resin, bitter matter, gum, tannic acid, and woody fibre.8

Oil of Balm (Oleum Melissa) is pale yellow, and has the peculiar odour of balm. Its sp. gr. is 0.975. Oil of lemon is said to be frequently substituted for it.

Physiological Effects.—The effects of balm are similar to, though milder than, those of the labiate plants already described. The mildness of its operation arises from the small quantity of volatile oil which the plant contains.

1 The price at which the oil is sold by M. Sagnier, and other exporters at Nismes, is so low as to preclude its distillation in England.
3 Ibid. iii. cap. 118.
5 Hist. Rer. Herb. t. i. p. 100.
6 Synopsis Plantarum It. Classicæ, p. 192, 1815.
COMMON ROSEMARY:—HISTORY; BOTANY; PROPERTIES.

USES.—Balm tea is sometimes employed as a diaphoretic in fevers, as an exhilarating drink in hypochondriasis, and as an emmenagogue in amenorrhoea and chlorosis.

 Tribe III. Monardeae, Benth.

Stamens 2, straight or ascending; cells of the anthers oblong-linear, or solitary, or separated by the filiform connective (very rarely approximate in Perowskin).

165. ROSMARinus OFFICINALIs, Linn.—COMMON ROSEMARY.

SEX. Synt. Diandria, Monogynia. (Oleum e cuminia florente destillatum, L.—Tops, E. D.)

HISTORY.—The Λιβανοτίς στέφανωματικός, or Libanotis coronaria of Dioscorides, is supposed to be our official rosemary, which received its name, Λιβανοτίς (from Λιβανος, Thus), on account of its odour, and στέφανωματικός (στεφανωματικός, corona-rius), from its use in making garlands. Pliny calls it Rosmarinus. The flowers are termed anthos (from ἄνθος, a flower), signifying they are the flowers par excellence; just as we call cinchona the bark, and the inspissated juice of the poppy, opium (i. e. the juice).

BOTANY. GEN. CHAR. —Calyx ovate-campanulate, 2-lipped; the upper lip entire, the lower bifid, the throat naked within. Corolla with a protruding tube, smooth and not ringed in the inside, somewhat inflated in the throat; limb 2-lipped; lips nearly equal, the upper one erect and emarginate, the lower spreading, trifid, with the lateral lobes oblong, erect, somewhat twisted; the middle lobe very large, concave, and hanging down. No rudiments of the superior stamina; fertile (inferior) ones, 2, ascending, protruding; filaments inserted in the throat of the corolla, shortly-toothed near the base; anthers linear, subbilocular; the cells straggling, confluent, connate at the margin. Upper lobe of the style very short. Nucules dry, smooth (Benthem).

SP. CHAR. —The only species. —Leaves sessile, linear, revolute at the edge, hoary beneath. Calyx purplish. Corolla white or pale purplish-blue.

HAB. —South of Europe; also Asia Minor.

PROPERTIES.—The flowering-tops (cuminia rosmarini) are the officinal parts. They have a strong and remarkable odour, and a warm bitter taste.

COMPOSITION.—The peculiar odour and flavour of this plant depend on volatile oil. Besides this, the tops contain tannic acid, a bitter matter, resin and woody fibre.

PHYSIOLOGICAL EFFECTS.—Carminative and mildly stimulant, analogous to the other labiate plants.

USES.—Rarely employed medicinally. Infusion of Rosemary (rosemary tea) is sometimes used as a substitute for ordinary tea by hypochondriacal persons. The admired flavour of Narbonne honey depends on the bees collecting this substance from rosemary plants, which abound in the neighbourhood of Narbonne: hence sprigs of rosemary are sometimes added to the honey of other places, in order to imitate the flavour of Narbonne honey.

1. OLEUM ROSMARINI, L. E. D. [U. S.]; Oleum Anthes, offic.; Oil of Rosemary.— (Prepared by submitting the rosemary tops to distillation with water.)—This oil was first procured by Raymond Lully. It is transparent and colourless, with the odour of rosemary, and a hot, aromatic taste. Its sp. gr. is 0.897; and it boils at 365° F. It consists, according to Dr. Kane, of C<sub>10</sub>H<sub>18</sub>O<sub>2</sub>. One pound of the fresh herb yields about one drachm of the oil. The Arabian name signifies "royal crown."
is not unfrequently used externally, in conjunction with other substances, as a stimulating liniment; for example, in alopecia, or baldness, and also as a perfume. Dose, gtt. 1j to gtt. v.

2. SPIRITUS ROSMARINI, L. E. D. [U. S.]; Spirit of Rosemary.—(Oil of Rosemary 3ij; Rectified Spirit Cong. j. Dissolve, L.—The Edinburgh College submits the tops, ibijj, to distillation with a gallon of Rectified Spirit, so as to obtain seven pints of the distilled spirit.)—It is usually prepared merely by dissolving the oil in spirit, distillation being superfluous. Seldom employed internally. Its principal use is as an odoriferous adjunct to lotions and liniments. It is a constituent of the Linimentum Saponis (see vol. i. p. 552), and Tinctura Lavandulae composita (see ante, p. 442).

3. ESSENTIA ROSMARINI, D.; Essence of Rosemary.—(Oil of Rosemary f3iij; Rectified Spirit f3ix. Mix with agitation.)—Its uses are the same as those of the spirit just noticed.

4. AQUA HUNGARICA; Aqua Rosmarini seu Authoris composita; Hungary Water.—Various formulae for the preparation of this perfume have been given. The following is from the Pharm. Wurttem and Bavar.: Take of fresh Rosemary, in blossom, Biv; fresh Sage, in blossom, 3ij; Zingiber 3ij. Cut into pieces, and add Rectified Spirit 5ij; Common Water Oij. Let eleven pints distil by a gentle heat. A hermit is said to have given the formula for the preparation of this perfume to a queen of Hungary; whence this water has been called the Queen of Hungary’s Water (Aqua Regina Hungaria).1 Hungary water is frequently imitated by mixing Spirit of Lavender f5ij with Spirit of Rosemary f5iv.—This liquid is employed principally as a perfume for the toilet; also as an excitant and restorative in painting. Externally, it is used as a stimulating liniment.

TRIBE IV. STACHYDEAE, Benth.

Stamens 4, ascending under the helmet (which is usually concave).

166. MARRUBIUM VULGARE, Linn.—WHITE HOREHOUND.

Sex. Syst. Didynamia, Gymnospermae.

(Herba.)

HISTORY.—This is the plant which is called пасов by Hippocrates, Theophrastus, and Dioscorides;2 and Marrubium by Pliny.3

BOTANY. Gen. Char.—Calyx tubular, 5—10-nerved, equal; teeth 5—10, acute, somewhat spinous, nearly equal, erect, or often spreading at maturity. Corolla with an inclosed tube, which is naked inside, or somewhat annulated, and a 2-lipped limb; the upper lip erect, flat-tish or concave, entire or shortly bifid; the lower lip trifid, spreading, the middle lobe the broadest, often emarginate. Stamens inclosed within the tube of the corolla; anthers with 2 straggling, somewhat confluent cells, all nearly alike. Style bifid at the apex, with short obtuse lobes. Nucules obtuse, not truncate at the apex (Bentham).

Sp. Char.—Branches white-woolly. Leaves ovate or rounded, softly villous, greenish or white-woolly beneath, crenate. Whorls many-flowered. Calyx villose, woolly, with 10 subulate, recurved-spreading or woolly teeth. Corolla with an oblong helmet, bifid at the point (Bentham). Flowers white.

Hab.—Dry waste grounds. Indigenous. Grows in most parts of Europe; also in Asia and America. Flowers in July.

PROPERTIES.—The whole herb (herba marrubii) is used in medicine. It has an aromatic odour, and a bitter taste. Sesquichloride of iron communicates an olive-green tint (tannate of iron) to the cold watery infusion.

1 For the history of Hungary water, see Beckmann’s History of Inventions, translated by Wm. Johnston, vol. ii. p. 107, 1791
2 Lib. iii. cap. 119.
Great Mullein or High Taper:—History; Botany. 453

Composition.—Its bitterness depends on extractive; its aromatic properties on volatile oil. Besides these principles it contains resin, tannic acid, bitter matter, and woody fibre.

Physiological Effects.—Horehound is tonic, mildly stimulant, and, in large doses, laxative. Taken in the form of infusion, it promotes the secretions of the skin and kidneys. It was formerly supposed to possess emmenagogue properties.

Uses.—It is rarely employed by medical practitioners. As a domestic remedy it is used in chronic pulmonary complaints, especially catarh. It was formerly given in uterine and hepatic affections.

Administration.—Horehound tea (prepared by infusing an ounce of the herb in a pint of boiling water) is taken in the dose of a wineglassful. Syrup of horehound (prepared with the infusion and sugar) is a popular remedy, and is kept in the shops. Candied horehound ought to be made of the same ingredients.

Ballota nigra, Linn., or Stinking Black Horehound, possesses similar properties to the Marrubium vulgare.

Characters.—Flowers hermaphrodite, usually irregular. Calyx free, persistent, 5—4-merous. Corolla gamopetalous (monopetalous), hypogynous, pentameros or (the upper petals being united) tetramerous, very rarely 6—7-merous, or 2-lobed, the lobes being united; bilabiately or irregularly imbricated, very rarely (in a few didynamous or diandrous genera) plaited in resiliation. Stamens inserted on the corolla, alternate with its lobes; the upper stamen usually, and the 2 anterior or posterior ones sometimes, sterile or deficient; anthers 2-celled, or by growing together or by half disappearing, 1-celled; the cells dehiscing by a longitudinal slit. Ovary free, 2-celled; ovules in each cell many (very rarely 2 together), inserted on the dissepiment near the axis, anatropous or amphitropous. Style simple, or very shortly bifid, at the apex; the stigmatic part either very thin, or incassate, entire, or 2-lobed. Fruit capsular, dehiscing, variously or rarely bacinate. Placenta 4, separatile by dehiscence, or united variously with each other, with the edges of the valves, or with the central column. Seeds albuminous, indefinite with the radicle towards the basilar hilum, or few and definite with a more or less lateral hilum, and the radicle towards the apex of the fruit; embryo straight, or rarely curved.—Herbs, undershrubs, or rarely shrubs. Leaves opposite, whorled, or alternate. Stipules commonly absent. Inflorescence centrifugal or centripetal. Bracts 2, opposite, or solitary; bractlets none, or 1 or 2, alternate, or nearly opposite (Bentham).

Properties.—Juice watery, frequently bitter, astringent or narcotic.

167. Verbascum Thapsus, Linn.—Great Mullein or High Taper.

Sex. Syst. Pentandria, Monogynia. (Folli.)

History.—This plant is, according to both Smith and Frasa, the φίλιας λευκής δέντρων of Dioscorides.

Botany. Gen. Char.—Calyx deeply 5 cleft or 5-partite, rarely 3-toothed. Corolla flat, expanded, or rotate, rarely concave; the segments scarcely unequal. Stamens 5; the filaments either the 3 posterior ones, or all woolly or bearded, rarely (abnormally) naked. Style compressed-dilated at the apex, rather thick. Capsula globose, ovoid or oblong, dehiscing (Bentham).

Sp. Char.—Nearly simple, densely yellowish or whitish, tomentose. Radical leaves oblong, crenulate; those of the stem decurrent, winged, acuminate. Raceme dense, or interrupted at the base. Throat of the corolla concave. Anthers inferior, shortly decurrent (Bentham).—Corolla golden-yellow; stamens red; stigma green.

Hab.—Indigenous; on banks and waste ground. Biennial. Flowers in July and August.

Description.—The leaves (folia verbasci) have a mucilaginous, bitterish taste, and a very slight colour. They communicate their virtues to water.

Composition.—Morin analyzed the flowers of Verbascum Thapsus, and obtained a yellow

Vegetable oil, a fatty acid, free malaic and phosphoric acids, malate and phosphate of lime, acetate of potash, uncrystallizable sugar, gum, chlorophyll, and yellow resinous colouring matter.

Physiological Effects.—Emollient, demulcent, and supposed to be feebly narcotic. Fishes are stupefied by the seeds of Verbascum.¹

Uses.—In the form of decoction (prepared of $\frac{3}{4}$ of the leaves and $\frac{1}{2}$ of water) mullein has been used in caurals and diarrhœas; the dose is $\frac{2}{3}$ of a glass. Dr. Home² found it serviceable in the latter complaint only. Fomentations and cataplasms made of great mullein have been used as applications to hemorrhoidal tumours and indurated glands.

168. SCROPHULARIA NODOSA, Linn.—KNOTTY-ROOTED FIGWORT.

Sex. Syst. Didynamis, Angiosperma.

(Forla.)

History.—The earliest notice of this plant occurs in the work of Brunfels.³

Botany. Gen. Char.—Calyx deeply 5-cleft or 5-partite. Tube of the corolla ventricose, globular, or oblong; segments of the limb short, the 4 upper ones erect, the lower one spreading, 2 upper ones usually longest. Stamens diynamous, definite, cells of the anthers united transversely to one; the rudiment of a fifth sterile stamen at the apex of the squamiform tube often present: Capsule usually acute, the valves entire or bifid at the apex. Seeds ovoid, rugose (Bentham).

Sp. Char.—Smooth. Stem angular. Leaves ovate, ovate oblong, or the upper ones lanceolate, acute, serrate or somewhat incised, broadly cordate or rounded at the base. Thyrsus oblong, beardless, or scarcely clothed with leaves at the base. Cymes pendunculate, loosely many-flowered. Segments of the calyx broadly ovate, obtuse, with the margin very narrow. The sterile anther broadly orbiculate (Bentham).—Corolla dull green, with a vivid purple lip.

Hab.—Indigenous; hedges, woods, and thickets. Perennial. Flowers in July.

Description.—The fresh leaves (folia scrophulariae nodose) have, when bruised, a fetid odour; their taste is bitter, and somewhat acid. Water extracts the virtues of the plant; the infusion is darkened by the sesquichloride of iron, but is unchanged by tincture of nux-galis.

Composition.—The whole plant (root and herb) was analyzed in 1830 by Grandson.⁴ He obtained brown bitter resin 0.31, extractive with gum 4.84, extractive boiling the odour of benzoic acid 0.88, chlorophylle 1.58, starch 0.23, greenish fucula 0.18, mucilage 0.27, inulin 0.16, malic acid 0.15, pectic acid 0.15, acetic acid 0.13, woody fibre 19.50, water 70.31, sulphate and carbonate of potash 0.59, aluminia 0.20, oxalate and carbonate of lime 0.46, magnesia, 0.26, silica 0.07, odorous material and loss 0.31.

Physiological Effects.—But little known. Judging from their taste, the leaves possess acrid properties. When swallowed, they occasion vomiting and purging. They are said to be diuretic and narcotic.

Uses.—Rarely employed. In the form of a fomentation, the leaves are sometimes applied to piles and other painful tumours. The ointment is used in skin diseases. The tuberous root was formerly esteemed in scorfula.⁵

unguentum scrophulariae; Ointment of Scrophularia.—(Fresh leaves of Scrophularia nodosa, Prepared Hog's Lard, of each $\frac{1}{2}$, Prepared Mutton Suet $\frac{1}{2}$). Boil the leaves in the fat until they become crisp, then strain by expression.)—Recommended by Dr. W. Stokes⁶ for the cure of a disease of children, commonly termed burn-holes, and which he calls Pemphigus gangrenosus [Rupia escharotica?]. It has also been used in tinea capitis, impetigo, and other cutaneous affections.⁷

169. Gratiola Officinalis, Linn.—Officinal Hedge Hyssop.

Sex. Syst. Diandria, Monogynia.

(Herba.)

A perennial plant, native of the South of Europe. Cultivated in England, and formerly contained in the British Pharmacopoeia. The herb (herba gratiola) is cathartic, diuretic, and emetic, acting in large doses as an acrid poison. It has been used in visceral obstructions, liver affections, dropsies, scorfula, and venereal diseases. Dose of the powder gr. xv to $\frac{2}{3}$ of the infusion (prepared with $\frac{3}{4}$ of the dried herb and $\frac{2}{3}$ of boiling water), $\frac{2}{3}$ to $\frac{3}{4}$, three times a day.⁸

170. DIGITALIS PURPUREA, Linn.—PURPLE FOXGLOVE.

Sex. Syst. Didynamia, Angiospernia.

(Herba agrestis Folium caulinae recens et exsiccatum, L.—Leaves, E. D.)

History.—It appears very improbable that the ancients should have overlooked so common and elegant a plant as foxglove; yet in none of their writings can we find any plant whose description precisely answers to the one now under examination. Fabricius Columna thought that it was the Ἐφύριον of Dioscorides, but the description of the latter does not at all agree with foxglove. The Νορμανδία of the same writer has also been referred to, but with little more probability of correctness. The term Foxglove, occurs in a MS., Glossarium Ælfrici, probably written before the Norman Conquest (A. D. 1066), and in a MS. Saxon translation of L.Apulius; both of which are among the Cottonian manuscripts in the British Museum. Fuchs is usually regarded as the earliest botanist who mentions this plant, which he named Digitalis (from Fingerhut, a finger-stall, on account of the blossoms resembling the finger of a glove). Fuchsius states that, until he gave it this appellation, the plant had no Greek or Latin name.

Botany. Gen. Char.—Calyx 5-partite, imbricate. Corolla declinate; tube ventricose or campanulate, frequently constricted above the base; upper segment of the limb short, broad, emarginate or bident, spreading, the external lateral ones narrower, the lowest one longer than the others, extended. Stamens 4, didynamous, ascending, shorter than the corolla, and frequently inclosed within the tube; anthers approximated in pairs, their cells diverging and confluent. Style briefly bilobed at the apex; the lobes stigmatic within. Capsule ovate, 2-valved, with septicidal dehiscence; the valves entire, curved inwards at the margins, half exposing the placental column. Seeds numerous, minute, oblong, somewhat angular (Bentham).

Sp. Char.—Leaves ovate-lanceolate or oblong, crenate, rugose; the under surface or both surfaces, as well as the stem, tomentose or woolly. Raceme long, lax. Segments of the calyx ovate or oblong. Corolla enlarged above, campanulate; its segments obverse, shorter than broad, the lower one longer than the lateral ones. Herbaceous. Root of numerous long and slender fibres; biennial. Stem erect, 3 or 4 feet high, commonly simple, roundish, with several slight angles, downy. Leaves alternate, downy, veiny, of a dull green; tapering at the base into winged foot-stalks; lower ones largest. Raceme terminal, erect, one-sided, simple, of numerous, large, pendulous, odourless flowers. Corolla crimson, elegantly marked with eye-like spots, as well as hairy, within.

Var. albiflora.—A variety with white flowers, spotted with shades of cream-colour or pearl, is met with in gardens; it remains tolerably constant from seed.

Hab.—Indigenous; in pastures and about hedges or banks, on a gravelly or sandy soil.

Description.—The official parts of the leaves and seeds; the latter, however, are rarely employed. As some doubts have been expressed as to the equal activity of cultivated specimens, wild or native plants are to be preferred.

1. Foxglove leaves (folia digitalis).—The leaves should be gathered when the plant is in the greatest perfection—that is, just before or during the period of in fluorescence; and those are to be preferred which are full-grown and fresh. As the petioles possess less activity than the laminae or expanded portions of the leaves, they ought to be rejected. Dr. Withering directs the leaves to be dried either in the sunshine, or in a tin pan or pewter dish before the fire; but the more

6 Account of the Foxglove, p. 181, 1755.
The first year's leaves are frequently more tapering than those of the second year's growth; but this character is not much to be relied on; and, therefore, to avoid the substitution, the best and safest plan is to purchase the fresh leaves at the proper season—namely, just before or at the period of inflorescence (which is from the middle of June to the end of July).

The leaves of Inula Conyza, De Cand., or Ploughman's Spikenard, closely resemble those of Foxglove; but, when rubbed, are readily distinguished by their odour, which, by some, is called aromatic, by others fetid. Moreover, they are rougher to the touch, and are less divided on the edge.

Subsessile or shortly petiolate, ovate-lanceolate or oblong, narrow at the base, crenate, rugous and veined, tomentose beneath or on both sides.

It is to be gathered before the terminal flowers have unfolded. The petiole and midrib being removed, dry the lamina. (Pharm. Loud.)

2. **Foxglove seeds (semina digitalis).**—The seeds of the foxglove are small, roundish, and of a grayish-brown colour.

**Composition.**—Purple foxglove has been the subject of repeated chemical examination, but, until very recently, with no satisfactory results. Memoirs on its composition, or on its active principle, have been published by Destouches,\(^5\) Bidault de Villiers,\(^6\) Rein and Haase,\(^7\) Le Royer,\(^8\) Dulong d'Astafort,\(^9\) Meylink,\(^2\) Welding,\(^3\) Radig,\(^4\) Brault and Poggiale,\(^5\) Lancelot,\(^6\) Trommsdorff,\(^7\) Homolle,\(^8\) Nativelle,\(^9\) and by Morin.\(^10\) Homolle's memoir gained the prize offered by the Société de Pharmacie of Paris for the isolation of the active principle.

Morin found a peculiar volatile acid (antirrhinic acid), and a peculiar non-volatile acid (digitalic acid).

1. **Digitaline; Bitter Principle of Foxglove; Pierin.—** Homolle's process for obtaining digitaline, as simplified by M. Ossian Henry, is as follows: Digest 2 lbs. of carefully dried and powdered foxglove leaves with rectified spirit; and express the tincture strongly in a press. Draw off the spirit in a still, and treat the residual extract with half a pint of water acidulated with about two drachms of acetic acid. Digest with a gentle heat, add some animal charcoal, and filter. Dilute the filtered liquor with water, partly neutralize with ammonia, and add a fresh-made strong infusion of nutgalls; by this means tannate of digitaline is precipitated. Wash the precipitate with water, mix it with a little alcohol, and carefully rub it with finely powdered litharge. Expose the mixture to a gentle heat, digest with alcohol, decolorize the tincture by animal charcoal, and draw off the alcohol by a gentle heat. The residual extract is then to be treated with sulphurec ether, which takes up some foreign matters and leaves the digitaline. From 1 kilogramme (about 2 lbs. 6 oz. troy) of the leaves, O. Henry obtained from 140 to 150 grs. of digitaline.

Digitaline is white, inodorous, difficultly crystallizable, and usually occurs in porous mammillated masses, or in small scales. It is intensely bitter when in solution, and excites violent sneezing when it is pulverized. It is soluble in about 2000 parts of water, is very soluble in alcohol, but almost insoluble in ether. It does not contain nitrogen; nor does it neutralize acids. Concentrated sulphuric acid blackens it, and then dissolves it, forming a blackish-brown solution, which, in a few days, becomes successively reddish-brown, smoky amethyst, pure amethyst, and ultimately a beautiful crimson. If during this time a small quantity of water be added, a limpid, beautiful green solution is obtained. In concentrated and colourless hydrochloric acid digitaline dissolves, forming a solution, which passes from yellow to a fine green. This reaction Homolle considers to be sufficiently delicate for medico-legal researches.

The effects of digitaline on both animals and the human subject have been examined by Homolle, and by Boucharlat and Sandras. From their experiments, it appears that its effects are similar to those of the plant; but that it is at least 100 times as powerful as the powder of the dried plant. In the human subject, doses of from 2 to 6 milligrammes (from about 1-32d to 1-11th of an English grain) diminished the frequency of the pulse, and caused nausea, vomiting, griping, purging, and increased secretion of urine.

Digitaline has been employed in medicine, as a substitute for the plant, in doses of from 1-50th to 1-30th of a grain. It may be administered in substance in the form of pills, or dissolved in alcohol and given in the form of mixture or syrup. But the difficulty of adjusting these small doses, as well as the uncertainty of the purity and activity of the remedy, are great drawbacks to its use.

2. **Scaptin.—** Radig has applied the term scaptin to a brown, almost tasteless extractive, which leaves an acid sensation in the throat.

3. **Empyreumatic Oil of Foxglove (Pyrodigitaline).—** By the destructive distillation of the dried leaves of foxglove, Dr. Morrie obtained a coloured, disagreeable, empyreumatic oil, which was semi-solid at 60° F., and soluble in boiling alcohol and ether; the solution, on cooling, fell a flocculent precipitate composed of two substances; one crystalline, the other globular. Given to a rabbit, it caused paralysis of the hind legs, convulsions, laborious and rapid breathing, and accelerated action of the heart. It does not contain the sedative principle of foxglove.

**Chemical Characteristics.**—Sequechloride of iron causes a dark precipitate (tannate-pallate of iron) with decoction of foxglove leaves, as well as with the tincture diluted with water. A solution of gelatine, added to the decoction, causes, after some time, a scanty precipitate (tannate of gelatine). Tincture of nutgalls

---

3. *Annuaire de Thérapeutique pour 1845, p. 60.*
has scarcely any effect (perhaps a slight turbidity) when added to the decoction or to the tincture diluted with water.

(By the action of sulphuric or hydrochloric acid on the tincture or decoction of foxglove, I have not been able to detect the presence of digitaline.)

**Physiological Effects.**

a. *On Vegetables.*—Marret\(^1\) found that a solution of the watery extract of foxglove killed a haricot plant (*Phaseolus vulgaris*) in twenty-four hours.

b. *On Animals generally.*—The effects of foxglove have been tried on dogs,\(^2\) horses, rabbits,\(^3\) turkeys,\(^4\) the domestic fowl, and frogs; and on all it has been found to act as a poison. One drachm of the powder may be given to horses as a sedative in inflammation.\(^5\) Two ounces have produced death in twelve hours.\(^6\) According to the experience of Orfila, the first symptoms of poisoning observed in [carnivorous] animals is vomiting. The influence of the poison over the heart does not appear to be uniform; for in some cases he found the pulsations of this viscus unaltered, in others accelerated, while occasionally they were retarded. In the horse killed by two ounces of foxglove, the pulse was 130 per minute, a short time before death (Moiroud)—the standard pulse of the horse being 40 or 42 per minute. The cerebro-spinal symptoms observed in animals, are diminished muscular power, convulsive movements, tremors, and insensibility. The powder acts as a local irritant, giving rise to inflammation of parts to which it is applied (Orfila).

g. *On Man.*—We may, for convenience, establish three degrees of the operation of foxglove.

In the first degree, or that produced by small and repeated doses, foxglove sometimes affects what are termed the organic functions, without disordering the animal or cerebro-spinal functions. Thus we sometimes have the stomach disordered, the pulse altered in frequency, and sometimes also in fulness and regularity, and the secretion of urine increased, without any other marked symptoms. The order in which the symptoms just mentioned occur is not uniform; sometimes the diuresis, at others nausea, and occasionally the affection of the circulation, being the first obvious effect.

The influence of foxglove over the circulation is not at all constant. In some cases the frequency of the pulse is augmented, in others decreased, while in some it is unaffected. Lastly, in a considerable number of instances, the pulse becomes irregular or intermittent under the use of foxglove.\(^7\) A few drops of the tincture will, in some cases, reduce the frequency of the pulse, and render it irregular and intermittent, while in other instances much larger doses may be taken without any obvious effect on it. Dr. Withering\(^8\) mentions one case in which the pulse fell to 40; and I have several times seen it reduced to 50. In some cases the slowness of the pulse is preceded by an increased activity of the vascular system. From Sandras's reports\(^9\) this would appear to occur more frequently after small than large doses of foxglove. Dr. Sanders,\(^10\) indeed, asserts that foxglove invariably excites the pulse, and refers to an experience of 2000 cases in proof. He says, that he has seen the pulse rise from 70 to 120 under the use of foxglove, and at the end of twenty-four hours, or sooner, fall with greater or less rapidity to forty, or even below this. But an experience of the use of foxglove, in only twenty cases, will, I believe, convince most persons that Dr. Sanders has fallen into an error in the sweeping assertion which he has made. A great deal, however, depends on the position of the patient. If it be desired to reduce the frequency of the pulse, the patient should be kept in a recumbent posture. The important influence of posture was first pointed out, I believe, by Dr. Baildon.\(^11\) His own pulse, which had been reduced by this plant from 110 to 40 beats per minute while he was in the recum-

bent position, rose to 70 when he sat up, and to 100 when he stood. We have a ready explanation of this fact. In a state of health, the pulsations of the heart are more frequent (usually to the extent of five or six in the minute) in the erect than in the horizontal position; and it is very obvious that greater force is required to carry on the circulation in the former than in the latter, since, in the erect position, the heart and arteries have to send blood to the head against gravity. Now, the power of the heart being enfeebled by foxglove, when a demand is made on this viscus for an increase in the force of contractions by the change from the recumbent to the standing attitude, it endeavours to make up for its diminished force by an increase in the frequency of its contractions. I need scarcely add, that the sudden change of position in those who are much under the influence of this medicine, is attended with great danger, and in several instances has proved fatal; for, in consequence of the heart not having sufficient power to propel the blood to the head against gravity, fatal syncope has been the result. The influence of digitalis over the pulse is more marked in some individuals or cases than in others; thus the reduction of the frequency of the pulse is in general more readily induced in weak and debilitated constitutions, than in robust and plethoric ones. Occasionally, no obvious effect on the number, force, or regularity of the pulse is produced, though the foxglove may be given to an extent sufficient to excite vomiting and cerebral disorder. Shroek experienced, from two grains of foxglove, nausea, headache, small, soft, and quick pulse, dryness of the gums and throat, giddiness, weakness of limbs, and increased secretion of saliva. Some hours after, he observed sparks before the eyes, his vision became dim, and he experienced a sensation of pressure on the eyeballs.

A most important fact connected with the repeated uses of small doses of it, is the cumulative effect sometimes observed. It has not unfrequently happened that, in consequence of the continued use of small doses of this medicine, very dangerous symptoms, in some cases terminating in death, have occurred. The most prominent of these were great depression of the vascular system, giddiness, want of sleep, convulsions, and sometimes nausea and vomiting. A knowledge of its occasional occurrence impresses us with the necessity of exercising great caution in the use of this remedy, particularly with respect to the continuance of its administration and increase of dose; and it shows that, after the constitutional effect has become obvious, it is prudent to suspend from time to time the exhibition of the remedy, in order to guard against the effects of this alarming accumulation. I may add, however, that I have used it, and seen others employ it, most extensively, and in full doses, and have rarely seen any dangerous consequences; and I believe, therefore, the effects of accumulation to be much less frequent than the statements of authors of repute would lead us to expect. The experience of Dr. Holland is to the same effect. "Though employing the medicine somewhat largely in practice," he observes, "I do not recollect a case in which I have seen any injurious consequences from this cause."

The diuretic operation for which we employ foxglove is very inconstant. Dr. Withering stated that this medicine more frequently succeeds as a diuretic than any other; and that if it fail, there is but little chance of any other remedy succeeding. My experience, however, is not in accordance with Dr. Withering's. I have frequently seen foxglove fail in exciting diuresis, and have often found the infusion of common broom (Cytisus scoparius) subsequently succeed. It has been asserted by some, that the diuretic effect of foxglove was only observed in dropsical cases, and that it, therefore, depended on the stimulus given to the absorbent vessels, and not to any direct influence exerted over the kidneys; but the statement is not true,

---

3 See the cases published by Dr. Withering, op. cit.; also a fatal case recorded by Dr. Blackall, On Dropsy, p. 175, 4th ed.
since foxglove is sometimes found acting as a diuretic even in health. In some cases the bladder has appeared more irritable than usual, the patient having a frequent desire to pass his urine.

An increased flow of saliva is an occasional consequence of the continued use of moderate doses of foxglove. Dr. Withering first noticed this effect. Dr. Barton has also seen it produced from ordinary doses.

2. The second degree of operation of digitalis, or that ordinarily resulting from the use of too large or too long-continued doses, is manifested by the disordered condition of the alimentary canal, of the circulating organs, and of the cerebrospinal system. The more ordinary symptoms are nausea or actual vomiting, slow and often irregular pulse, coldness of the extremities, syncope, or tendency to it, giddiness, and confusion of vision. Sometimes the sickness is attended with purging, or even with diuresis; at other times the patient is neither vomited nor purged; and the principal disorder of system is observed in the altered condition of the nervous and vascular organs. Externals objects appear of a green or yellow colour; the patient fancies there is a mist, or sparks, before his eyes; a sensation of weight, pain, or throbbing of the head, especially in the frontal region, is experienced; giddiness, weakness of the limbs, loss of sleep, occasionally stupor or delirium, and even convulsions, may also be present. The pulse becomes feeble, sometimes frequent, sometimes slow; there may be actual syncope, or only a tendency to it, and profuse cold sweats. Salivation is sometimes produced by poisonous doses of foxglove. It was observed in a case narrated by Dr. Henry, and has been known to last three weeks.

The quantity of digitalis that may be given to a patient without destroying life, is much greater than is ordinarily imagined. In one instance I saw twenty drops of the tincture given to an infant labouring under hydrocephalus, three times daily for a fortnight, at the end of which time the little patient was completely recovered, without one untoward symptom. I have frequently given a drachm of the tincture (of the best quality) three times daily to an adult, for a fortnight, without observing any marked effect. I know that some practitioners employ it in much larger doses (as an ounce or half an ounce of the tincture), with much less effect than might be imagined. The following communication on this subject, from my friend Dr. Clutterbuck, illustrates this point: "My first information on this subject was derived from an intelligent pupil, who had been an assistant to Mr. King, a highly respectable practitioner at Saxmundham, in Suffolk, who on a subsequent occasion, personally confirmed the statement. This gentleman assured me, that he had been for many years in the habit of administering the tincture of digitalis, to the extent of from half an ounce to an ounce at the time, not only with safety, but with the most decided advantage, as a remedy for acute inflammation—not, however, to the exclusion of bloodletting, which, on the contrary, he previously uses with considerable freedom. To adults he often gives an ounce of the tincture (seldom less than half an ounce), and awaits the result of twenty-four hours, when, if he does not find the pulse subdued, or rendered irregular by it, he repeats the dose; and this, he says, seldom fails to lower the pulse in the degree wished for; and when this is the case, the disease rarely fails to give way, provided it has not gone the length of producing disorganization of the part. He has given as much as two drachms to a child of nine months. Sometimes vomiting quickly follows these large doses of the digitalis, but never any dangerous symptom, as far as his observation has gone, which has been very extensive. In less acute cases he sometimes gives smaller doses, as thirty drops, several times in a day.

Such is the account I received from Mr. King himself, and which was confirmed by his assistant, who prepared his medicines. I do not see any ground for questioning the faithfulness of the report. I have myself exhibited the tincture to the

4 Rust's Magazin. xxv. p. 678.
extent of half an ounce (never more), in not more than two or three instances (cases of fever and pneumonia). To my surprise, there was no striking effect produced by it; but I did not venture to repeat the dose. In numerous instances I have given two drachms; still more frequently one drachm; but not oftener than once in twenty-four hours, and not beyond a second or third time. Two or three exhibitions of this kind I have generally observed to be followed by slowness and irregularity of pulse, when I have immediately desisted." Dr. T. Williams\(^1\) states, that a man, in a state of intoxication, took two ounces of tincture of foxglove, in two doses, in quick succession, without the slightest inconvenience.

3. The third degree of the operation of foxglove, or that resulting from the use of fatal doses, is characterized usually by vomiting, purging, and gripping pain in the bowels; slow, feeble, and irregular pulse, great faintness, and cold sweats; disordered vision; at first giddiness, extreme dopathy; afterwards insensibility and convulsions, with dilated insensitive pupils.

If we compare the effects of foxglove with those of other medicinal agents, we find they approximate more closely to those of tobacco than of any other cerebro-spinant. These two agents especially agree in their power of enfeebling the action of the heart and arteries (see vol. i. p. 258). Green tea agrees with foxglove in its property of preventing sleep (see vol. i. p. 247). Considered as a diuretic, foxglove is, in some respects, comparable with squills. I have already pointed out the peculiarities attending the operation of each of these.

Uses.—We employ foxglove for various purposes, as—1stly, to reduce the frequency and force of the heart’s action; 2dly, to promote the action of the absorbents; 3dly, as a diuretic; and 4thly, sometimes on account of its specific influence over the cerebro-spinal system.

In the following remarks on the uses of foxglove in particular diseases, I refer to the administration of this remedy in the doses in which it is ordinarily employed. I have no experience of its therapeutic effects, when given in the enormous quantities mentioned by Dr. Clutterbuck.

1. In fever.—Digitalis is occasionally useful in fever to reduce the frequency of the pulse, when the excitement of the vascular system is out of proportion to the other symptoms of fever, such as the increased temperature, and the cerebral or gastric disorder. It cannot, however, be regarded, in the most remote way, as a curative means; on the other hand, it is sometimes hurtful. Thus, not unfrequently it fails to reduce the circulation; nay, occasionally, it has the reverse effect, accelerates the pulse, while it increases the cerebral disorder, and perhaps irritates the stomach. In estimating its value as a remedial agent for fever, we must not regard it as a sedative means (I refer now to the vascular system) merely; it is an agent which exercises a specific influence over the brain; and, therefore, to be able to lay down correct indications or contraindications for its use in disordered conditions of this viscus, we ought to be acquainted, on the one hand, with the precise nature of the influence of the remedy, and, on the other, with the actual condition of the brain in the disease which we wish to relieve. Now, as we possess neither of these data in reference to fever, our use of foxglove is, with the exception of the sedative influence over the circulation, empirical; and experience has fully shown us it is not generally beneficial. But, I repeat, where the frequency of pulse bears no relation to the local or constitutional symptoms of fever, foxglove may be serviceable.

2. Inflammation.—Foxglove has been employed in inflammatory diseases, principally on account of its power of reducing the frequency of the pulse, though some have referred part of its beneficial operation to its influence over the absorbent system. Inflammation, of a chronic kind, may be going on in one part of the body, to an extent sufficient to produce complete disorganization, and ultimately to cause the death of the patient, without the action of the larger arterial trunks (i. e. of

---

\(^1\) Lond. Med. Gaz. vol. i. p. 744.
the system generally) being remarkably increased. In such cases, digitalis is, for the most part, of little use. Again, in violent and acute inflammation, accompanied with great excitement of the general circulation, especially in plethoric subjects, foxglove is, in some cases, hurtful; in others, it is a trivial and unimportant remedy; and we therefore rely, in our treatment, on bloodletting, and other powerful antiphlogistic measures; and foxglove, if serviceable at all, can only be used after the other means.

As a remedy for inflammation, foxglove is principally useful in less violent cases, particularly when accompanied with increased frequency of pulse, and occurring in subjects not able to support copious evacuations of blood. Moreover, it has more influence over inflammation of some parts of the body (as the arachnoid membrane, the pleura, the pericardium, and the lungs) than of others. In gastric and enteric inflammation, it would appear to be objectionable on account of its irritant properties; while its specific influence over the brain would make it a doubtful remedy in phrenitis. In arachnitis of children it is certainly a most valuable agent.

In conclusion, then, it appears that digitalis, as a remedy for inflammation, is principally valuable where the disease has a tendency to terminate in serous effusion. But in no case can it be regarded as a substitute for bloodletting. Its powers as an antiphlogistic remedy have, I suspect, been greatly overrated.

3. Dropsy.—Of all remedies for dropsy, none have gained more, and few so much, celebrity as foxglove. It has been supposed to owe its beneficial operation to its repressing arterial excitement, to its promoting the functions of the absorbent vessels, and particularly to its diuretic effects. Whatever may be its modus operandi, its powerful and salutary influence in many dropsies cannot be a matter of doubt. Dr. Withering has observed, that "it seldom succeeds in men of great natural strength, of tense fibre, of warm skin, of florid complexion, or in those with a tight and cordy pulse." "On the contrary, if the pulse be feeble or intermittent, the countenance pale, the lips livid, the skin cold, the swollen belly soft and fluctuating, or the anasarous limbs readily pitting under the pressure of the finger, we may expect the diuretic effects to follow in a kindly manner." In those with a florid complexion, bloodletting and purgatives will often be found useful preparatives for foxglove. In some forms of dropsy, foxglove is more serviceable than in others. Thus, anasarca, ascites, hydrothorax, and phlegmasia dolens, are sometimes benefited by it; whereas ovarian dropsy and hydrocephalus are not relieved by it. Its diuretic effect is greatly promoted by combining other diuretics with it, especially squills (as in the Pilulae Digitalis et Scillae, Ph. Ed.), calomel, or the saline diuretics (as the acetate of potash). A combination of vegetable bitters (as infusion of gentian or calumba) with foxglove, forms, I think, a valuable form of exhibition in many old dropsical cases. Infusion of common broom (Cytisus scoparius) might probably be advantageously conjoined with foxglove, where a powerful diuretic is required. In old cases of general dropsy, in edematous swellings from debility, and in anasarca following scarlet fever, where, together with weakness, there is still left an excited and irritable state of the arterial system, chalybeates (as the tinctura ferri sesquichloridi) may be conjoined with foxglove, with the happiest effects.1

4. In Hemorrhages.—In active hemorrhages from internal organs, accompanied with a quick, hard, and throbbing pulse, foxglove as a sedative is oftentimes serviceable. Epistaxis, haemoptysis, and menorrhagia, are the forms of hemorrhage more frequently benefited by the use of foxglove.

5. Diseases of the Heart and Great Vessels.—An important indication in the treatment of many diseases of the heart and great vessels is to reduce the force and velocity of the circulation. The most effectual means of fulfilling this indication are—the adoption of a low diet, repeated bloodletting, and the employment of foxglove. There are, perhaps, no diseases in which the beneficial effects of foxglove

1 Holland, Med. Notes and Reflect. p. 540.
are more marked than in those of the heart and great vessels. In aneurism of the aorta, our only hope of cure is by the coagulation of the blood in the aneurismal sac, and the consequent removal of the distensive pressure of the circulation. To promote this, we endeavour to retard the movement of the blood within the sac, by diminishing the quantity of blood in the system generally, and by reducing the force and velocity with which it circulates. Bloodletting and digitalis are, in these cases, very important agents; and under their use cases now and then recover. Again, in simple dilatation of the cavities of the heart, our objects are to remove, if possible, the cause (usually obstruction in the pulmonic or aortic system), to strengthen the muscular fibres of the heart, and to repress any preternatural excitement of the vascular system. Digitalis is useful to us in attaining the latter object. In simple hypertrophy or hypertrophy with dilatation, we have to reduce the preternatural thickness of the heart’s parietes, and this we do by removing, when it can be done, any obstruction to the circulation, by using a low diet, by repeated bloodletting, and by the employment of foxglove. No means, says the late Dr. Davies, excepting the abstraction of blood, diminishes the impulse of the heart so completely and so certainly as digitalis. “I have been,” adds he “in the habit of using it for several years for these affections, and have rarely seen it fail in producing at least temporary relief.” “The enlarged and flaccid heart,” observes Dr. Holland, “though, on first view, it might seem the least favourable for the use of the medicine, is, perhaps, not so. At least we have reason to believe, that, in dropsical affections, so often connected with this organic change, the action of digitalis, as a diuretic, is peculiarly of avail.” In some disordered conditions of innervation of the heart and great vessels—as in angina pectoris, nervous palpitation of the heart, and augmented arterial impulsion, foxglove is also at times—beneficial. In patients affected with an intermittent or otherwise irregular pulse, I have several times observed this medicine produce regularity of pulsation—a circumstance also noticed by Dr. Holland. Besides the preceding, there are various other affections of the heart in which foxglove may be found serviceable, either by its sedative influence over the circulation, or by its power of relieving dropsical effusion through its diuretic property.

6. In Phthisis.—Digitalis has been declared capable of curing pulmonary consumption, and numerous cases of supposed cures have been published. Bayle has collected from the writings of Sanders, Kinglake, Fowler, Beddoes, Drake, Mossman, Maclean, Ferrier, Magennis, Moreton, and others, reports of 151 cases treated by foxglove. Of these, 83 are said to have been cured, and 35 relieved. But a more accurate and extended experience has fully proved that this medicine possesses no curative, and very slightly palliative powers in genuine phthisis: it is totally incapable of preventing or of causing the removal of tubercular deposits, and has little, if any influence, in retarding the progress of consumption. Its power of diminishing the rapidity of the circulation cannot be doubted; but this effect is, as Dr. Holland justly remarks, “of less real moment than is generally supposed.”

7. In Insanity and Epilepsy.—In these maladies foxglove may prove occasionally serviceable by repressing excessive vascular excitement, which sometimes accompanies them. Furthermore, the specific influence of this remedy over the cerebro-spinal system may now and then contribute to the beneficial operation of foxglove. But the precise nature of this influence not having as yet been accurately ascertained, while the pathology of the above-mentioned diseases is involved in considerable obscurity, it follows that the therapeutic value of this influence can only be ascertained empirically. In insanity, Dr. Hallaran recommends foxglove to reduce vascular action after the employment of depletion and purgation. It has

---

5 On Insomni.
6 Inquiry, &c. with Observ. on the Cure of Insanity, 1810.
8 Op. ante cit.
been used in this disease, with success, by Dr. Currie, and by Fanzago. In epilepsy it is, I conceive, less likely to be serviceable, because this disease is less frequently accompanied with the vascular excitement, against which foxglove is most successful. Accordingly, while in some cases it has appeared to act beneficially, in others it has either been unsuccessful, or has only given temporary relief.

8. In various other diseases.—Besides the preceding, there are several other maladies against which foxglove has been employed with occasional benefit, as scrofula and asthma. For other diseases relieved by foxglove I must refer the reader to the works of Murray and Bayle.

Administration.—The ordinary dose of foxglove, in powder, is from gr. ss to gr. iss, repeated every six hours.

Antidotes.—In a case of poisoning by foxglove, or its preparations, expel the poison from the stomach by the stomach-pump or by emetics, if vomiting should not have already commenced; assist the vomiting, when it is established, by the use of diluents; and counteract the depressing influence of the poison on the circulation by the use of ammonia and brandy; and keep the patient in a recumbent posture, to guard against syncope. I am unacquainted with any chemical antidote for foxglove; perhaps infusion of nutgalls might prove serviceable by the tannic acid which it contains.

1. Infusum Digitalis, L. E. D. [U. S.]; Infusion of Foxglove.—(Foxglove leaves, dried, 3j [3i j, E.]; [Spirit of Cinnamon f3 j, L., f5 ij, E.]; Boiling [distilled, L.] Water 0j [f5 xvi j, E.; 3i x, D.]. Macerate the foxglove leaves in the water for four [one, D.] hours, in a vessel lightly covered, and strain [through linen or calico, E.]; then add the spirit.—[The U. S. Pharm. directs Foxglove 5j; Boiling Water Ose; Tincture of Cinnamon f5 j. Macerate the foxglove with the water for two hours in a covered vessel and strain, then add the tincture of cinnamon].—I believe this, when properly made, to be the most effectual of the preparations of foxglove. The dose of it is from f3 ss to f5 j, repeated every six hours. I have known it given to the extent of f3 x j.

2. Tinctura Digitalis, L. E. D. [U. S.]; Tincture of Foxglove.—(Foxglove leaves, dried [in moderately fine powder, E.]; in coarse powder, D.], 3iv [3v, D.]; Proof Spirit [Diluted Alcohol, U. S.] Oj. Macerate for seven [fourteen, D.] days, then express and strain. "This tincture is best prepared by the process of percolation, as directed for the tincture of capsicum. If forty fluidounces of the spirit be passed through, the density is 944 [0.944], and the solid contents of a fluidounce amount to twenty-four grains. It may also be made by digestion," E.)—The usual dose of this preparation, for an adult, is mxx, cautiously increased to mxl, repeated every six hours. I usually begin with mxx. The largest dose I have employed is f5 j; but, as I have already stated, it has been given to the extent of one ounce! The colour of this preparation is somewhat affected by exposure to strong solar light.

Success Digitalis.—The preserved juice of foxglove may be employed as a substitute for the tincture. From 1 cwt. 2 qrs. 26 lbs. of digitalis gathered in May, 49 pints of juice have been obtained.

3. Extractum Digitalis, E.; Extract of Foxglove.—("This extract is best prepared from the fresh leaves of digitalis, by any of the processes indicated for extract of conium," E.)—Recently introduced into the pharmacopœia of Edinburgh. Its preparation requires very great care and attention, or the virtues of the plant may be destroyed during the process. Dose, gr. j, cautiously increased.
4. PILULE DIGITALIS ET SCIILE, E.: Pills of Foxglove and Squill.—(Digitalis; Squill, of each one part; Aromatic Electuary two parts. Beat them into a proper mass with conserve of red roses; and divide the mass into four-grain pills.)—A valuable diuretic compound. Used in dropsies. Dose, one or two pills.

ORDER XLII. SOLANACEÆ, Lindley.—NIGHTSHADES.

SOLANUM, Jussieu.

Characters.—Calyx 5-parted, seldom 4-parted, persistent, inferior. Corolla monopetalous, hypogynous; the limb 5-cleft, seldom 4-cleft, regular, or somewhat unequal, deciduous; the stamens inserted upon the corolla, as many as the segments of the limb, with which they are alternate; anthers bursting longitudinally, rarely by pores at the apex. Ovary 2-celled, composed of a pair of carpels right and left of the axis, rarely 4—5 or many-celled, with polysemous placenta; style continuous; stigma simple; sepals numerous, amphiropetal. Pericarp with 2 or 4 or many cells, either a capsule with a double dissemination parallel with the valves, or a berry with the placenta adhering to the disseminum. Seeds numerous, sessile; embryo straight or curved often out of the centre, lying in a fleshy albumen; radicle next the hilum. Herbaceous plants or shrubs. Leaves alternate, undivided, or lobed, sometimes collateral; the floral ones sometimes double, and placed near each other. Inflorescence variable, often out of the axil; the pedicels without bracts (Lindley).

Properties.—The narcotic properties which many members of this order possess depend on the presence of vegetable alkaloids; but the narcotism which they induce is very different to that caused by opium; hyoscyamus, belladonna, and stramonium, give rise to phantasms and dilatation of the pupil (see the Solanaceæ mydriatica, vol. i. p. 237); nicotiana is a nauseating cardacio-vascular sedative (see ante, pp. 237 and 258). An acrid resin is found in many species; on this the hot, pungent, burning qualities of capsicum depend. A bitter principle confers on some species (as S. Pseudquinina and crispum) tonic properties. Starch abounds in potatoes, which owe their nutritive qualities chiefly to it.

171. HYOSCYAMUS NIGER, Linn.—COMMON HENBANE.

Sex. Syst. Pentandria, Monogynia.

(Herba biennis. Foliae caulinae recens et exsiccatum, L.—Leaves, E. D.)

History.—This plant is the Τοσκίαλος μέθας of Dioscorides, the hyoscyamus niger of Pliny.¹

Botany. Gen. Char.—Calyx urceolate, 5-toothed. Corolla funnel-shaped; the limb plaited, 5-lobed; the lobes obtuse, unequal. Stamens 5, inserted in the lower part of the tube of the corolla, inclosed or exserted, deciduate; anthers deceasing longitudinally. Ovary 2-celled; placenta fixed to the dorsal disseminum; ovules numerous; style simple; stigma capitate. Capsule inclosed by the persistent often enlarged calyx, narrowed from the ventricose base, membranous, 2-celled, circumscissile at the apex, with a 2-celled lid. Seeds many, kidney-shaped; embryo in fleshy albumen, almost pellucid, curved (Endlicher).

Sp. Char.—Leaves oblong, pinatifid, or sinuate sessile, and subamplexiculae; lower leaves stalked. Flowers nearly sessile, axillary, unilateral (Babington).

Root spindle-shaped. Stem bushy. Leaves soft and pliant, sharply lobed. Whole herbage glandular, downy, and viscid, exhaling a powerful fetid and oppressive odour. Flowers numerous from the bosoms of the crowded upper leaves, dropping, almost entirely sessile, of an elegant straw colour, usually pencilled with dark purple veins.

Hab.—Indigenous; waste ground, banks, and commons. Flowers in July.

There are two varieties of this species; one biennial, the other annual. Both are cultivated at Mitcham.

¹ The generalisations of some late French writers (Troussseau and Picot, Traité de Thérap., t. i. p. 266), with respect to the identity of the operation of the narcotic Solanum, do not appear to me to be founded in fact.

² Hist. Nat. lib. xxv. cap. 17, ed. Vaip.

VOL. II.—30

Var. a biennis; Biennial Black Henbane.—This is larger, stronger, more branched, more clammy, than the annual variety. Its root is biennial. Cultivated at Mitcham. During the first year of its growth the plant has no aerial stem, all the leaves being radical and stalked. It is less odoriferous and clammy than the mature plant; and Dr. Houlton¹ states that it yields less extract. In the autumn the leaves die, but the root survives during the winter; and in the following spring sends up an aerial stem, which grows to the height of from two to four feet. The leaves of the second year are large, deeply sinuate, or pinnatifid. It flowers towards the end of May, or in June.

As this variety is more highly developed than the annual sort, it probably possesses more medicinal activity; and, therefore, should be preferred. I am, however, unacquainted with any experiments demonstrative of its superiority.

This variety flowers earlier than the annual sort. The surest plan of obtaining it, therefore, is to purchase it fresh while in flower.

Var. β annua, Sims, Bot. Mag. 2394; H. agrestis. Kitaibel ex Schult. Fl. Aust., ed. 2, p. 383; H. niger, var. β minor, Brandt u. Ratzeburg, Deutschl. phan. Giftgewächse; H. niger, var. β agrestis, Nees in Linn. Trans. xvii. 77; Annual or Field Henbane.—Root annual; stem simple, downy; leaves smooth, sinuate, or pinnatifid; flowers sessile; corolla reticulated.—Indigenous; South of Europe; North of India.—Cultivated at Mitcham for medicinal use.—Flowers in July and August.

The plant is smaller, the leaves less deeply sinuated (not pinnatifid), less hairy, clammy, and fetid than var. α biennis.

* Corolla non violacea reticulata; H. pallidus, Koch; Babing. Man., of Br. Botany.—This is a subvariety of β annua, with yellow corolla, without any purple veins. It is said to grow wild at Esher, in Surrey.

Hyoscyamus albus, Linn. Υσςζ&μος λευκος, Diosc. lib. iv. cap. 69.—Leaves petiolate; lower ones orbicular, entire; the rest from cordate to ovate at the base, sinuated; flowers sessile.—South of Europe. Annual. Its medicinal properties resemble those of H. niger, for which it has sometimes been employed in medicine.²

DESCRIPTION.—The herb (herba hyoscyami), when fresh, has a strong, unpleasant, narcotic odour, a mucilaginous, slightly acrid taste, and a clammy feel. It should be gathered when in full flower. By drying, it almost wholly loses these properties. One hundred pounds of the fresh herb yield about fourteen pounds when dried.³ The leaves (folia hyoscyami), when fresh, are pale dull green. The seeds (semina hyoscyami) are small, compressed, uniform, roundish, finely dotted, of a yellowish-gray colour, and have the odour of the plant, and an oleaginous, bitter taste.

Sessile, oblong, acutely sinuated, somewhat pubescent, with viscid fetid hairs. It is to be gathered and dried as ordered for foxglove. The herb which grows wild in waste places is to be preferred to that which is cultivated in gardens, L.

COMPOSITION.—The seeds of Hyoscyamus niger were analyzed in 1816 by Kirchhoff,⁴ and in 1820 by Brandes.⁵ The extract of the herb was analyzed by Lindberg⁶

Seeds of hyoscyamus 101.4

The ashes contained carbonate, phosphate, sulphate, and muriate of potash, carbonate and much phosphate of lime, much silica, manganese, iron, and minute traces of copper.

³ Martinus, Pharmacogna.
⁵ Ibid. Ed. xxx. 260.
1. **Hyosciamia** or **Hyoscyamia**.—This term has been applied to a vegetable alkalii procured from the seeds and herbs of *Hyoscyamus niger* by Brandes, whose statements have been confirmed by Geiger and Hesse, as well as by Mein. However, Chevallier, as well as Braunt and Poggialli, have failed to procure it. The properties assigned to it are almost identical with those of Atropins, from which it differs in being more soluble in water. It is crystallizable, has an acid taste, and, when volatilized, yields ammonia. Reisinger says, that a drop of a solution of one grain of this substance in ten grains of water caused dilatation of the pupil, but did not give rise to irritation of the eye. A solution of double this strength acted as an irritant.

2. **Emphysematous Oil of Henbane** (*Pyro-Hyoscyamia*).—This was obtained by Dr. Morries by the destructive distillation of henbane. Its chemical properties are identical with those of the emphysematous oil of foxglove. It proved a powerful narcotic poison.

**Physiological Effects.**

a. **On Vegetables.**—Water holding in solution extract of henbane proved poisonous to *Hyoscyamus niger*.

b. **On Animals.**—Its effects on herbivorous animals are slight. Given to horses in large quantities, it causes dilatation of the pupils, spasmodic movements of the lips, and frequency of pulse. On dogs its effects appear to be analogous to those on man. It does not cause any local irritation. Its constitutional effects are dilatation of pupil, weakness of the posterior extremities, staggering, and insensibility.

c. **On Man.**—In small and repeated doses, henbane has a calming, soothing, and tranquillizing effect. This is especially observed in persons suffering with great nervous irritability, and with a too active condition of the sensorial functions. In such it frequently causes quietude, with a tendency to sleep. It frequently allays irritation and preternatural sensibility existing in any organ. It does not quicken the pulse, check secretion, or cause constipation. *Large doses* sometimes induce sleep. Fouquier, however, deues this. He says henbane causes headache, giddiness, dimness of sight, dilatation of pupil, a greater or less tendency to sleep, and painful delirium. In some cases these symptoms are followed by thirst, nausea, gripping, and either purging or constipation; and in a few instances febrile heat and irritation of skin are induced. But I have frequently seen sleep follow its use, though its hypothic properties are neither constant nor powerful. It more frequently fails to occasion sleep in those accustomed to the use of opium. Very large doses are apt to be followed by delirium rather than by sleep. Its power of alleviating pain and allaying spasm is greatly inferior to that of opium. *In poisonous doses* it causes loss of speech, dilatation of pupil, disturbance of vision (presbyopia), distortion of face, coma, and delirium, generally of the unmanageable, sometimes of the furious kind, and phantasms; and paralysis, occasionally with convulsive movements. Irritation of the stomach and bowels (manifested by nausea, vomiting, pain, and purging) is occasionally induced. One author says *Hyoscyamus* renders the hair gray, while another states that it darkens it.

In its operation on the body, henbane presents several peculiarities (see vol. i. p. 237). From opium it is distinguished by the sedative rather than stimulant effects of small doses; by its not confusing the bowels; by the obscurity of vision (presbyopia); and when swallowed in large doses, by its producing dilatation of the pupil, and by its being more apt to occasion delirium with phantasms. Furthermore, in some individuals opium causes headache and other distressing symptoms which henbane is not so apt to produce. From belladonna and stramonium, to which it is in several respects closely allied, it is distinguished by the very rare occurrence of any symptoms of gastro-intestinal irritation after the ingestion of large doses of it. Sundelin says "that it wants the resolvent operation and the stimu-
lant influence over the vascular system which belladonna possesses." Vogt ranks 
hyoscyamus between belladonna and hydrocyanic acid. But with every respect for 
the opinions of so profound a writer, I cannot concur in the propriety of this 
arrangement. I have never seen, from the use of hydrocyanic acid, the same 
tranquillizing and soothing influence over the mind and external senses which I 
have repeatedly witnessed from the use of small doses of hyoscyamus; and the 
effects of poisonous doses of these two agents more strikingly display the difference 
of their operation; for, while hydrocyanic acid causes insensibility and convulsion, 
henbane produces delirium and paralysis.

Uses.—Hyoscyamus is said to alleviate pain and irritation in various organs, to 
promote sleep, to procure quietude, and to obviate spasm. For any of these ob-
jects it is greatly inferior to, and less confidently to be relied on than opium. Yet 
it is, on various occasions, preferred to the latter; as where opium causes headache 
or other distressing cerebral symptoms, or where it occasions constipation. Again, 
the stimulant influence of small doses of opium over the vascular system, and the 
tendency of this narcotic to lock up the secretions and excretions, form objections 
to its use in the maladies of children; in such, therefore, hyoscyamus is frequently 
preferred. Fouquier, whose observations with respect to the effects of henbane I 
have already had occasion to refer to, can find in this narcotic no useful property; 
and he thinks it ought to be banished from the Materia Medica.9

The following are the principal purposes for which it is ordinarily employed in 
this country:

1. As an anodyne, where opium disagree or is from any circumstance objection-
able. It may be used in neuralgia, rheumatism, gout, periostitis, the milk abscess, 
painful affections of the urino-genital organs, scirrhus, and carcinoma.

2. As a calmer and soporific, it is available in sleeplessness accompanied with 
great restlessness and mental irritability, and where opium, from its stimulant or 
other properties, proves injurious. Sometimes, where it fails to cause actual sleep, 
it proves highly serviceable by producing a calm and tranquil state conducive to the 
well-doing and comfort of the patient.

3. As an antispasmodic, it occasionally proves serviceable in spasmodic affections 
of the organs of respiration (e. g. spasmodic asthma) and of the urino-genital appa-
ratus (e. g. spasmodic stricture and spasm of the sphincter vesicae). Notwithstanding 
the favourable reports of Storeck to the contrary, it is rarely calculated to be of 
any service in epilepsy.

4. As a sedative, to allay irritation and preternatural sensibility. In troub-
some cough it sometimes proves useful, by dulling the sensibility of the bronchial 
membrane to the influence of the cold air. In nephritic and vesical irritation, and 
in gonorrhoea, it is sometimes a useful substitute for opium. In the irritation of 
teething it is valuable, from its power of relieving pain and convulsion. Its ad-
vantages over opium, in the disorders of children, have been already pointed out.

5. To dilate the pupil, the extract may be used as a substitute for extract of bella-
donna, than which it is less powerful.

6. As a topical sedative and anodyne, fomentations of the herb or the extract are 
sometimes applied to painful glandular swellings, irritable ulcers, hemorrhoids, and 
parts affected with neuralgia. In irritation of the rectum or bladder it is sometimes 
used per anum.

Administration.—The powder of the leaves is rarely employed; the dose is 
from three to ten grains. The extract and tincture are the preparations commonly 
used.

Antidotes.—The treatment of a case of poisoning by henbane is the same as 
that by opium.

1. Tinctura Hyoscyami, L. E. D. [U. S.]; Tincture of Henbane.—(Henbane 
leaves, dried [in moderately fine powder, E; in coarse powder], 3v [3iv, U. S.];

1 Lehrb. d. Pharmakol. Bd. i. S. 170, 2te Aufl.  
Proof Spirit [Diluted Alcohol, U. S.] Oij. Macerate for seven [fourteen, D.] days, then express and strain. "This tincture is best prepared by the process of percolation, as directed for tincture of capsicum; but it may also be obtained, though with greater loss, by the process of digestion," E.—Dose, \(13\) to \(13\) j[^3].

Succus Hyoscyami.—The Preserved Juice of Henbane may be substituted for the tincture. The following are the quantities of juice obtained from henbane leaves:

\[
\begin{array}{c|c|c}
\text{Imperial Quarts of Juice.} & \text{Yielded of} & \text{Yielded of} \\
\text{July 21. 3 cwt. of leaves} & \text{Juice.} & \text{Extract.} \\
\text{July 22. 2 cwt. of leaves} & \text{lbs.} & \text{lbs. oz.} \\
\text{Aug. 3. 2 cwt. of leaves} & \text{30} & 42 = 4.10 \\
\end{array}
\]

The leaves, the very fine summits of the stalks, the flowers and seeds, already formed, weighed \(35\) lbs. 17\(\frac{1}{2}\) oz. Waste leaves and dirt \(34\) lbs. Lost by evaporation during the two hours occupied by picking \(112\) lbs. 5\(\frac{1}{2}\) oz.

The quality of the extract met with in the shops is extremely variable. This arises principally from the unequal care with which it has been prepared. The dose is from \(v\) to \(\bar{v}\). Occasionally, very much larger doses have been taken without any injurious effects. It is a valuable addition to the compound extract of colocynth, whose operation it renders milder, though not less efficacious. It is sometimes used as a topical application to inflamed or tender parts; thus, alone, or in the form of ointment, it is applied to painful hemorrhoids; spread on linen it forms a plaster which has been used in neuralgia, rheumatic pains, painful glandular swellings, &c.

My friend Dr. William Lobb, and nearly a dozen other persons, in 1841, experienced symptoms like those of poisoning by belladonna, from the employment of several grains of an extract sold by a most respectable country chemist as that of hyoscymus. The greater part of the extract sold by this chemist had been most carefully prepared by himself; but not having made sufficient for the year's consumption, he purchased some in London, and the extract used on these occasions might have been that which was bought. The extract employed had an unusually greenish colour, and the hyoscymus odour. The effects produced were difficulty of swallowing, a sensation as if the parts about the throat had been powdered with tow dust, impaired vision (presbyopia), eyes bloodshot, pupils dilated, feeling of suffocation, strangury, cessation of cough and expectoration which had been previously troublesome. The vision was greatly improved by the use of a magnifier. The third day the symptoms had disappeared, but great prostration of strength supervened. In some of the patients an eruption like that of scarlatina appeared, with intense redness of the palms of the hands.

3. Extractum Hyoscyami Alcoholicum, U. S.—(Take of Henbane Leaves, in coarse powder, a pound; Diluted Alcohol four pints. Moisten with the alcohol [half pint], and, having allowed the mixture to stand 24 hours, transfer to an apparatus for displacement, and gradually add the remainder of the diluted alcohol. When the last portion shall have penetrated the leaves, pour in sufficient water from
time to time to keep the powder covered. Cease to filter when the liquid which passes begins to produce a precipitate as it falls. Distil off the alcohol from the filtered liquor, and evaporate the residue to the proper consistence.)—This preparation is intended as a substitute for the preceding, as the fresh herb cannot be obtained in sufficient quantity in the United States. It is a fine, clear, dark, shining extract, is possessed of the active properties of the drug, and may be employed in lieu of the common extract. The dose is gr. j to gr. v, or larger quantities if required.]

172. ATROPA BELLADONNA, Linna.—COMMON DWALE; DEADLY NIGHTSHADE.

**Sex. Syst. Pentandria, Monogynia.**

(Atripia; alkali e radice comparatum cristallis; Folium recens et exsiccatum, L.—Leaves, E.—The leaves and root, D.)

**History.**—Belladonna, being a native of both Greece and Italy, was doubtless known to, and described by, the ancient Greek and Roman writers. Modern botanists, however, have been unable to identify it with certainty. Fraas is of opinion that it is the **Mandragora** of Theophrastus, the **Στρύγος μανικις** ("άνθος μικλα") of Dioscorides, the third sort of **Strychnos (Solanum)** of Pliny. But this notion is not without its difficulties. The plant which Theophrastus mentions under the same name had a stem like the **ώδης** (ferula), and a black racemose fruit with a vinous taste. Now the stem of belladonna certainly does not resemble that of an umbelliferous plant, nor is the fruit racemose. Sibthorp and Smith, in my opinion, only exercised a proper precaution in not assigning any ancient synonyme to belladonna.

The earliest undoubted notice of belladonna occurs in the work of Tragus (A. D. 1532), who calls it **Solanum hortense nigrum.** It has been supposed that it was this plant which produced such remarkable and fatal effects on the Roman soldiers during their retreat from the Parthians. Buchanan relates that the Scots mixed the juice of this plant with the bread and drink, which, by their truce, they were to supply the Danes, which so intoxicated them, that the Scots killed the greatest part of Sweno's army while asleep. Shakspeare is supposed to allude to it under the name of the **insane root.**

**Botany. Gen. Char.—Calyx 5-parted. Corolla hypogynous, funnel-shaped, campanulate; the limb plaited, 5—10-eleft. Stamens 5, inserted into the lower part of the corolla, exserted, or nearly so; filaments filiform; anthers dehiscing longitudinally. Ovary 2-celled; placenta inserted in a line on the dorsal dissepiment; ovules numerous; style simple; stigma peltato-depressed. Berry supported by the spreading calyx, 2-celled. Seeds many, subreniform; embryo in fleshy albumen, subperipherical, arched or annular (Endlicher).**

**Sp. Char.—Stem herbaceous. Leaves broadly-ovate, entire. Flowers solitary, axillary on short stalks (C. C. Babington).**

**Root fleshy, creeping. Whole plant fetid when bruised, of a dark and lurid aspect, indicative of its deadly narcotic quality. Stems herbaceous, 3 feet high, round, branched, leafy, slightly downy. Leaves lateral, mostly 2 together of unequal size, ovate, acute, entire, smooth. Flowers imperfectly axillary, solitary, stalked, drooping, dark full purple in the border, paler downwards, about an inch long. Berry of a shining violet black, the size of a small cherry, sweetish, and not nauseous (Smith).**

**Hab.**—Indigenous; hedges and waste ground, on a calcareous soil. Flowers in June.

5. Macbeth, Act i. Scene 3d.
DEADLY NIGHTSHADE:—DESCRIPTION; PHYSIOLOGICAL EFFECTS. 471

DESCRIPTION.—The root (radix belladonnae), when fresh, is one or more inches thick, and sometimes a foot or more long; it is branching, fleshy, internally white, externally grayish or brownish-white. Its taste is slight, sweetish; its odour feeble. It may be collected in the autumn or early in the spring. The flowering stems (herba belladonnae) are collected in June or July; they are then deprived of leaves (folia belladonnae), which are to be carefully dried. The leaves, when fresh, have a feeble, bitterish, sub-acid taste.

Oval, acute, quite entire, smooth, when bruised evolves an unpleasant odour.

The herb which grows spontaneously in hedges and uncultivated places is to be preferred to that cultivated in gardens.—Ph. Lond.

COMPOSITION. The leaves of belladonna were analyzed, in 1808, by Melandri;¹ the expressed juice, in 1809, by Vauquelin;² and the dried herb, in 1819, by Brandes.³ Besides these, there have been several less complete examinations of this plant by other chemists, which have yielded more or less interesting results.

1. ATROPIN.—(See p. 478.)

2. PSEUDOTOXIN.—A substance obtained by Brandes from the watery extract of belladonna. It is a brownish-yellow, soluble in water, insoluble in absolute alcohol and ether, is coloured green by the salts of iron, and is totally precipitated from its watery solution by the salts of lead, and by tincture of galls.⁴

3. BELLADONNIN.—Under this name, Luebekind⁵ has described a volatile vegetable alkali, which, he says, is distinct from atropin. It is crystallizable, and has an ammoniacal odour. It consists of carbon 28.5, hydrogen 22.4, nitrogen 32.1, oxygen 17.0. The crystals contain three equivalents of water. Two grains caused extreme heat in the throat, and constriction of the larynx.

4. ATROPIC ACID.—This name has been given by Richter⁶ to a volatile, crystallizable acid, distinguished from benzoic acid by its not precipitating the salts of iron.

PHYSIOLOGICAL EFFECTS. a. On Vegetables.—An aqueous solution of extract of belladonna is poisonous to plants.⁷

b. On Animals generally.—Belladonna proves poisonous to animals and birds; but much less so to herbivorous than to carnivorous animals. Eight pounds (Troy) of the leaves have been eaten by a horse without any ill effects.⁸ The late Mr. Anderson told me that the blackbirds eat the seeds at the Chelsea Garden with impunity. A pound of ripe berries has been given to an ass with very little effect.⁹ Given to dogs, belladonna causes dilatation of pupil, plaintive cries, efforts to vomit, weakness of the posterior extremities, staggering, frequent pulse, a state like intoxication, and death.⁰ Forty or fifty grains of the watery extract, injected into the jugular vein of dogs, have proved fatal.¹¹ Flourens¹² thinks that the tubercula quadrigemina are the parts of the nervous centres on which this poison specifically acts. His inferences were drawn from experiments made on birds. The topical action of belladonna is that of an acrid, though not a very violent one.¹³

γ. On Man.—In the first degree of its operation, belladonna diminishes sensibility and irritability. This effect (called by some sedative) is scarcely obvious in the healthy organism, but is well seen in morbid states, when these properties are preternaturally increased. A very frequent, and sometimes the earliest, obvious effect of belladonna is dryness of the mouth and throat, frequently attended with thirst. The other secretions and the circulation are oftentimes not affected, though occasionally they are augmented. Mr. Bailey4 "asserts that belladonna affects neither the stomach nor bowels, nor any of the secretions nor excrections, those of the salivary glands excepted." The asserted influence of belladonna over the organic functions is said to be shown by its power of inducing, in some cases, resolution of swellings and tumours of various kinds, as will be presently noticed.

In the second degree of its operation, belladonna manifests, both in healthy and morbid conditions, its remarkable influence over the cerebro-spinal system. It causes dilatation of the pupils (mydriasis), presbyopia, or long-sightedness, with obscurity of vision, or absolute blindness (amaurosis), visual illusions (phantasms), suffused eyes, occasionally disturbance of hearing (as singing in the ears, &c.), numbness of the face, confusion of head, giddiness, and delirium, which at times resembles intoxication, and may be combined with or followed by sopor. These symptoms are usually preceded by a febrile condition, attended with a remarkable affecion of the mouth, throat, and adjacent parts. Besides dryness of these parts, it causes difficulty of deglutition and of articulation, a feeling of constriction about the throat, nausea, and sometimes actual vomiting, and, now and then, swelling and redness of the face. The pulse is usually hurried and small. The cutaneous, renal, and mucous secretions are frequently augmented. An exanthematous eruption, like that of scarlet fever, has been noticed; and irritation of the urinary organs, has in some instances occurred.8

In some cases very severe effects have been induced by the application of the extract to abraded surfaces.3 The continued application of it to the sound skin has also been attended with similar effects.4

In the third degree of its operation, belladonna produces effects similar to the preceding, but in a more violent form. The following are the symptoms experienced by above 150 soldiers, who were poisoned by the berries of belladonna, which were gathered at Pirna, near Dresden:4 Dilatation and immobility of the pupil; almost complete insensibility of the eye to the presence of external objects, or at least confused vision; injection of the conjunctiva with a bluish blood; protrusion of the eye, which in some appeared as if it were dull, and in others ardent and furious; dryness of the lips, tongue, palate, and throat; deglutition difficult or even impossible; nausea not followed by vomiting; feeling of weakness, lipothymia, syncope; difficulty or impossibility of standing, frequent bending forward of the trunk; continual motion of the hands and fingers; gay delirium, with a vacant smile; aphonia or confused sounds, uttered with pain; probably ineffecual desires of going to stool; gradual restoration to health and reason, without any recollection of the preceding state.75

Seven cases (two of which proved fatal) of poisoning by belladonna berries have occurred under my notice in the London Hospital; of these, a report has been published by Dr. Letheby.6 The phenomena were tolerably uniform. The following symptoms especially attracted my attention:—

1. Dryness of the fauces.—The excessive dryness of all the parts about the throat contributed greatly to the difficulty of swallowing and alteration of voice.

2. Scarlet eruption.—In several cases a scarlet eruption appeared on the arms and legs.

3. Mydriasis and presbyopia.—Mydriasis, or dilatation of the pupil, was present in every case; and was accompanied, in all the cases in which the patient was in a fit state for observation,

---

1 Observations Relative to the Use of Belladonna, p. 9, 1818.
5 Gauthier de Clabry, in Orfila's Traité de l'Examen. Général.
with presbyopia, or long-sightedness. These two symptoms depend, as I have before stated (see vol. i. p. 245), on the paralyzing influence of belladonna on the muscular fibres of the iris, by which mydriasis is produced, and on the ciliary muscle, by which the adjusting power of the eye is impaired. I strongly suspect that the impaired vision which has been ascribed to the use of belladonna is chiefly or entirely presbyopia. In one of the patients (a woman) above alluded to, the vision was so much impaired that she could not see to read; and when I placed the prayer card in her hand, she held it upside down, and declared her inability to distinguish the letters or words on it. But after trying several pairs of spectacles, borrowed of patients and others in the ward, she found one (magnifiers) which enabled her to read with ease. This agrees with the results of experiments of Müller on himself. This physiologist found that, by the local action of belladonna on one eye, he caused presbyopia of that eye, and thus gave rise to an unequal refractive power of the two eyes. Moreover, it accords with the effects experienced on his own person by Dr. Lobb, who informs me that he could see objects at a distance (as on the opposite side of the street), but could not distinguish a letter or a word in a book; but, by the aid of a magnifying-glass or powerful spectacles, he could read distinctly the smallest print.

4. Delirium; Phantasm.—The delirium was of the cheerful or wild sort, amounting in some cases to actual frenzy. In some of the patients it subsided into a kind of sleep attended with pleasant dreams, which provoked laughter. The delirium was attended with phantasm; and in this respect resembled that caused by alcohol (delirium et potu); but the mind did not run on cats, rats, and mice, as in the case of drunkards. Sometimes the phantasms appeared to be in the air, and various attempts were made to catch or chase them with the hands; at other times they were supposed to be on the bed. One patient (a woman) fancied the sheets were covered with cucumbers. The production of phantasms by belladonna was known to Linnaeus, who calls this agent "a phantastik," (see ante, p. 237).

5. Convulsions; Paralysis; Sopor or Coma.—In most of the cases, the power of the will over the muscles was so far disordered, that the muscular movements were somewhat irregular, causing a kind of staggering or jerking; but actual convulsions were not general. There was sopor, which terminated in coma, with a weakened or paralytic condition of the muscles.

The active principle of belladonna becomes absorbed and is thrown out of the urine, in which secretion both Runge and Dr. Letheby have detected it (see vol. i. p. 152, foot-note).

In comparing the operation of belladonna with that of other cerebro-spinals (see vol. i. p. 285), the most remarkable symptoms which attract our attention are the dilatation of the pupils, with insensibility of the irides to light, disturbance of vision (presbyopia), giddiness, staggering, the delirium (extravagant, pleasing, or furious), with phantasms, followed by sopor, and the remarkable affection of the mouth and throat (dryness of the throat, difficulty of deglutition and of articulation). Convulsions are rare, and, when they occur, are slight. Lethargy or sopor occurs subsequently to the delirium. Local irritation is not well marked.

These characters distinguish the effects of belladonna from those of any other substance, except henbane, stramonium, and perhaps from some other solanaceous species (see ante, p. 237).

When applied to the eyebrow, belladonna causes dilatation of the pupil, without necessarily affecting the other eye or disturbing vision. Segalas thought that absorption or imbibition was essential to this effect; but the action on the iris depends, according to Müller, not on the operation of the belladonna on the central organs of the nervous system, but on its topical, paralyzing influence on the ciliary nerves (see vol. i. p. 234). When, however, belladonna is swallowed, it is obvious that the irides can become affected through the general system only, and in this case the dilatation of the pupil is accompanied with disturbance of vision. The pneumogastric nerve is obviously concerned in producing the affection of the mouth, and the difficulty of deglutition and articulation.

The disorder of the intellect and of the external senses caused by belladonna proves that the influence of this agent is not limited to the excito-motory system,
but is extended to those portions of the nervous centres which are the seat of the intellect and of sensibility. I have, therefore, classed it among the phrenes (see vol. i. p. 235) and anaesthetics (see ante, p. 238).

Uses.—Belladonna has been employed to allay pain and nervous irritation (crethismus nervous, of some authors); to diminish the sensibility of the retina to the impression of light; to produce dilatation of the pupil; to counteract that condition of brain which is accompanied with contraction of the pupil; and to lessen rigidity and spasmodic contraction of muscular fibres. These uses obviously arise out of the ascertained physiological effects of the remedy. There are others, however, which may be regarded as altogether empirical; such as its employment to resolve or discuss scirrhous tumours.

The indications and contraindications for its use are not sufficiently established to induce us to place much confidence in them. My own experience leads me to believe that it is not a remedy fitted for phlethoric constitutions, or for febrile or acute inflammatory cases; and I am not disposed to admit the observations of Dr. Graves, hereafter to be mentioned, as offering any valid objections to these statements.

1. To allay pain and nervous irritation.—As an anodyne in most internal pains, no remedy hitherto proposed is equal to opium; but this agent totally fails us in many of those external pains known as neuralgia, prospalgia, or tic douloureux. In such cases, belladonna occasionally succeeds in abating, sometimes in completely removing pain; while it totally fails to give relief in the internal pains for which experience has found opium so efficacious. It is remarkable, therefore, that while both these cerebro-spinals (narcotics, auctor.) agree in lessening pain, they totally disagree as to the cases in which they succeed, and for which they are individually applicable. In the treatment of neuralgia, belladonna is employed both internally and externally. I believe that, to be successful, it requires, in many cases, to be persevered in until dryness of the throat, dilatation of pupil, and some disorder of vision are produced. Just as in many diseases for which mercury has been found a most efficient remedy, it is necessary to continue the use of this mineral until the mouth be affected, and often even to use it for some time afterwards. Of the success of belladonna in the treatment of neuralgia, we have abundant evidence in the published cases of Mr. Bailey, and of several other practitioners. My own experience of the use of this remedy leads me to regard it as very much inferior to aconite as a local remedy for this disease.

Besides neuralgia, there are many other painful affections against which belladonna is used as a local anodyne. Such are arthritic pains, painful ulcers, glandular enlargements which are tender to the touch, &c. Dr. Osborne says that, given internally, it causes an immediate cessation of the migratory or flying pains of rheumatism, without producing any effect on the fixed pains.

2. As an antispasmodic.—To relieve rigidity and spasmodic contraction of muscular fibres, belladonna sometimes proves serviceable as a topical remedy. In rigidity of the os uteri, during lingering labours or puerperal convulsions, the extract or an ointment of belladonna (see unguentum belladonnae) has been applied to the part by way of friction. Though the practice has been lauded by Chaussier, and adopted by Velpeau, Conquest, and others, yet it has not found much favour with British practitioners. It cannot be regarded as a substitute for, but only an adjuvant to depletion; and its use is not devoid of danger; for, not to insist on the possibility of absorption, and the consequent injurious effects therefrom, it is obvious that the long-continued friction of the tender womb, and the removal of the lubricating mucus, may dispose to inflammation. In spasmodic stricture of the urethra, and of the sphincters of the bladder and rectum, and in spasmodic con-

5 Outlines of Midwifery.
traction of the uterus, the topical use of the extract (smear on a bougie, applied to the perineum or other parts, or employed by way of a oyster) has in some cases appeared to give relief. In strangulated herna, it has been employed to produce relaxation of the abdominal muscles.

In a case of angina pectoris, unconnected with organic disease, the application of a belladonna plaster to the chest (before the ulcerations caused by tartar emetic ointment had healed) produced alarming signs of poisoning; but when these had subsided, all symptoms of the angina had totally disappeared.

Considerable relief has been gained in several cases of hooping-cough by the use of belladonna. Its occasional efficacy depends in part, probably, on its lessening the necessity of respiration, as well also on its power of obviating spasm of the bronchial tubes, and of decreasing the susceptibility of the bronchial membrane to the influence of the exciting causes of the paroxysms. But, like all other vaunted specifics for this peculiar disease, it frequently fails to give the least relief.

3. In maladies of the eyes.—Belladonna is applied to the eye for two purposes: the first, and the most common, is to dilate the pupil; the other is to diminish the preternatural sensibility of the retina to the impression of light. Dilatation of the pupil is sometimes produced, in certain diseases of the eye, in order to enable us to examine the condition of the refractive humours, and thereby to ascertain the nature and extent of the malady; as in cases of incipient cataract, which might otherwise be occasionally confounded with glaucoma or amaurosis. In the operation of cataract by solution or absorption (keratonyzis), the full dilatation of the pupil by belladonna is essential. In iritis, dilatation of the pupil is important, in order to prevent, or in recent cases to rupture, adhesions of the uvea to the capsule of the crystalline lens. Some surgeons consider it an objectionable remedy during the early stage of the disease. In prolapsus iridis, benefit is, under some circumstances, gained by the use of belladonna; as, where there is opacity of the cornea covering the pupil, the dilatation of the aperture, so as to get its circumference beyond the opaque spot, is attended with an improvement of vision. These are some of the cases in which dilatation of the pupil by belladonna is advisable. It is usually effected by applying the extract (see extractum belladonae) to the parts around the eye, or to the conjunctiva. The dilatation usually takes place within a few minutes, and sometimes continues for twenty-four hours.

Belladonna is sometimes employed in inflammatory and other affections of the eye, to diminish the morbid sensibility of this organ to the influence of light.

4. As a resolvent or discutient.—In enlargement and induration of the lymphatic glands, in scirrhus and cancer (or diseases which have been supposed to be such), belladonna has gained no slight repute from its supposed resolvent or discutient properties. That it may give relief by its anodyne powers we can easily understand, but that it has any real resolvent or discutient properties in the diseases just enumerated, may be reasonably doubted, notwithstanding the favourable reports of Gataker, Cullen, Blackett, and others. Bromfield and others have reported unfavourably of it, and no one, I think, now places any reliance on it.

5. As a prophylactic against scarlatina.—The introduction of belladonna into practice as a preventive of scarlet fever, is owing to the absurd homoeopathic axiom of "similia similibus curantur;" for, as this plant gives rise to an affection of the throat, and sometimes to a scarlet rash on the skin, its power of guarding the sys-
tem against the reception of scarlet fever has been assumed; and the assumption has been endeavoured to be established by an appeal to experience. Bayle has collected from various publications 2,027 cases of persons who took this medicine, and were exposed to the contagion; of these 1,948 escaped. Oppenheim gave it to 1,200 soldiers, and only twelve became affected. To the authorities here referred to may be added Hufeland and Koreff, who admit, from their own personal observations, the efficacy of the remedy, though they have not specified the number of cases in which they have tried it. But bearing in mind the well-known capriciousness evinced by scarlet fever (as indeed by other contagious disorders) in regard to the subjects of its attacks, and the large number of those who, though exposed to its influence, escape, the best evidence hitherto adduced in favour of the notion must be admitted to be inconclusive. While, therefore, the facts brought forward in favour of the existence of this prophylactic power are only negative, those which can be adduced against it are positive. For I conceive twenty cases of failure are more conclusive against the opinion here referred to, than one thousand of non-occurrence are in favour of it. Now Lehman, Barth, Wendl, Muhrbeck, Hoffmann, Bock, and many others that I could refer to, declare it has failed in their hands to evince its prophylactic powers. In this country we have no extended series of observations to quote; but the cases which I am acquainted with are decidedly against the efficacy of the remedy. A remarkable failure is mentioned by Dr. Sigmond, of a family of eleven persons who took the supposed specific, yet every individual contracted the disease.

6. In fever, with contraction of the pupil.—Dr. Graves has recently proposed the use of belladonna in those cases of fever with cerebral disease which are attended with contraction of the pupil. "It is not unreasonable," he observes, "to suppose that the state of the brain which accompanies dilatation of the pupil is different from that which accompanies contraction; and if belladonna has an effect in producing that cerebral state which is attended with dilatation, it is not going too far to infer, that its administration may do much towards counteracting the opposite condition; neither is it unphysiological to conclude, that if a remedy be capable of counteracting, or preventing, one very remarkable effect of a certain morbid state of the brain, it may also counteract other symptoms connected with the same condition." This line of argument, it must be admitted, is ingenious and plausible, and is supported by reference to several apparently successful cases treated on the principles here laid down. But I would observe, if the above reasoning were valid, opium should be serviceable in cerebral diseases attended with dilatation of pupil, since it causes contraction of this aperture. Now this is in direct opposition to our every-day experience of the uses of this important narcotic.

7. In other diseases.—Crueveilhier has found belladonna-smoking relieve some cases of phthisis. The fresh leaves were infused in a strong solution of opium, and then dried like tobacco; the patients began by smoking two pipes a day, and the quantity was gradually increased to six pipes. Perhaps this practice would be beneficial in spasmodic asthma and old catarrhs. In hydrophobia, notwithstanding the asserted prophylactic powers of this medicine, there is no valid ground for believing in its efficacy. I tried it in one case without success. In epilepsy, mania, hysteria, chorea, and some other maladies of the centro-spinal system, occasional benefit has resulted by the use of belladonna. In ileus, it has been most successfully used in the form of oyster, as a substitute for tobacco, which is objectionable on account of the horrible sickness and great depression which it causes.

Extract of Belladonna.

Administration.—The dose of the powder for an adult is one grain, which should be gradually increased until dryness of the throat, dilatation of pupil, or some head symptoms, are produced. For children, the dose at the commencement should be one-eighth of a grain. For internal as well as external use the extract or tincture is, however, commonly employed. For external use an infusion of the leaves is sometimes used as a fomentation, or is made into a poultice with bread or linseed meal.

Antidotes.—Similar to those for opium. After the use of evacuants the vegetable acids have appeared to give great relief. Decocation of nutgalls or green tea might probably prove serviceable.

1. Extractum Belladonnae, L. E. [U. S.]; Succus spissatus Belladonnae, D.; Extract of Belladonna.—(Fresh Belladonna Leaves lbj. Bruise them in a stone mortar; then press out the juice, and evaporate it, unstrained, to a proper consistence, L.—The Edinburgh College directs the expressed juice to be filtered, and then to be evaporated, in the vapour-bath, to the consistence of firm extract, stirring constantly towards the close.—The Dublin College takes of fresh Belladonna Leaves, collected when the plant begins to flower, any convenient quantity. Crush them in a mortar, express the juice, and allow it to stand for twenty-four hours. Pour off the clear liquor, and set it aside for subsequent use; and, having placed the sediment in a calico filter, wash it with an equal bulk of distilled water, and mix the washings with the decanted liquor. When, by the application of a water heat, coagulation has occurred, skim off the coagulated matter, filter the hot liquid through flannel, mix in now the washed sediment, and evaporate to the consistence of a firm extract, by a steam or water bath, constantly stirring, particularly towards the close of the evaporation.)—1 cwt. of fresh belladonna yields from 4 to 6 lbs. of extract. 1 Dose, gr. j to gr. v, cautiously increased. As the strength of the extract is extremely variable, some writers recommend only one-quarter or one-half of a grain to be given at the commencement of its use, and to be repeated three times a day; and the dose to be increased until the well-known effects of the remedy are produced. Mr. Bailey observes that he at first began with one grain, and repeated it every four hours until relief followed; but further experience induced him to commence with three times that quantity, and, if a repetition were necessary, to give it in diminished doses afterwards. Spread upon leather, the extract is frequently used as a plaster to relieve neuralgic and other pains (see Emplastum Belladonnae). Diluted with water to the consistence of cream, it is applied to the eyebrow to produce dilatation of the pupil; or an aqueous solution of the extract is dropped between the lids. Mixed with cord and spermaceti ointment, it is used as a topical anodyne and antispasmodic in various diseases (see Unguentum Belladonnae). A bougie smeared over with the extract and oil is sometimes used with benefit in stricture. 2 A drachm or two of the extract, either alone or in the form of ointment, may be applied to the os uteri to diminish rigidity. In irritation of the bladder, urinary organs, or rectum, clusters holding in solution the extract are sometimes used. Rubbed into the perineum or over the track of the urethra, the extract or ointment is useful in preventing chordee, and alleviating spasm of the neck of the bladder.

[As the fresh leaves of Belladonna are with difficulty procured in the United States, as a substitute for the above extract, the Pharmacopœia directs an extract to be made from the dried leaves by means of diluted alcohol. The formula is, Belladonna, in coarse powder, lbj; Diluted Alcohol Oiv. Moisten first with half a pint of the fluid, and allow to stand for 24 hours. Then transfer to a percolator and displace, driving over the last quantity of fluid with water. Evaporate the solution to the proper consistence. This constitutes the Extractum Belladonnae Alcoholicum, U. S. See a similarly prepared extract from Hyoscyamus.]

1 Brande, Man. of Pharm. 3d edit. p. 401. 

2. EMPLASTRUM BELLADONNE, L. E. D. [U. S.]; Plaster of Belladonna.—(Extract of Belladonna [3], D.); Soap Plaster, of each, 3 iij [Resin Plaster 3 iij, D., 5 iij, E.]. Add the extract to the plaster, melted by the heat of a water-bath, and mix.—[The U. S. P. directs of Resin Plaster 3 iij; Extract of Belladonna 8 iiss.]—Anodyne and antispasmodic. Applied for the relief of neuralgic, rheumatic, and other pains. It is said to relieve the pain of dysmenorrhea when applied to the sacrum. In spreading it, care must be taken not to employ a very hot spatula, or the properties of the extract will be injured.

3. UNGUENTUM BELLADONNE, L. [U. S.]; Ointment of Belladonna.—(Extract of Belladonna 5; Spermaceti Lard 6; [Lard 5; U. S. Mix. ]—A very useful preparation; and may be used as an anodyne and antispasmodic in some of the before-mentioned cases.

4. TINCTURA BELLADONNE, L. [U. S.]; Tinctura Foliorum Belladonnse, D. ; Tincture of Belladonna.—(Belladonna Leaves, dried, 3 iv; Proof Spirit [Diluted Alcohol, U. S.] Oij). Macerate for seven [fourteen, D.] days, and strain.—Dose, m xx to n xl. Mr. Blackett prepared a saturated tincture of belladonna by macerating, for fourteen days, 5 oij of extract of belladonna in 1819 of proof spirit; then straining. The dose of this is m iij or m iiij, gradually increased; in the form of lotion, a drachm of it was added to eight ounces of liquid.

 Succus Belladonna.—The Preserved Juice of Belladonna may be substituted for the tincture. From 2 cwt. of belladonna leaves, evaporating towards the end of June, 16 imperial quarts of juice have been procured.

5. ATROPIA, L.; Atropina; Atropium; Atropine. Symbol At. Formula C₃₄H₅₃NO₅. Eq. Wt. 589. Found in all parts of the plant. Discovered in 1819 by Mr. Brandes. The most improved processes for the preparation of this alkaloid are those of Mein² and Richter. The following is a sketch of Mein's process as modified by Liebig:

Fresh dried and powdered belladonna root is to be exhausted by alcohol, sp. gr. 0.822. To the tincture add slaked lime (in the proportion of one part of lime to 24 parts of dried root). Digest for 24 hours, frequently shaking. Add, drop by drop, sulphuric acid to the filtered liquor till there is a slight excess; then filter again, and distil off rather more than half of the spirit. To the residue add some water, and evaporate the remainder of the alcohol as rapidly as possible, but by a very gentle heat; filter again, and continue the evaporation until the liquid is reduced to the 1-12th part of the weight of the root employed. To the cold liquid add, drop by drop, a concentrated solution of carbonate of potash, to throw down a dark grayish-brown precipitate, taking care not to render the liquid alkaline. In a few hours filter again; add carbonate of potash as long as a precipitate (atropia) is produced; and in from 12 to 24 hours collect the crystallized atropia on a filter, press it between folds of blotting-paper, and dry it.

To purify the dry but impure atropia, make it into a paste with water, and again squeeze between folds of blotting-paper; dry it, and dissolve in five times its weight of alcohol. The filtered liquor is to be decolorized by shaking it with purified animal charcoal, then deprived of the greater part of its alcohol by distillation, and afterwards evaporated by a gentle heat, so as to allow the atropia to crystallize; or draw off half of the spirit, add, gradually, water (3 or 4 parts), which renders the liquid milky, heat to boiling, and allow it to cool slowly; or add to the spirituous solution 6 or 8 times its volume of cold water, which renders the liquid milky, and in from 12 to 24 hours the atropia crystallizes, and is to be dried on blotting-paper.

In this process, the alcohol extracts from the belladonna root a salt of atropia; this is decomposed by the lime, which removes the organic acid and colouring extractive matter. Sulphuric acid is then added, to unite with the disengaged atropia;

² Journ. de Pharm. t. xx. p. 87, 1831; also Thomson's Chemistry of Organic Bodies, p. 273, 1838.
³ Pharm. Central-Blatt fär 1837, p. 513.
for this alkaloid, when free, and especially when in contact with alkalies, readily undergoes decomposition by heat. The solution of sulphate of atropia must be evaporated by a very gentle heat, because the atropia salts, especially in the impure state, easily undergo decomposition. A small quantity of carbonate of potash is necessary, to separate a resinous substance which impedes the crystallization of the atropia. An excess of a concentrated solution of carbonate of potash is required to precipitate, as speedily as possible, the atropia, as by long contact with watery fluids this alkaloid disappears.

Messrs. Bouchardat and Cooper recommend the following mode of preparing atropia: The atropia is to be precipitated by a watery solution of iodine in iodide of potassium, and the ioduretted hydriodate of atropia decomposed by zinc and water. The metallic oxide is separated by means of carbonate of potash, and the alkaloid dissolved in alcohol.

Atropia crystallizes from its concentrated hot, watery, or spirituous solution in white, transparent, silky prisms; from its solution in dilute spirit, in needles like those of sulphate of quinia. It is odourless, and has a very bitter, acrid, somewhat metallic taste. Impure atropia is not crystalline, is more or less coloured, and has an unpleasant odour. One part of atropia requires 200 parts of cold water, or 54 parts of hot water, to dissolve it. It is soluble in 1½ times its weight of cold alcohol, but requires, at ordinary temperatures, 25 parts of ether to dissolve it, or 6 parts of boiling ether.

It reacts on vegetable colours as an alkali, fuses by heat, and at a higher temperature is partly volatilized and partly decomposed. Nitrile acid dissolves it, forming a yellow solution. Cold oil of vitriol dissolves it without colour; but if heat be applied, the mixture acquires a red colour. When heated with a solution of potash or soda, atropia undergoes decomposition, and gives out ammonia.

White, has the shape of prisms, is soluble in water and in spirit. No characters are at present known by which its purity can be certainly indicated, L.

Atropia possesses the property of left-handed circular polarization; but its rotating power is feeble, though it is unaffected by the presence of acids.

A watery solution of a salt of atropia is reddened by tincture of iodine; yields a citron-yellow precipitate with a chloride of gold; a whitish, flocculent precipitate with tincture of nutgalls; and a yellowish-white with chloride of platinum. The sulphate, hydrochlorate, and acetate of atropia are crystalline salts.

Atropia is a most energetic poison. Its effects are similar to, but more powerful than those of belladonna. Dogs are readily poisoned by it; but rabbits are less under its influence. A very minute (imponderable) quantity applied to the eye is sufficient to dilate the pupil. Given to dogs it excites vomiting, dilatation of the pupil, and stupor. On man, the effect is much stronger. One centigramme (about 1-6th of a grain) produces the following symptoms: At first, acceleration of the pulse by eight to twenty strokes; after from fifteen to thirty minutes, an affection of the brain is produced. The first and most constant symptom is dry throat, with difficulty of swallowing. The second is dilatation of pupils, with dimness of sight, also giddiness, noise in the ears, hallucination, delirium, and occasionally strangury; numbness of the limbs, a sensation of formication in the arms, rigidity of the thighs, depression of the pulse. The voice is sometimes weakened; or there may be complete aphonia. The unfavourable symptoms disappear after from twelve to twenty hours.

Atropia has recently been employed medicinally (chiefly as an external agent) as a substitute for belladonna, to which it is considered superior, on account chiefly of the uncertainty of the latter. It is of course much more energetic, and, for external use especially, is much cleaner than the extract. As a topical agent, it has been employed as a mydriatic (see vol. i. p. 245) or dilator of the pupil, by Reisinger, Mr. W. W. Cooper, and Dr. Brooke, in cataract, &c. The last-mentioned writer states that, in a case of glaucoma, he succeeded in causing dilatation of the pupil.

1 Annuaire de Thérapeutique pour 1849.
9 Ibid. January 30, 1847.
9 Lancet, June 8, 1844.
with an ointment of atropia when belladonna failed. As an anaesthetic or anodyne (see vol. i. p. 238), he used the same preparation with success in a painful affection of the face (neuralgia?). — The local pain which atropia produces when used endermically (see vol. i. p. 174) is of very short duration, and is unattended with any ill consequences. Internally, atropia has been employed in hooping-cough, chorea, and some other nervous diseases.

The dose of atropia for internal use is from about 1-30th to 1-6th of a grain. Its employment requires great caution. The safest mode of administration is in solution, on account of the facility with which the dose may be adjusted; but it has also been given, mixed with sugar, in the form of powder; and, mixed with the powder of marshmallow root and honey, in the form of pills. It may be employed endermically (see vol. i. p. 174) in doses of about the $\frac{1}{50}$th of a grain gradually increased to $\frac{1}{4}$th of a grain. For a collyrium, to dilate the pupil, one grain may be dissolved in 400 grs. of water; and a few drops of the solution applied to the eye.

1. *Tinctura Atropiae*; Tincture of Atropine.—Dissolve one grain of atropia in one fluiddrachm of rectified spirit, and then add seven fluiddrachms of distilled water. Dose, from fifteen minimis gradually and cautiously increased to eighty minimis. One drop of this solution, applied to the eye night and morning, was used by Mr. W. W. Cooper to keep up dilatation of the pupil.

2. *Solutio Atropiae Hydrochloratis*; Solution of Muriate of Atropine.—Dissolve one grain of atropia in a fluiddrachm of water acidulated with one minum of hydrochloric acid; then add seven fluiddrachms of water. Dose, from fifteen to eighty minimis.

3. *Unguentum Atropiae*; Ointment of Atropine.—Atropia, five grains; lard, three drachms; attar of roses one drop. Mix.—The size of a pea, to be applied three times a day. Used by Dr. Brookes, with great success, in a painful affection of the face, and to dilate the pupil.

6. *ATROPE SULPHAS*, L.; *Sulphate of Atropia*.—(Dilate Sulphuric Acid $\frac{1}{3}$j; Atropia $\frac{1}{3}$vjjs, or as much as may be sufficient; Distilled Water $\frac{1}{3}$ss. Add gradually to saturation the atropia to the acid mixed with the water. Let the liquor be strained, and evaporate it by a gentle heat that crystals may be formed, L.)—The College observes that this salt is intended for external use only. It is employed in the form of solution, prepared by dissolving one or two grains in a fluidounce of water, to produce dilatation of the pupil.

### 173. DATURA STRAMONIUM.—COMMON THORN-APPLE.

*Sex. Syst.* Pentandria, Monogynia.

*(Folium et Semen, L. [U.S.].—Herb, E.—The seed, D.)*

**History.**—This plant, being a native of Greece, must have been known to the ancient Greek botanists; though it is impossible now to identify it, with certainty, with any of the plants described by them. It appears, however, to agree tolerably well with the σπισύνος μανίξος of Theophrastus. Datura Stramonium is mentioned by Fuchs in 1542.

**Botany. Gen. Char.**—Calyx tubular, frequently angular, 5-cleft at the apex, or longitudinally slit, falling off by a circular horizontal incision above the peltate base. Corolla hypogynous, funnel-shaped, with a large, spreading, plaited 5—10-toothed limb. Stamens 5, inserted into the tube of the corolla, inclosed or somewhat exserted; anthers dehiscing longitudinally. Ovary incompletely 4-celled, the alternate dissepiment being lost above the middle, the other one complete; the middle on both sides placentaferous. Style simple; stigma bilamellate. Capsule ovate or sub-globose, muricate or aculeate, rarely smooth, half 4-celled, incompletely 4-valved at the septa. Seeds numerous, reniform. Embryo within fleshy albumen, subperipherical, arched (Endlicher).

---

Common Thornapple:—Description; Composition.

**Sp. Char.—Annual.** Leaves ovate, angulate-dentate, wedge-shaped at the base, rather smooth. Fruit ovate, erect, densely spiny. Calyx equal to the diameter of the limb of the corolla (Nees).

A bushy, smooth, fetid herb. Stem much branched, forked, spreading, leafy. Leaves from the forks of the stem, large, unequal at the base, variously and acutely sinuated and toothed, simple ribbed, veiny, of a dull green. Flowers axillary, erect, white, sweet-scented, especially at night, about 3 inches long. Fruit as big as a walnut, in its outer coat very prickly. Seeds black (Smith).

**Hab.**—Indigenous; in waste ground and on dunghills. Annual. Flowers in July.

Several other species of *Datura* are used in the East.

**Datura peregrina**, Linn.—Annual. Leaves ovate, angulate-dentate, cuneiform at the base, glaucous. Fruit ovate, erect, pyramidal spiny. Calyx longer than the diameter of the limb of the corolla (Nees).—Nepal. In 1802, General Gent introduced this species into this country as a remedy for asthma. It was employed by smoking it.¹ Waitz² says that half an upright capsule acted violently on a girl.

**Datura fastuosa**, Mill.—Annual. Leaves ovate, acuminate, repandly-toothed, unequal at the base, and are, as well as the stem, somewhat downy. Fruit nodding, tuberculated (Nees).—East Indies. In 1811, Dr. Christie³ directed attention to this species. Mr. Skipton⁴ administered the decoction of the root of this plant; and Dr. Adams⁵ used a tincture (prepared as tincture of digitalis, Ph. L.).

**Datura pilula**, Linn.—Annual. Leaves cordate-ovate, angulate dentate, unequal at the base, smooth. Fruit ovate, erect, spiny (Nees).—Schurbath⁶ gave half a pound of the bruised leaves of this species to a horse without effect; twenty-one ounces of the half-ripe fruit caused dejection, increased secretion, and loss of appetite. Cigars for the use of asthmatics are made of this species.

**Datura alba**, Roxb.; *D. Metel*, Roxb.—Annual. Leaves ovate, acuminate, repandly-dentate, unequal at the base, rather smooth. Fruit nodding, spiny.—East Indies. Both this and the preceding species have been employed, especially in the East, to cause intoxication for criminal and licentious purposes.⁷

**Description.—**The herb (herba stramonii) should be collected when the plant is in flower. The leaves (folia stramonii) are then to be carefully dried. In the fresh state their odour, when bruised, is unpleasant and narcotic; their taste nauseous and bitter. By drying, the odour is lost, but the bitter taste remains. The seeds (semina stramonii) are small, compressed, kidney-shaped, roughish, dark-brown or blackish, dull, and odourless; they have a bitter, nauseous, somewhat acid taste.

**Composition.—**The herb was analyzed, in 1815, by Promnitz;⁸ the seeds in 1820, by Brandes.⁹

| Fresh herb of stramonium | 100.00 | Seeds of stramonium | 100.00 |

1. *Datura* (Daturaria, or Daturium) — Formula, C₉H₅NO₄. A vegetable alkali said to exist in stramonium. The properties assigned to it by Geiger and Hesse¹⁰ are the following: It crys-

⁶ Skipton. ¹³ Ibid.

VOL. II.—31
tallizes in colourless, odourless, brilliant prisms, which have at first a bitterish, then a tobacco-like flavour. It requires 280 parts of cold, or 72 parts of boiling water to dissolve it; it is very soluble in alcohol, less so in ether. In most of its properties it agrees with hyoscyamin. It strongly dilates the pupil, and has a poisonous action on animals. Dr. Avon Plantu has recently submitted atropia and daturia to comparative examination, and declares that they are identical in composition and chemical properties.

2. EMPYREUMATIC OIL OF STRAMONIUM (Pyrodatura?).—Reminisces tar and the aqueous fluid which distils along with its acid. This arises from the woody part of the plant having been employed. The oil itself does not differ, in its physical and chemical properties, from the empyreumatic oil of foxglove before (see ante, p. 457) described.2

PHYSIOLOGICAL EFFECTS. a. On Vegetables.—A branch of stramonium was killed by immersing it in a watery solution of the extract of its own species.3

b. On Animals generally.—Its influence on herbivorous animals is much less than that on man. Five ounces of the expressed juice given to the horse, cause merely slight drowsiness and gaping.4 Two pounds and a half of the seeds killed a horse in fifty-two hours.5 From Orfila’s experiments with it on dogs,6 it does not appear to act powerfully as a local irritant. Its effects were very similar to those caused by belladonna.

g. On Man.—The symptoms produced on man closely resemble those of belladonna. In small but gradually increased doses, it diminishes sensibility, and thereby frequently alleviates pain. It does not usually affect the pulse; it slightly and temporarily affects the pupil, and has no tendency to cause constipation, but rather relaxation. Though it allays pain, it does not usually produce sleep. In larger doses, it causes thirst, dryness of the throat, nausea, giddiness, nervous agitation, dilatation of the pupil, obscuration of vision, headache, disturbance of the cerebral functions, perspiration, occasional relaxation of bowels, and in some cases diuresis. It has no direct tendency to induce sleep, and hence it cannot be called soporific. But indirectly, by alleviating pain, and thereby producing serenity and ease, it often disposes to sleep. In fatal doses, the leading symptoms are flushed countenance, delirium (usually maniacal), dilatation of the pupil, dryness of the throat, loss of voice, difficulty of deglutition, convulsions, and, in some cases, palsy. A very interesting fatal case of poisoning by 100 seeds is related by Mr. Duffin.7 The patient (his own child) was two years and a quarter old. In addition to the preceding symptoms, there were a hot, perspiring skin, flushed, slightly swollen face, pulse almost imperceptible, but, as far as could be felt, it was natural in regard to frequency, and coldness of the inferior extremities. The anterior fontanelle was neither tense, hot, nor in the slightest degree raised by the cerebral pulsations; so that there did not seem to be any active determination of blood to the brain. During the continuance of the coma the pulse became extremely rapid. Death occurred twenty-four hours after swallowing the seeds.

Vogt8 says stramonium is probably distinguished from belladonna by the following peculiarities:

1. Its effects are more similar to those of acrid vegetables, especially of Helloborus.

2. It operates more strongly, but more in the manner of the acrid substances, on the nervous system, especially on the central organs, viz., the ganglia, spinal cord, and brain.

3. Its secondary effects on the irritable system are not so marked; for most observers have failed to detect any alteration of pulse, and a slow pulse is more frequently mentioned than a quick one.

4. It operates on the organic life more strongly. It more strongly and directly promotes all the secretions, especially the secretion of the skin.

5. Marcel8 and Begbie9 have inferred, from numerous observations, that it possesses an ana
dyne property, which it frequently evinces where opium and belladonna fail.

USES.—A more extended experience of this plant is requisite to enable us to speak with much confidence of its employment. The similarity of its effects with

4 Moiroud, Pharm. Vét. p. 350
7 Trans. of the Med. Soc. Edinb. vol. i.
those of belladonna would lead us to expect a similarity of uses. Like the last-mentioned plant, it has been successfully employed to diminish sensibility, and thereby to relieve external pain. Some of the other uses made of it require a more impartial examination ere we can form any just estimate of their value. The indications and contraindications for its employment are probably similar to those of belladonna. In persons disposed to apoplexy it is a very dangerous remedy.

In neuralgia (tic douloureux, sciatica, &c.), it has been employed with considerable success by Lentin,² Marect,³ and Beggie.⁴ It was given internally in the form of extract. Its external application has scarcely been tried. In rheumatism, it has frequently proved serviceable from its anodyne qualities.⁵ In enterodynia (that is, spasmodic pain of the bowels unconnected with inflammatory action or the presence of irritating substances), Dr. Elliotson⁶ found it most successful.

In some cases of spasmodic asthma, smoking the herb has given at least temporary relief;⁷ but the practice requires very great caution, as it has proved highly injurious, and in some instances fatal. Dr. Bree⁸ tried it in 82 asthmatic cases; in 58 of these it had no permanent effect, and in the remaining 24 it acted injuriously. General Gent, who was instrumental in introducing the practice, fell a victim to it.⁹ Aggravation of the dyspepsia, paralytic tremblings, epilepsy, headache, and apoplexy, are some of the evils said to have been induced in the cases above referred to. In persons disposed to head affections, and in aged persons, it is, therefore, a highly dangerous practice.

The diseases in which stramonium has been principally used are mania and epilepsy. Bayle⁹ has collected from the works of Storek, Schemalz, Razous, Reef, Meyer, Odhelius, Duronde, Marec, Bergius, Greding, Schneider, Bernard, and Amelung, fifty-five cases of the first, and forty-five of the latter malady, treated by stramonium; in both diseases, a considerable majority of cases are said to have been either cured or relieved by it. Without denying the occasional benefit of stramonium in these diseases, I believe the cases in which it is serviceable to be very rare, while those in which it is calculated to be injurious are very common. Dr. Cullen¹⁰ observes, that he has no doubt that narcotics may be a remedy for certain cases of mania and epilepsy; but he very justly adds, "I have not, and I doubt if any other person has learned to distinguish the cases to which such remedies are properly adapted."

Stramonium has been used to dilate the pupil and to diminish the sensibility of the retina to the influence of light; but for both of these purposes belladonna is preferred by British oculists. Wendt¹¹ used it to lessen venereal excitement, as in nymphomania. An ointment (made with ½ of the powdered leaves, and ½iv of lard) has been used as an anodyne application to irritable ulcers and to painful hemorrhoids. The application of the leaves to burns has been attended with dangerous results.¹²

ADMINISTRATION.—The dose of the powdered leaves is one grain; of the seeds half a grain. These doses are to be repeated twice or thrice a day, and to be gradually increased until some obvious effect is produced.

1. EXTRACTUM STRAMONII, L. E.; Extract of Thornapple [Extractum Stramonii Seminat, U. S.].—(Thornapple Seeds 3xv; Boiling Distilled Water Cong. j. Mace-rate for four hours in a vessel slightly covered, near the fire; afterwards take out the seeds, and bruise them in a stone mortar; return them, when bruised, to the liquor. Then boil down to four pints, and strain the liquor while hot. Lastly, evaporate to a proper consistence, L. The directions of the Edinburgh College are as follows:

¹ Hayle, Bibl. Théât. t. ii.
³ See the reports of Kirckhoff, Engelhart, Van-Nuflal, and Amelung, in Bayle, op. cit.; also Eberle, Mat. Med.
⁷ Ibid. vol. xxvi. p. 40.
⁸ Ibid. vol. xxvi. p. 40.
¹⁰ Mat. Med.
Take of the seeds of stramonium, any convenient quantity; grind them well in a coffee-mill. Rub the powder into a thick mass with proof spirit; put the pulp into a percolator, and transmit proof spirit till it passes colourless; distil off the spirit, and evaporate what remains in the vapour-bath to a proper consistence.)—Of the above modes of preparation, that of the Edinburgh College is doubtless the best, as yielding a more efficient preparation. [The U. S. Pharr. directs Stramonium Seed, in powder, th.; Diluted Alcohol q. s. Displace with the alcohol, and evaporate to the proper consistence.] The product, according to the London and Dublin process, is about 12 per cent. 4 Reclus states, that 16 oz. of the seeds yield 2 oz. 2 dr. by maceration in dilute alcohol; this is about 14 per cent. The dose of extract of stramonium, at the commencement, is about a quarter of a grain, which should be gradually increased until some obvious effect is produced.

[2. EXTRACTUM STRAMONII FOLIORUM, U. S.; Extract of Stramonium Leaves.— (Take of Stramonium Leaves a pound. Bruise them in a stone mortar, sprinkling on them a little water; then express the juice, and, having heated it to the boiling point, strain and evaporate to the proper consistence.)—This affords a fine green extract, endowed with the odour and properties of the plant. The dose is from gr. i to grs. v.]

3. TINCTURA STRAMONII, D. [U. S.];—Tincture of Thornapple.—(Stramonium Seeds, bruised, 3v 3i; U. S.;) Proof Spirit Ojij. Macerate for fourteen days, and filter through paper.)—Dose, m.x to m.xx twice or thrice a day, gradually increased until it occasions some obvious effect on the system. This preparation is applicable to all the cases for which stramonium is used.

[4. UNGUENTUM STRAMONII, U. S.; Ointment of Stramonium.—(Take of fresh Stramonium Leaves, cut into pieces, a pound; Lard three pounds; Yellow Wax half a pound. Boil the stramonium leaves in the lard until they become friable; then strain through linen; lastly, add the wax, previously melted, and stir them until they are cold.)—This ointment is used for the same purposes as the belladonna ointment.]

Antidotes.—The same as for belladonna.

174. NICOTIANA TABACUM.—VIRGINIAN TOBACCO.

Sex. Syst. Pentandria, Monogynia.

(Folium, L.—Leaves, E. D.)

History.—The inhalation of the fumes of burning vegetable substances, both for causing inebriation and for medicinal purposes, seems to have been very anciently practised. Herodotus 3 tells us that the Babylonians and Scythians intoxicated themselves by this means; and both Dioscorides 4 and Pliny 5 speak of the efficacy of smoking Tussilago in obstinate cough.

Humboldt 6 says that the tobacco plant has been cultivated, from time immemorial, by the natives of Oronoko. It does not appear, however, to have been known to Europeans prior to the discovery of America; though it is not improbable that the Asiatics were acquainted with it long before that time, as Pallas, Rumphius, and Loureiro have supposed. But it is not probable, I think, that the Europeans learned the use of it from the Asiatics, as Ulloa has endeavoured to show.

When Columbus and his followers arrived at Cuba, in 1492, they, for the first time, beheld the custom of smoking cigars. 7 Hernandez de Toledo introduced the plant into Spain and Portugal; and, from the latter place, Joan Nicot sent the

1 Becker, Observ. on the Dublin Pharm. 2 United States Dispensatory.
seeds or the plant to France, about 1559—60. In 1586, on the return of Sir Francis Drake, with the colonists, from Virginia, the practice of smoking was introduced into England; and, being adopted by Sir Walter Raleigh and other couriers, soon became common.

Various attempts, by writings, imposts, or bodily punishments, were made in Europe to restrict or put down its use. It is said that upwards of a hundred volumes were written to condemn its employment; and not the least curious of these is the celebrated Counterblast to Tobacco of James I. Despite, and partly, perhaps, as a consequence of these attempts, the use of tobacco rapidly spread, and is now universal throughout the world.

The generic appellation Nicotiana is obviously derived from Nicot, the name of an individual above referred to. The origin of the specific name Tabacum is less satisfactorily ascertained. It is probable, however, that the word is derived from tabac, an instrument used by the natives of America in smoking this herb; though some derive it from Tobago, others from Tabasco, a town in New Spain.

**BOTANY. Gen. Char.** — *Calyx* tubular-campanulate, half 5-leaf. *Corolla* hypogynous, funnel-shaped or hypocrateriform; limb plaited, 5-lobed. *Stamens* 5, inserted on the tube of the corolla, inclosed, of equal length; *anthers* deliscing longitudinally. *Ovary* bilocular; placenta adnate to the dorsal dissepiment; ovules numerous; *style* simple; *stigma* capitate. *Capsule* covered by the persistent calyx, bilocular, septicidal-bivalved at the apex; the valves ultimately bifid, retaining the separated placenta. *Seeds* many, small; the embryo slightly arched, in the axis of fleshy albumen (Endlicher).

**Sp. Char.** — *Stem* herbaceous. *Leaves* sessile (the lower ones decurrent), oblong-lanceolate, acuminate. Throat of the corolla inflated-ventricose; the segments of the limb acuminate (Nees).

**Hab.** — America. Extensively cultivated in most parts of the world, especially in the United States of America. Virginia is the most celebrated for its culture. North of Maryland the plant is rarely seen. In England, the cultivation is restricted; not more than half a pole being allowed "in a physic or university garden, or in any private garden for physic or chirurgery."

This is the only species employed in medicine; but the tobacco used for smoking, chewing, and snuff, is derived from several species, the most important of which are the following:—

1. **N. Tabacum**, Linn.; **Common or Virginia Tobacco**. — Of this species several varieties are cultivated. The Virginian and most other sorts of tobacco imported from the United States of America, as also Colombian tobacco, are obtained from it.

2. **N. latissima**, Miller; **N. macrophylla**, Sprengel; **Large-leaved or Oronoko Tobacco**. — This species is very closely allied to, if indeed it be not a variety of, the preceding species. Nees describes the leaves as being more erect or horizontal than those of N. Tabacum, which droop somewhat, and are thicker and more strongly ribbed. Moreover, the lateral nerves of the mid-

rib of N. latissima proceed, he says, at right angles; whereas those of N. Tabacum are given off at an acute angle.1 Furthermore, the flowers of N. latissima form a dense contracted panicle; whereas those of N. Tabacum form a loose spreading one.

This species, like the preceding, has varieties, with broader or smaller, shorter or longer, sessile or stalked leaves. To the latter variety probably belong N. fruticosa, Linn., and N. chiness, Fischer.

According to Mr. G. Don,2 this species probably yields the large Havana cigars.

3. N. Rustica, Linn.; Common Green Tobacco.—Stem herbaceous, terete. Leaves petiolate, ovate, quite entire. Tube of the corolla cylindrical, longer than the calyx; segments of the limb roundish obtuse.—Corolla greenish-yellow.—Indigenous in America; grows wild in Europe, Asia, and Africa. It grows quicker, ripens earlier, and is more hardy than N. Tabacum; and hence it is frequently cultivated in gardens in England, and in several other parts of the world. It is used by peasants as a substitute for the Virginian sort, and for gardeners for the destruction of insects. Nees says that, in smoking, it may be readily distinguished by a peculiar violet odour. Parkinson3 says that, though it is a milder tobacco,4 yet he has known Sir W. Raleigh, when prisoner in the tower, prefer it to make good tobacco.—It yields the tobacco of Salonica (the ancient Thessalonica), and probably also that of Latakia (Laodicea), which is so much esteemed. The tobacco called Turkish, grown on the coasts of the Mediterranean, and highly valued in India, is the produce of this species.

4. N. Persica, Lindl., Bot. Reg. 1699.—Native of Persia. Yields the celebrated Shiraz or Persian tobacco.5

5. N. Repanda, Willd.—Native of Cuba, near Havana. The small Havana cigars, or Queen's, are said to be made of this species.

6. N. quadrivalvis, Parsh.—Cultivated and spontaneous on the Missouri; principally among the Mandan and Ricara nations.—The tobacco prepared from it is excellent. The most delicate is prepared by the Indians from the dried flowers.

7. N. Nana, Lindl., Bot. Reg. t. 833.—Rocky mountains of North America. The Indians are said to prepare the finest of their tobacco from the leaves of this species.

8. N. multivalvis, Lindl., Bot. Reg. t. 1057.—Cultivated by the Indians who inhabit the banks of the Columbia for tobacco, for which purpose the calyx, which is very fetid, is selected in preference to any other part.

CULTURE.—In Virginia and Maryland, the seeds are thickly sown in beds of finely-prepared earth. When the young plants have five or six leaves, exclusive of the seminal leaves, they are transplanted into fields during the month of May, and set three or four feet apart, in rows. During the whole period of growth the crop requires constant attention; and to promote the development of leaves, the tops are pinched off, by which the formation of flowers and seeds is prevented. The harvest is in August. The ripe plants are cut off above their roots, dried under cover, stripped of their leaves, tied in bundles, packed in hogsheads, &c.6

DESCRIPTION.—In commerce, two states of tobacco are distinguished—in the one it is called unmanufactured or leaf tobacco, in the other it is termed manufactured tobacco.

1. Unmanufactured or Leaf Tobacco (Folia Nicotianæ).—Tobacco in this state consists of dried leaves, which have a brownish colour, a strong narcotic but peculiar odour, and a bitter nauseous taste. The darker-coloured sorts are the strongest. For medicinal purposes, Virginian tobacco in leaf (folia tabaci) should be employed.

In trade, various sorts of unmanufactured or leaf tobacco are met with, and are distinguished by the name of the country from which they are imported into the United Kingdom. The differences between them depend on the species or variety of plant cultivated, on the soil and climate, and on the mode of curing.

1. United States Leaf Tobacco.—This constitutes by far the greater proportion of unmanufactured tobacco imported into the United Kingdom. In 1843, no less than 41,038,597 lbs. were imported.

1 Nees says that by this character several of the commercial sorts of tobacco may be recognized. By himself and other German writers this species is called "Maryland tobacco," but I find that, though the lateral nerves of the Maryland tobacco of British commerce are given off at a less acute angle than those of the Virginian tobacco, I cannot find any that proceed at a right angle.

3 Theatrum Botanicum, p. 712, 1610.

4 Seidlécher (Medicinal-Pflanzen, p. 385, 1842) declares that it is more stupefying than other species of Nicotiana.

5 Loudon's Encycl. of Agricult.; Carter, Treatise on the Cult. of the Tobacco Plant, 1779.

6 For a notice of the cultivation of Shiraz tobacco, see a paper by Dr. Rüach, in the Trans. of the Horticultural Society, 2d series, vol. 1, p. 265, 1855.
Several kinds, named from the States where respectively grown, are distinguished in trade; they are as follows:—

The **Virginia** is one of the strongest kinds, and is, therefore, not fit for cigars, but is adapted for pipes and snuff, and for medicinal use. It is imported in leaves or heads contained in hogsheads. Its colour is deep mottled brown; the leaves feel unctuous. The **Maryland** is paler, yellower, weaker, and adapted for smoking; the *pale cinnamon* is the best, the *scuros* the commonest. The **Kentucky** is intermediate between the two preceding; it is paler and weaker than the **Virginia**. The **Carolina** is less frequently met with, and is of inferior quality. The **Missouri** and the **Ohio** are other sorts imported from the United States.

2. **Cuba Leaf Tobacco.**—In 1843, 494,954 lbs. of leaf tobacco were imported from the island of Cuba. The **Havana** sort is most esteemed for smoking; its colour is yellowish-brown; its odour is musky or spicy. It is imported in heads. The **Cuba** is an excellent kind; it is darker than the **Havana**. Both these kinds, as well as the **Colombian**, are remarkable for the light yellow spots on the leaves.

3. **St. Domingo Leaf Tobacco.**—In 1843, 93,114 lbs. of leaf tobacco were imported from St. Domingo (Hayti). It comes over in leaves, and is deficient in flavour.

4. **Porto Rico Leaf Tobacco.**—Small quantities of tobacco in rolls are sometimes imported from this island. In quality, this sort is allied to the **Virgina**.

5. **Colombian Leaf Tobacco.**—In 1843, 1,565,206 lbs. of unmanufactured tobacco were imported from Colombia. Three commercial sorts are brought from that country. Like the **Cuba** sorts, the leaves are marked with light yellow spots. The **Colombian** is imported in heads and leaves, and is much esteemed for cigars, for which it is more used than any other kind. It is dark-brown, but not mottled like the **Virginian**. The **Virgina** is brought over in rolls and in hands. It is a mild tobacco, suitable for smoking only. The third sort imported from Colombia is that called *Cumanan*. *Orinoco* comes over in leaves.

6. **Brazilian Leaf Tobacco.**—In 1843, 128,329 lbs. of unmanufactured tobacco were imported from the Brazil.

7. **Dutch or Amersfoort Leaf Tobacco.**—In 1843, 55,686 lbs. of unmanufactured tobacco were imported from Holland. Dutch tobacco is very mild, and deficient in flavour. The darker kind is the strongest, and is much esteemed for snuff; while the lighter and weaker kind is employed in the manufacture of the commonest cigars.

8. **Levant Leaf Tobacco.**—**Turkey** tobacco is pale and yellowish. It occurs in small, short, broad leaves, and is the produce of N. Rustica. It is a weak tobacco, and is cut for smoking. *Latakkaia* (Laodicea) is an esteemed Syrian tobacco, the produce of the same species. *Salonica* is also yielded by N. Rustica. *Persian or Shiraz* tobacco is delicate and fragrant. It is the produce of N. Persica.

9. **East Indian Leaf Tobacco.**—**East Indian** tobacco has never obtained a high repute, doubtless from inattention to its culture and curing. In 1843, 59,158 lbs. were imported.

10. **Manilla Leaf Tobacco.**—In 1843, 2,638 lbs. of unmanufactured tobacco were imported from the Philippine Islands. *Manilla* tobacco is dark coloured, and is much esteemed for cheroots.

2. **Manufactured Tobacco.**—Under this head are included the different forms of tobacco prepared for chewing and smoking, and for taking as snuff.

1. **Chewing and Smoking Tobaccos.**—Manufacturers distinguish chewing tobaccos and those used in pipes into two kinds, called respectively cut and roll tobacco. For smoking in the pipe, cut tobacco is principally used in England; the roll in Scotland and Ireland. Cigars and cheroots form a third kind.

1. **Cut Tobaccos.**—These sorts are manufactured by moistening and compressing the leaves of tobacco, and cutting the compressed mass, with knife-edged chopping stumps, into small pieces or shreds varying from 16 to 100 cuts in the inch. By the addition of water (or the *liquor*), cut tobacco increases in weight from 8 to 10 per cent., according to circumstances. Shag tobacco is chiefly prepared from the **Virginian** and **Kentucky** sorts deprived of their stalks or midrills. *Returned* is a lighter coloured and milder smoking tobacco. It derives its name from its being formerly prepared by returning shag for recutting. *Bird's-eye* is prepared like shag, with the exception that it contains the midrills of the leaves, the slices of which have been compared to the eyes of birds. **Maryland** is another kind of cut tobacco. **Canaster** or **Kanaster** is a favourite kind. It received its name from *canaster* (a Spanish word, signifying a basket).

---

1 Sir H. Sloane (Jamaica, vol. i. p. lxxi.) says that the tobacco "from Nuevo Reyno de Granada ( corruptly called Verinias or Tabaco de Verina) is reckoned the best."  
3 It is said that tobaconists employ, in the preparation of tobacco, a solution of sea-salt (sp. gr. 1.107), which is termed the *sauce* or *liquor*, but I am assured that this is not generally the case. This liquor, if it is further steamed, is sometimes coloured by treacle or liquorice.  
4 If returns of tobacco are the small pieces of broken leaf, and the dust and siftings, produced in the various processes of manufacture.  
5 (Tobacco Report.)
VEGETABLES.—NAT. ORD. SOLANACEÆ.

because it was imported in baskets. It is prepared from Varinas tobacco. Orinoco, Turkey, Persian, and Varinas, are also cut tobaccos.

2. SPEN, ROLL, OR TWIST TOBACCO.—These are prepared by twisting tobacco into a kind of rope, which is moistened with liquor,¹ and is usually made up into cylindrical or barrel-shaped rolls or sticks, which are subjected to pressure before they are considered fit for sale. Pigtail, Negro-head, Bagie, Allot, Cavendish, and Irish twist, are roll tobaccos for chewing and smoking. During its manufacture, roll tobacco increases in weight from 15 to 25 per cent.

3. CIGARS AND CHEROOTS.—These are small rolls of tobacco permeable to air and adapted for smoking. Cigars were originally derived from the New World. They are distinguished from cheroots by their pointed extremity, called the curl or twist. The Havana cigars are in great request by smokers. Cigars, however, are extensively made in London. Cheroots were originally derived from the East. They are characterized by their truncated extremities. Manilla cheroots are much valued by smokers. Cheroots, however, like cigars, are extensively manufactured in London.

2. SNUFFS.—In the manufacture of snuff, tobacco, cut in small pieces, is first fermented by placing it in heaps and sprinkling it with water or a solution of salt; the latter prevents the tobacco becoming mouldy. The heaps soon become hot and evolve ammonia. The extent to which this process is allowed to proceed varies with different kinds of snuff. The usual time is two or three months, seldom less than one month. The fermented tobacco is then ground in mills, or powdered with a kind of pestle and mortar. The Scotch and Irish are prepared for the most part from the midrifs; the Strasburg, French, and Russian snuffs from the soft part of the leaves. The siftings, sometimes termed thirds, are usually reground. Sal ammonia is occasionally added to snuffs.

The theory of the tobacco fermentation is imperfectly known. Decomposition probably first commences in the albuminous constituent, which yields carbonate of ammonia. The organic salts (malates) next suffer change, and are converted into carbonates. The lignin is the last to decompose; it becomes friable, yields ulmic acid, which colours the tobacco, and a little acetic acid. A portion (perhaps two-thirds) of the nicotine disappears during the process, being either decomposed or volitized by the aid of the carbonate of ammonia. Moreover, while in the fresh plant the nicotine is found in the state of a salt (malate!) insoluble in ether, in the fermented plant it is found chiefly in the state of acetate or subacetate soluble in ether.

The immense varieties of snuffs found in the shops are reducible to two kinds—dry and moist snuffs.

a. Dry Snuffs.—These derive their characteristic property from being dried at a high temperature previous to being ground. Scotch, Irish, and Welsh, are well-known high-dried snuffs. The latter frequently contains lime, the particles of which may be usually distinguished by the naked eye; hence its desiccatting effect on the pituitary membrane.² Spanish snuff is also a dry snuff.

Brown Scotch is Scotch snuff moistened after being ground.

b. Moist Snuffs; Rappees.—These are snuffs which have been prepared by grinding the tobacco to powder in a moist state. It is sometimes said that pearlash is added to these snuffs to keep them moist, but several respectable manufacturers assure me this is not usual. The rappees of the shops may be divided into three classes: Simple Rappees—as Brown, Black, Cuba, Carotte, and Molangero; Mixed Rappees—as Hardham’s Genuine No. 37; and Scented Rappees—as Prince’s Mixture and Princeza, &c.

COMPOSITION.—The juice of the fresh leaves of tobacco was analyzed in 1809 by Vaquelin.³ Subsequently, this chemist analyzed manufactured tobacco.⁴ In 1821, Hermbstäti discovered nicotianin. In 1827, the leaves were analyzed by Posselt and Reinmann,⁵ and in 1831 by Dr. Conwell.⁶ In 1845, Messrs. Brande and Cooper⁷ made a series of experiments to ascertain the proportion of soluble and insoluble matters in eight samples of tobacco.

¹ Water and oil are alone allowed by law to be used in the manufacture of roll tobacco; but sugar, molasses, and liqueurs are frequently employed.
² The Act of Parliament allows lime-water to be used in the manufacture of Irish and Welsh snuffs; but Mr. Foot (Tobacco Report) states that the Lundyfoot or "high-toned snuff" is made of the stalks and leaves of tobacco and water (which latter is afterwards got rid of by drying) without lime.
⁴ Schweiger’s Journ. fär Chem. xxxi. 441.
VIRGINIAN TOBACCO:—COMPOSITION.

**Vauquelin's Analysis.**

An acid volatile principle (nicotina).
Albumen.
Reducible, soluble in alcohol and water.
Acetic acid.
Supermalate of lime.
Chlorophyll.
Nitrate of potash and chlorides of potassium.
Salt ammoniac.
Water.

**Posse1t and Reinmann's Analysis.**

Nicotina ........................................ 0.06
Concrete volatile oil (nicotianin) ......... 0.01
Bitter extractive ............................ 2.87
Gum with malate of lime .................. 1.74
Chlorophyll ..................................... 0.287
Albumen and gluten ......................... 1.308
Malic acid ................................... 0.21
Lignin and a trace of starch .......... 4.069
Salts (sulphate, nitrate, and malate of potash, chlorides of potassium, phosphate and malate of lime, and malate of ammonia) ...... 0.734
Silica ........................................ 0.068
Water .......................................... 88.250

Fresh leaves of tobacco .......... 100.000

**Conwell's Analysis.**

Gum.
Mucilage soluble in both water and alcohol.
Tannin.
Gallic acid.
Chlorophyll.
Green pelluculent matter, soluble in boiling water.
Yellow matter, having the colour, taste, and poisonous properties of tobacco.

1. NICOTINA (Nicotine). Symbol Ni. Formula C{H}{N}{O}_2. Enl. Wt. 162.—Exists not only in the leaves (both fresh and fermented), but also in the root and in the seeds, as well as in the smoke of tobacco. It is obtained by digesting an aqueous extract of the leaves in rectified spirit, which takes up the nicotine salts. The decanted tincture is to be concentrated, mixed with a solution of potash, and briskly shook with ether, which dissolves the nicotine set free by the potash. To purify the alkaloid, add gradually to its solution oxalate acid in powder; oxalate of nicotine, insoluble in ether, forms, at the bottom of the vessel, a syrupy layer, which is to be repeatedly shaken with pure ether. The nicotine may be separated by potash and ether, as before. The ethereal solution is to be distilled in a salt-water bath, then transferred to a retort, through which a current of dry hydrogen circulates; exposed to a temperature of 284° F. in an oil bath, in order to entirely get rid of the water, ether, and ammonia; lastly, the temperature is to be raised to 350°, when the nicotine distills over drop by drop. From 28 lbs. of Virginia tobacco, at least 4 per cent. of nicotine can be obtained by this process.

Nicotina is a colourless liquid alkaloid, with an acrid odour and an acrid burning taste. Its density is 1.024. It restores the blue colour of reddened litmus, and renders turmeric brown. It does not solidify at 14° F.; it boils at 482° F., and at the same time undergoes decomposition. By exposure to the air it becomes brown and thick. It is readily combustible with the aid of a wick. It is soluble in water, ether, alcohol, and the oils (fixed and volatile). It combines with acids, and forms very deliquescent salts; the sulphate, phosphate, oxalate, and tartrate, are crystallizable; the acetate is not. A dilute aqueous solution of nicotine yields a white fuscous precipitate (double chloride) with a solution of bichloride of mercury, and a yellow granular precipitate with chloride of platinum.

Nicotina is an energetic poison, almost equalizing in activity hydrocyanic acid. 3

The amount of nicotine in leaf or manufactured tobacco may be estimated by Schloeg's process. 4

Exhaust two draughts of tobacco by ammoniacal ether in a continuous distillatory apparatus, expel the ammoniacal gas from the nicotine solution by boiling, then decant, and after the evaporation of the ether, estimate the amount of nicotine in the residue by the quantity of diluted sulphuric acid of known strength required to saturate it.

The following are the amounts found in various French and American tobaccos:

3 An interesting case of poisoning by nicotine has recently occurred in Belgium. See Orfila, Rept. du Pharmacie, June, 1851.
4 Chemical Gazette, vol. v, p. 41, 1847.
490 VEGETABLES.—NAT. ORD. SOLANACEAE.

2. **Acids of Tobacco.**—Tobacco is very rich in malic acid; it also contains citric and phosphoric acids, and according to M. Barral, a peculiar acid which he terms *nicotianic acid.*

3. **Concrete Volatile Oil of Tobacco** (*Nicotianin, Hermbsäalt; Tobacco-camphor, Gmelin*). Obtained by submitting tobacco leaves, with water, to distillation. Six pounds of the leaves yielded eleven grains of oil, which swims on the surface of the liquor. This oil is solid, has the odour of tobacco, and a bitter taste. It is volatile, insoluble in water and the dilute acids, but soluble in ether and caustic potash. According to Landerer, 1 fresh tobacco leaves yield no nicotianin, which, therefore, would appear to be developed by the drying of the leaves under the influence of air and water. Nicotianin excites, in the tongue and throat, a sensation similar to that caused by tobacco smoke. Hermbsäalt swallowed a grain of it, and experienced, soon after, giddiness, nausea, and inclination to vomit. Applied to the nose it causes sneezing.

4. **Ashes of Tobacco.**—Tobacco yields a very large amount of ashes, both the quantity and quality of which vary considerably. The ashes obtained from the leaves (including the rib) vary from 17 to 27 per cent. 2

5. **Tobacco Smoke.**—The constituents of tobacco smoke, according to Raab, 3 are much carbonate of ammonia, acetate of ammonia, nicotianin, empyreumatic oil, carbonaceous matter (soot), moisture and several gases. Unverdorben obtained, 4 by the dry distillation of tobacco, water, oil, and resin. These products consisted of a volatile oil, an oleaginous acid, an empyreumatic acid, (Brandshure), resin, traces of a powder insoluble in potash and acids, a small quantity of odorin, a base soluble in water (nicotin?), fuscin, red matter soluble in acids, and two extractive matters, one forming a soluble, the other an insoluble compound with lime.

But, more recently, Zeise 5 has submitted tobacco smoke to a careful analysis, and gives the following as its constituents: A peculiar empyreumatic oil, butyric acid, carboxic acid, ammonia, paraffine, empyreumatic resin, water, probably some acetic acid, more or less carbonic oxide, and carburetted hydrogen. To the absence of creosote is, perhaps, to be ascribed the less acrid quality of tobacco smoke than of wood smoke. Meinsen 6 has subsequently directed *nicotina* in tobacco smoke.

The purified empyreumatic oil of tobacco passes over colourless, but soon becomes yellowish, and ultimately brownish. Its sp. gr. is 0.870. It is soluble in alcohol and in ether, but not in water. Its composition is C11H10O4.—In the impure state, Dr. Morres 7 describes the oil as being rather less solid than the empyreumatic oil of foxglove (see p. 457); but it is indistinguishable from the latter by either taste or smell. In this state it probably contains some nicotina. It has been suggested that this oil is "the juice of cursed hebenon," alluded to by Shakespeare, 8 who also calls it a "distillment."

**Characteristics.**—The characteristics of tobacco leaves are partly botanical, partly chemical.

The botanical characters which apply to large and perfect leaves have been before stated (see ante, p. 456); those used to detect small fragments will be noticed under the head of adulterations (see infra).

The following are the chemical characters, as given by Dr. Ure, 9 of a filtered cold infusion of tobacco, prepared by macerating 100 grs. of dried Virginian tobacco in 1000 grs. of distilled water: "Infusion pale brown; acid reaction with litmus paper; nitrate of barytes, 0; nitrate of silver, a faint opalescence, but no curdy precipitate; oxalate of ammonia, a faint cloud of calcareous matter; water of ammonia, 0; chloride of tin, a faint white precipitate—hence no sulphuretted hydrogen present; chloride of platinum, a copious white precipitate, from the ammoniacal salt present; acetate of lead, an abundant whitish precipitate, soluble in nitric acid; chlorides of iron caused a green tint, and sulphate of copper an olive brown, both resulting from the yellow of the iron, and blue of the copper solutions, with the brown of the tobacco."

The mode of determining the percentage quantity of nicotina in tobacco has been already mentioned (see ante, p. 489).

The peculiar odour of tobacco smoke, as well as the remarkable sensation of acridity which both it and tobacco leaf excite in the throat, may sometimes aid in the detection of tobacco. (See, on this subject, *Loebelia inflata.*)

---

4. Poggendorff's Annalen, viii. 399.
8. Supplement to his Dictionary, p. 221.
ADULTERATION.—From the evidence laid before a committee of the House of Commons in 1844, it appears that adulteration of tobacco has been (and probably still is) very general, and has varied from 5 to 40 per cent.; in some cases being carried as far as 100 per cent. of the tobacco.

The substances used for adulterating are numerous and various. Water being necessary, in the manufacture of tobacco, and being allowed by law, can scarcely be called an adulterating ingredient, though it serves to increase the weight of the tobacco. In the preparation of Shag tobacco, about 12 per cent. of water is used in this country. Saccharine matter (sugar, molasses, honey, &c.), which is the principal adulterating ingredient, is said to be used both for sophistication and for rendering the tobacco more agreeable. Vegetable leaves (as of rhubarb and beet), mosses, bran, malt-combs (sprout of the malt), beetroot dregs, liquorice, terra japonica, rosin, salts (nitre, common salt, and sal ammoniac), yellow oche, fuller's earth, and sand, are stated (see the Tobacco Report) to have been employed as adulterating agents.

The detection of adulteration is in some cases easy, in others difficult, if not impossible. Two methods of analysis have been resorted to; one mechanical, the other chemical.

The presence of foreign bodies may sometimes be detected by the naked eye, at other times the use of a magnifying-glass or microscope is necessary to detect them. Tobacco leaves present several remarkable (though not peculiar) characters which lend important aid in detecting adulterations: these are—1st, the horseshoe or crescentic mark seen on a transverse section of the leaf-stalk; 2dly, the glandular character of the hairs; 3dly, the size and shape of the meshes or reticulations of the epidermis; 4thly, the size, shape, and number, in a given space, of stomata.

The chemical characters or tests on which reliance has been placed in detecting adulterations are chiefly the following: 1st, the relative proportions of matters soluble and insoluble in water. The substances insoluble in water are called by the excise officers "lignieous matters," and for Virginia, Missouri, and Kentucky tobacco amount to from 45 to 55 per cent. Porto Rico tobacco, however, yields 70 per cent. of lignieous matters. The matters soluble in water are termed "extractive," and, of course, make up the difference. It is obvious, however, that no reliance can be placed on this test (on account of the great variations in the proportions of the two constituents) unless a portion of the pure leaf, from which the suspected manufactured tobacco was made, can be obtained for comparison. 2dly, genuine tobacco mixed with yeast and water, and submitted to a proper temperature, does not undergo the vinous fermentation; but tobacco which has been adulterated with saccharine matter undergoes this kind of fermentation and yields alcohol (see ante, p. 150). 3dly, Trommer's test is employed to distinguish grape sugar and molasses

On the continent, tobacco is more coarsely cut, and, therefore, less water is required in its manufacture.

Dr. Ure, in his evidence (Quest. 8849), states that he is quite sure that he "could not adulterate tobacco as to evade every chemical and microscopic examination." 1

Mr. Richard Phillips, Professor Graham, and Mr. George Phillips, employed mechanical means chiefly in the analysis of various samples (some adulterated, others unadulterated) of tobacco submitted to their examination by the Parliamentary Committee (Quest. 7511—12).

The horseshoe or crescentic mark seen in the centre of the leaf-stalk of tobacco is the mass of woody fibres and vessels which eventually make the veins of the leaf. This character, though much relied on by the excise officers, is not peculiar to tobacco—being found in strangonium, belladonna, and some other leaves. It is, however, absent in rhubarb leaves.

The hairs of tobacco leaves are tipped by a small spherical or ellipsoid gland. In rhubarb and potato leaves, the hairs are lymphatic, not glandular.

In tobacco, the meshes seen on the epidermis are bounded by sinuous lines.

Dr. Ure (Quest. 8778) declares that the amount of residuum or ligneeous matter is as variable from the genuine tobacco as from adulterated specimens furnished him by the Parliamentary Committee; and he, therefore, declares this test as good for nothing.

Dr. Ure objects to the fermentation test that it might be rendered nugatory by adding to the tobacco substances which are known to prevent fermentation in sugar (see ante, p. 84, footnote 8). Thus it has been long known in Burgundy that a little red precipitate of mercury, when added to must (juice of the grape), prevents fermentation. He also observes (Supplement to his Dictionary, p. 253), that it would seem from experiments made by Professor Graham and Meares, Phillips, that infusions of tobacco without sugar, when mixed with brisk yeast, and placed for forty hours in a temperature of about 90° F., undergoes a certain degree of decomposition, attended with a diminution of their specific gravity; or, in the language of the Excise, they suffer attenuation.
from cane sugar (see ante, p. 150). 3dly, treating the samples with alcohol, and examining the alcoholic solution and the parts insoluble in alcohol. 4thly, incinerating the suspected sample, and determining the amount and nature of the ashes. According to Mr. Johnston, the percentage of ash left by the dry tobacco leaf varies from 19 to 27 per cent. of its whole weight; Pelouze and Prémý, on the other hand, state that for leaves and ribs dried at 212° it varies from 17 to 24 per cent., and for stalks from 6 to 16 per cent. The nature and solubility of the ashes, and the proportion of silica in them, are subject to great variation. 5thly, the determination of the amount of nitrogen; but Dr. Ure, who suggested this line of research, has satisfied himself that this method can serve no good purpose. 6thly, special tests are required for the detection of particular substances suspected to be present. Thus for terra japonica the tests employed are the salts of iron and gelatine, by which the presence of an astringent matter is indicated.

Physiological Effects. a. On Animals generally.—In the carnivora, tobacco causes nausea, vomiting, sometimes purging, universal trembling, staggering, convulsive movements, and stupor. Five draughts and a half of rum introduced into the stomach of a dog, and secured by a ligature on the oesophagus, caused death in nine hours. In another experiment, two draughts applied to a wound killed the animal in an hour. Sir B. Brodie found that the infusion of tobacco, thrown into the rectum, paralyzed the heart, and caused death in a few minutes. But if the head of the animal be previously removed, and artificial respiration kept up, the heart remains unaffected; proving that tobacco disorders this organ through the medium of the nervous system only. In the herbivora, the effects of tobacco, as of other vegetable poisons, are much less marked; vomiting does not occur. Schubart found that the infusion of tobacco, from the leaves to a horse, at three times within two hours. The pulse became irregular, then slower, afterwards quicker; respiration and the pupils were scarcely affected. For two days the stools and urine were more frequent. Moiroud observed no remarkable effect from the exhibition of a decoction of four ounces of tobacco to a horse.

It is remarkable that the empyreumatic oil of tobacco does not possess the same power of paralyzing the heart. Applied to the tongue of a cat, one drop caused convulsions, and in two minutes death; on opening the body, the heart was beating regularly and with force. Its operation, therefore, is analogous to that of hydrocyanic acid. Dr. Morries says it has less tendency to induce convulsions than the empyreumatic oils of foxglove, henbane, or the thornapple.

b. On Man.—In small doses, tobacco causes a sensation of heat in the throat, and sometimes a feeling of warmth at the stomach; these effects, however, are less obvious when the remedy is taken in a liquid form, and largely diluted. By repetition it usually operates as a diuretic, and less frequently as a laxative. Accompanying these effects are oftentimes nausea and a peculiar feeling usually described as giddiness, but which scarcely accords with the ordinary acceptance of this term. As dropical swellings sometimes disappear under the use of these doses, it has been inferred that the remedy promotes the operation of the absorbents. In larger doses, it provokes nausea, vomiting, and purging. Though it seldom gives rise to abdominal pain, it produces a most distressing sensation of sinking at the pit of the stomach. It occasionally acts as an anodyne, or more rarely promotes sleep. But its most remarkable effects are languor, feebleness, relaxation of muscles, trembling of the limbs, great anxiety, and tendency to faint. Vision is frequently enfeebled, the ideas confused, the pulse small and weak, the respiration somewhat laborious, the surface cold and clammy, or bathed in a cold sweat, and, in extreme cases,

1 Lectures on Agricultural Chemistry, p. 391, 1847.
2 Cours de Chimie Générale, t. iii. p. 233, 1850.
4 Tobacco Report, p. 460; and Supplement to his Dictionary, p. 230, 1844.
5 Ortlín, Zig. Gésam.
8 Brodie, op. cit.
convulsive movements are observed. *In excessive doses,* the effects are of the same kind, but more violent in degree. The more prominent symptoms are nausea, vomiting, and in some cases purging, extreme weakness and relaxation of the muscles, depression of the vascular system (manifested by feeble pulse, pale face, cold sweats, and tendency to faint), convulsive movements, followed by paralysis and a kind of torpor, terminating in death.

Taken in the form of *snuff,* its principal effect is topical. It causes increased secretion of nasal mucus, and, in those unaccustomed to its use, sneezing. **Getting into the throat it produces a feeling of acridity, and sometimes nausea. From some kinds of *rappee* I have experienced giddiness and great prostration of strength. Lanzoni states that an individual fell into a state of somnolency, and died lethargic on the twelfth day, in consequence of taking too much snuff. *Reasonable doubt, however, may be entertained, I think, whether these accidents really arose from snuff. The habitual use of this substance blunts the sense of smell and alters the tone of voice; but I am unacquainted with any other well-ascertained effects, though Cullen ascribes loss of appetite and dyspepsia to it; and Dr. Prout observes, that "the severe and peculiar dyspeptic symptoms sometimes produced by inverteate snuff-taking are well known; and I have more than once seen such cases terminate fatally with malignant diseases of the stomach and liver." *I have known several inverteate snuff-takers who, after many years' use of this substance, have discontinued it with impunity; but Dr. Cullen thinks, that when the discharge of mucus is considerable, the easing or suppression of it, by abstaining from snuff, is ready to occasion the very disorders of headache, toothache, and ophthalmia, which it had formerly relieved. There do not appear to be any good grounds for the supposed baneful effects of the manufacture of snuff on the workmen.* Sir W. Temple recommends the introduction of a tobacco leaf into the nostrils for the relief of affections of the eyes and head.

The **smoking** of tobacco by those unaccustomed to it, gives rise to all the before-described effects of large and excessive doses. *A very interesting case, which had almost terminated fatally, is related by Dr. Marshall Hall.* It was that of a young man, who, for his first essay, smoked two pipes. Gmelin mentions two cases of death from smoking, in the one of seventeen, in the other of eighteen pipes at a sitting.

In habitual smokers, the practice, when employed moderately, provokes thirst, increases the secretion of saliva and buccal mucus, and produces a remarkable soothing and tranquilizing effect on the mind, which has made it so much admired and adopted by all classes of society, and by all nations civilized and barbarous. *I am not acquainted with any well-ascertained ill effects resulting from the habitual practice of smoking.* A similar observation is made by Dr. Christison. Yet Dr. Prout says it "disorders the assimilating functions in general, but particularly, as I believe, the assimilation of the saccharine principle. *I have never, indeed, been able to trace the development of oxalic acid to the use of tobacco; but that some analogous and equally poisonous principle (probably of an acid nature) is generated in certain individuals by its abuse, is evident from their cachectic looks, and from the dark, and often greenish-yellow tint of their blood." *There do not appear to be any good grounds for supposing that smoking is a prophylactic against contagious and epidemic diseases—an opinion at one time entertained. The practice of chewing tobacco is principally confined to sailors, and is less frequently submitted to our observation; so that we are not so competent to speak of its effects, which, probably, are similar to those caused by smoking.

The application of tobacco to abraded surfaces is a very dangerous practice, and has in some instances been attended with violent or even fatal results. Mr. Wes-

---

8. (Quoted by Christison.)
ton has related a case in which the expressed juice of tobacco was applied to the head of a boy, aged eight years, for the cure of tinea capitis. Death took place three hours and a half after the application.

In the form of clyster, tobacco has frequently proved fatal, sometimes from the use of inordinate doses by ignorant persons, and occasionally in the hands of the well-informed practitioner. Desault has witnessed the smoke prove fatal. Sir A. Cooper has seen two drachms, and even one drachm, destroy life. In a case related by Sir Charles Bell death probably occurred from the same cause. Dr. Copland saw half a drachm in infusion prove fatal.

The operation of tobacco resembles that of Lobelia inflata (see Lobeliaceæ). With foxglove, tobacco agrees in several circumstances, especially in that of enfeebling the action of the vascular system, though its power in this respect is inferior to that of foxglove. In its capability of causing relaxation and depression of the muscular system, and trembling; tobacco surpasses foxglove; as it does, also, in its power of promoting the secretions. From belladonna, stramonium, and hyoscyamus, it is distinguished by causing contraction of the pupil, both when applied to the eye and when taken internally in poisonous doses; and also by the absence of delirium and of any affection of the parts about the throat. Vogt and Sundelin have considered the effects of tobacco as closely allied to those of aconite; but to me the resemblance is less obvious (see Ranunculaceæ). The power possessed by the last-mentioned substance of paralyzing the sentient nerves sufficiently distinguishes it from tobacco.

Uses.—The principal remedial value of tobacco consists in its power of relaxing muscular fibres, whereby it becomes a valuable antispasmodic. As a purgative, but especially as an antispasmodic and purgative conjoined, it is exceedingly serviceable in alvine obstructions. As a sedative to the vascular system it has not been much used. I tried it somewhat extensively a few years since, as a substitute for bloodletting, in inflammatory affections; but, while it produced such distressing nausea and depression that it was with difficulty I could induce patients to persevere in its use, I did not find its antiphlogistic powers at all proportionate, and eventually I discontinued its employment. As an anodyne, diuretic, or emetic, it is much inferior to many other articles of the Materia Medica.

1. In colic, ileus (volvulus), strangulated hernia, and constipation.—The efficacy of tobacco in these diseases depends principally on its power of relaxing muscular fibres and on its purgative properties. These effects are usually accompanied by nausea and giddiness. The remedy is applied in the form of clyster, consisting either of the infusion or of the smoke. The latter was at one time supposed to be more efficacious. Heberden says it causes less giddiness than the infusion. It probably extends farther up the intestines than the liquid enema, and, therefore, acts on a larger surface. But the difficulties and inconvenience of applying it, and the uncertainty of its effects, have led, for the most part, to the discontinuance of its use. In ileus, the tobacco clyster has been recommended by Sydenham, by Heberden, by Abercrombie, and by several other distinguished authorities. The earlier it is resorted to, the more successful is it likely to prove. Indeed, when employed in the last stage of the disease, it sometimes hastens the fatal termination by exhausting the already depressed vital powers. As it is occasionally necessary to repeat the injection, it is of importance to begin cautiously. Dr. Abercrombie uses only fifteen grains of tobacco infused in six ounces of boiling water for ten minutes, and he repeats this in an hour if no effect have been produced. I have generally employed a scruple, and have not experienced any dangerous effects from

its application; and it is possible that, in persons long accustomed to the use of tobacco, a somewhat larger dose might be required; but I have never met with any cases in which a seruple did not produce the full effect on the system that was desired. In strangulated hernia, the tobacco clyster has frequently effected the return of the protruded parts when the operation appeared almost inevitable; and every surgical writer speaks in the highest terms of its use. A tense hernial tumour sometimes becomes soft and relaxed by the diminished force of circulation produced by tobacco. Notwithstanding these facts, this remedy is much less resorted to than formerly. Three circumstances have, I suspect, led to the infrequency of its use—first, the dangerous, if not fatal, consequences which have sometimes resulted from its employment; secondly, the frequency of its failure, and the consequent loss of time, by which the chance of recovery is diminished; thirdly, the operation for hernia being much less dreaded now than formerly, for experience has fully proved that death rarely (Mr. Pott says only once in fifty times) results from it. In colic from lead, and in obstinate constipation from spasmodic constipation, the tobacco clyster has sometimes proved most beneficial. Of the application, in lead colic, of compresses soaked in a strong decoction of tobacco, to the abdomen, as recommended by Dr. Graves, I have no experience. The practice is, of course, calculated to be beneficial, but is less certain and speedy in its effect than tobacco clysters.

2. 

In ischuria and dysuria.—When retention of urine arises from spasm of the neck of the bladder, or from spasmodic stricture, tobacco, by its powerfully relaxing properties, is an agent well calculated to give relief. Mr. Earle has published several cases illustrative of its efficacy. In dysury, also, tobacco proves serviceable; it abates pain, relaxes the urinary passages, promotes the secretion of urine, and, by diminishing the sensibility of the parts, facilitates the expulsion of calculous matter.

3. 

Tetanus.—The relaxing influence over the muscular system possessed by tobacco, suggested the employment of this remedy in tetanus. Its effects have been, like those of most other medicines in this disease, unequal. Sir J. Macgregor says, that in the advanced stage of the malady the tobacco clyster had no effect. Mr. Earle, however, thought it afforded temporary alleviation in a case in which he tried it. Since then, several cases have been successfully treated by tobacco. Dr. O’Beirne obtained most marked relief by its use. He employed it in the form of clyster (containing a seruple of tobacco), which was repeated once or thrice or oftener daily during eighteen days; and it was observed that if by design or accident the remedy was discontinued, the spasms recurred with force. Mr. Anderson employed a decoction of the fresh leaves in the form of enema, and both with good effect. Mr. Curling has collected accounts of nineteen cases (including those of Earle, O’Beirne, and Anderson, above referred to) treated by tobacco; of these, nine recovered; and in seven of the fatal cases the remedy had not a fair trial; while in the eight, organic disease of the brain was found. Mr. Curling observes, that "more has now been advanced in proof of the efficacy of tobacco than can be adduced in favour of any other remedy yet resorted to. I have not," he adds, "succeeded in finding a single case in which, being fully and fairly tried before the constitution had given way, it has been known to fail."

4. 

Other spasmodic diseases.—The success attending the use of tobacco in tetanus has led to its employment in hydrophobia, but hitherto without avail. In a case of periodic epilepsy, Dr. Currie prevented the return of the disease by the application of a tobacco cataplasm to the serobiculus cordis half an hour before the expected paroxysm. In a very bad case of spasm of the rima glottidis, which resisted powerful depletion by the lancet, Dr. Wood applied with success a tobacco
VEGETABLES.—NAT. ORD. SOLANACEÆ.

cataplasm to the throat. In *spasmodic asthma*, tobacco, either smoked or taken internally, in nauseating doses, has been found occasionally to give relief. My own observation is unfavourable to the use of tobacco smoke, which I have repeatedly found to bring on convulsive cough and spasmodic difficulty of breathing in persons afflicted with chronic catarrh. Dr. Sigmond¹ says the tincture of tobacco has been sold and used to a great extent under the name of tincture of lobelia, and that it proved successful in spasmodic asthma. In *rigidity of the os uteri*, a tobacco enema failed to produce relaxation, while it caused alarming constitutional symptoms.²

5. In *dropsy*.—Tobacco was recommended as a diuretic in dropsy by Dr. Fowler,³ who published a number of cases of anasarca and ascites which had been relieved by it.⁴ Whatever benefit may have been obtained in these cases, by the use of tobacco, should be ascribed, I suspect, rather to the sedative powers of this agent than to its influence over the kidneys. In small doses it is an uncertain diuretic, and in larger doses it causes such distressing nausea and depression that practitioners have long since ceased to use it in dropisical cases. The ashes of the tobacco plant have also been used in dropsy.⁵

6. As a *topical remedy*.—Dr. Vetch⁶ recommends the infusion, as an anodyne and sedative topical application, in gouty and rheumatic inflammation of the joints, testicle, and sclerotic coat of the eye, and in erysipelas inflammation. Bergius⁷ recommends a fomentation of tobacco leaves in phymosis and paraphymosis. An infusion or ointment of tobacco has been used in porrigo and other skin diseases, as well as in some obstinate ulcers. The smoke, applied to the hair, is a popular means of destroying pediculi, and has been used, in the form of enema, to destroy ascarides. Dr. Sigmond⁸ says tobacco promotes the growth of the hair. Tooth-ache has been relieved by tobacco smoke.

In addition to the preceding, there are various other diseases against which tobacco has been employed. Thus in *soporose affections* and *asphyxia*, tobacco enemata and enemas have been employed, but they are more likely to do harm than good. Tobacco has also been used as an antihelminthic.

**Administration.**—Tobacco is rarely administered in substance. Five or six grains of snuff have been taken as an emetic, and are said to have operated as effectually as two grains of emetic tartar. For internal administration the wine of tobacco is generally employed. Dr. Fowler used an infusion (prepared with an ounce of Virginian tobacco to a pound of boiling water), which he gave in doses of from sixty to a hundred drops. The best time for administering it he found to be two hours before dinner, and at bedtime. The usual *tobacco enema* is the infusion prepared according to the Pharmacopœia. The tobacco smoke enema (enema *fumo tabaci*) is applied by means of a proper apparatus, formerly kept by the instrument-makers. Various extemporaneous methods of employing it have been devised.⁹ For external use tobacco is used in the form of cataplasm (made of the leaves and water and vinegar), infusion (the tobacco water of the shops), smoke, and ointment: all these, however, require great caution in their use, especially when applied to abraded surfaces.

**Antidotes.**—If the poison have been swallowed, let the contents of the stomach be withdrawn as speedily as possible. No chemical antidote has as yet been demonstrated; but the vegetable astringents (infusion of nutgalls, green tea, &c.) deserve examination. As anti-narcotics, the vegetable acids and coffee may be administered. The other parts of the treatment must be adapted to circumstances. When the depression of the vascular system is extreme, ammonia and brandy may be administered with good effect, and frictions employed; even acupuncture of the heart (!) has been suggested.¹⁰ Artificial respiration should not be omitted when other means

have failed. If apoplectic symptoms present themselves, bloodletting may, perhaps, be requisite, as in the case related by Dr. M. Hall.

1. ENEMA TABACI, L. E. D.; Infusum Tabaci [U. S.]; Tobacco Clyster.—(Tobacco 3j [grs. xv to 3ss, E.]; Boiling Water Oss [3vij, E. D.]. Macerate for an hour [half an hour, E.], and strain.)—The want of uniformity in the formula of the British Colleges is greatly to be regretted; and I cannot but think that the latitude permitted by the Edinburgh College, in the quantity of tobacco employed, is highly objectionable, and calculated to lead to serious errors in dispensing. The tobacco clyster is used, as I have already stated, in ileus (volvulus), strangulated hernia, obstinate constipation, retention of urine, &c. It is not to be forgotten that two drachms, one drachm, and even half a drachm of tobacco infused in water, have proved fatal, as I have before mentioned. The cautious practitioner, therefore, will not use more than 15 or 20 grains.

[The U. S. Pharm. directs Tobacco 3j; Boiling Water Oj. Macerate for an hour in a covered vessel, and strain. This is intended to be used cautiously, only portions being administered at a time, in accordance with the above statements.]

2. VINUM TABACI, E. [U. S.]; Wine of Tobacco.—(Tobacco 3ijss; Sherry Oij. Digest for seven days, strain, express strongly the residuum, and filter the liquors.) [The U. S. Pharm. directs Tobacco 3j; Wine Oj. Digest for fourteen days and filter.—Sedative and diuretic. Employed in dropsy, dysury, &c. Rarely used. Dose from m.x to m.1.]

3. ENGENTUM TABACI, Ph. United States; Ointment of Tobacco.—(Fresh Tobacco, cut in pieces, 3j; Lard lbj. Boil the tobacco in the lard, over a gentle fire, until it becomes friable; then strain through linen.)—Employed as an application to irritable ulcers and skin diseases, especially tinea capitis; but its use requires great caution.

An ointment, prepared with twenty drops of the empyreumatic oil of tobacco and an ounce of simple ointment, has been applied with advantage, by American practitioners, to indolent tumours and ulcers; but like all other preparations of tobacco, when employed externally, must be used with great caution.1

175. SOLANUM TUBEROSUM, Linn.—COMMON POTATO.

Sex. Syst. Pentandria, Monogynia.
(Herba; Tuber.)

History.—Pedro de Cieca, in his Chronica del Peru, published at Seville, in 1553, is the first writer who mentions potatoes. They probably first came into Europe from the neighbourhood of Quito to Spain. In 1586, they were brought to England from Virginia by the colonists sent out by Sir Walter Raleigh, in 1584.

Botany. Gen. Char.—Calyx 5—10-cleft. Corolla hypogynous, rotate or rarely campanulate; tube short; limb plaited, 5—10., rarely 4—6-cleft. Stamens 5, rarely 4 or 6, inserted in the throat of the corolla, exserted; filaments very short; anthers equal or sometimes unequal, converging, dehiscent by two pores at the apex. Ovary 2., rarely 3—4-celled; the placenta attached to the dissepiments, adnate, with numerous ovules. Style simple; stigma obtuse. Berry 2., rarely 3—4-celled. Seeds numerous, subreniform. Embryo peripheral, spiral, inclosing fleshy albumen (Endlichier).

Hab.—West coast of South America. Cultivated everywhere.

The cultivated varieties of the potato are very numerous. They are distinguished according to their precocity, lateness, form, size, colour, and quality.

Description.—1. The part of the plant which is used as food, is the tuber

1 United States Dispensatory.
(tuber solani tuberosi) attached to the subterranean stem, of which, in fact, it may be regarded as a part in a state of excessive development. It is provided with a number of buds, commonly called eyes, which, with contiguous portions of the potatoes, are used, under the name of sets, for multiplying the species. The tubers vary in shape; being round, oblong, or kidney-shaped. When boiled, they vary in quality; being watery, waxy, or mealy. When examined by the microscope, the tissue of the potato is found to consist of a mass of cells, between and within which is an albuminous juice. Each cell also contains about ten or twelve starch grains (Fig. 308, a). By boiling, the cells are separated, the starch grains absorb the albuminous liquid, swell up, and completely fill the cells; while the albumen coagulates and forms irregular fibres, which are placed between the starch grains (Fig. 308, b). Potatoes in which these changes are complete are called mealy, while those in which the liquid is only partially absorbed, and the coagulation imperfectly effected, are denominated doughy or watery. By boiling in water, potatoes do not form a jelly or mucilage like mere starch, because the starch grains in the tubers are protected partly by the coats of the cells in which they are contained, and partly by a layer of coagulated albumen.

2. For medicinal purposes the herb (herba solani tuberosi), including both stems and leaves, has been employed.

**Composition.**—Potatoes have been repeatedly subjected to chemical examination. The following are the results of analyses made by Michaelis and by Johnston.

Red variety of potato 100.000 100.00 . 100.00

As a portion of both albumen and gluten adheres to the fibre, and of both, with some of the casein, to the starch, the true percentage of protein matters is what understated in the above table; and Johnston, therefore, gives the following as the representation, in round numbers, of the composition of the dry potato: starch 61, sugar and gum 15, protein compounds 9, fat 1, and fibre 11.

The proportion of water, starch, and protein matters in the potato, according to the investigations of Horsford and Krocker, have been already given (see vol. i. p. 119.)

The ultimate composition of the potato, according to Boussingault, is as follows:—

3. Archiv d. Pharm. xii. 233; and Pharm. Central-Blatt für 1838.

* Ann. de Chimie et Physique.
Baup, Spatzier, and Otto have found solanina in potatoes.

1. Solanina; Solanine; Potato-Solanin.—Found chiefly in the buds and shoots (sprouts) of the potato; also in the leaves, stalks, and fruits. Even sound ripe potatoes (the tubers) contain traces of it; but diseased potatoes, according to Liebig, do not yield it. (For the properties of Solanina, see Solanum Dulcamara.)

2. Starch (see p. 501).

3. Protein Compounds; Albumen, Glutin, and Casein.—The juice of the potato coagulates when heated, owing to the albumen which it contains. If the washings of a grated potato be heated to coagulate the albumen, and a little acetic acid be added to the strained liquor when cold, a white powder, called casein, is precipitated. If dry potato in powder be boiled in alcohol, the solution evaporated, and water added to it, a substance resembling the gluten of wheat is obtained. In potatoes which have been kept for some time, the proportion of protein matters is diminished.—In diseased potatoes, the protein compounds appear to be the constituents chiefiy affected: the albumen is diminished in quantity, and altered in quality, becoming dark, especially on coagulating; while, according to Liebig, the casein is augmented in quantity.

4. Fat.—Either extracts from dried sliced potatoes a minute portion of fatty matter.

5. Gum (Dextrine) and Sugar.—Healthy potatoes contain small portions of that variety of gum called dextrine, and also of sugar. When the quantity of these ingredients is unusually large, as in diseased potatoes, the quantity of starch is proportionately small.

6. Cellulose; Fiber; Lignin.—The proportion of this constituent of the potato is subject to great variation. As usually obtained, it contains some adherent starch and protein matters: hence the nutritive qualities of the pulp of potato mills, which is used for feeding cattle.

7. Acids and Salts.—The vegetable acid which exists in potatoes, and which several chemists have declared to be citric acid, is, according to Lisch, malic acid. He also detected phosphoric and hydrochloric acids. By the microscope, crystals of oxalate of lime can be detected. The quantity of ash obtained by drying and burning the potato, varies from 0.76 to 1.58 of the weight of the potato in the natural state. It consists, in large proportion, of potash salts, with some soda and lime salts. These bases are combined with carbonic acid (produced by the decomposition of the malic and oxallic acids), phosphoric acid, sulphuric acid (formed by the oxidation of the sulphur of the protein matters), and hydrochloric acid.

Diseases of the Potato.—The potato is subject to various diseases, the chief of which are the curl, the scab, and two sorts of rot—one called the dry rot, the other the wet rot. Martius mentions two other maladies also; namely, the rust, and the blue pock, but they are imperfectly known. The disease, called the potato-murrain, or potato blight, which recently raged epidemically among the potatoes of Europe and America, was a kind of rot, usually of the humid or wet kind. The cause of this, as of the other maladies of the potato, is very obscure.

The scab (porriga tuberum solani) is characterized by the surfaces of the tubers becoming "covered with pustules, which at length become cup-shaped, and are powdered within with an olive-yellow meal, consisting of the spores of a fungus," which Martius calls Protomyces Tuberum Solani, but which Mr. Berkeley terms Tubercinia Scabies (Sub-order Hypomyces—see ante, p. 80).

In the dry rot (gangrena nica tuberum solani) the tubers, when stored for winter use, or when planted, become impregnated with a kind of mould, and are at length so hard that they can scarcely be broken, and, instead of producing shoots, merely throw out a few small misshapen tubers. In 1830, this disease was first noticed in Germany. Martius ascribes it to the growth of a peculiar fungus, the Fistariosum Solani (Sub-order Hypomyces—see ante, p. 80).

The wet rot (gangrena humida tuberum solani) differs from the preceding in the circumstance that the tubers become soft instead of hard; and parasitic fungi, referred by Fries to his genus

1 Ann. de Chimie, 1826.
4 Baup (Buchner's Repert. Ste Rehbe, Bd. iii. p. 360, 1838) says that the potato yields sufficient citric acid to admit of its being employed for the preparation of this acid for commercial purposes. He also states that he found succinic acid and a new acid, which he calls solana-tuberic acid, in potatoes.
7 Die Kariafel-Epidemie der letzten Jahren oder die Stockguite und Route der Kastanien, geschildert und in ihren wissenschaftlichen Verhaltnissen erortert, von Dr. C. Fr. Ph. v. Martius, Munchen, 1842.
8 The first notice of the disease in England was by Dr Bell Salter, in the Gardener's Chronicle, Aug. 16, 1845.
9 The fungal hypothesis of the potato blight has been ably advocated by Mr. Berkeley, in a paper entitled Observations, Botanical and Physiological, on the Potato Murrain, published in the Journal of the Horticultural Society, vol. i. p. 2, 1846. Most authors ascribe the disease to peculiar atmospheric or meteorological conditions. Mr. Sims (The Potato Plant, its Uses and Properties, together with the Cause of the Present Malady, 1846) attributes it to an animal parasite, the Aphis caviator—a species of hemipterous insect, which punctures the leaf, sucks the sap, and, by exhausting the plant, causes the death of the leaf or of some other part.
VEGETABLES.—NAT. ORD. SOLANACEAE.

**Periola** (Sub-order Gasteromycetes—see **ante**, p. 88), appear, for the most part, under the form of hemispherical masses bursting through the cuticle.

The *potato murrain*, or *potato blight*, commonly called the *potato disease*, is closely allied to, if it be not identical with, the rot—usually, the wet rot. But, according to Mr. Berkeley, it is characterized by the presence of *Botrytis infestans* (Sub-order Hyphomycetes—see **ante**, p. 80). The malady commences in the leaves, and extends from thence by the stems to the tubers. Both on the inferior surface of the leaves and in the tubers a peculiar fungus has been discovered, called by Dr. Montagne the *Botrytis infestans*, which has been very fully described and figured by Mr. Berkeley.—The malady seems to affect chiefly the protein constituents of the potato. Liebig states that a part of the vegetable albumen which usually prevails in the potato has become converted into casein. The starch appears to be unaltered in quality.

**Physiological Effects.** 1. Of the herb.—An extract obtained from the stalks and leaves of potatoes was declared by Dr. J. Latham to possess narcotic properties in doses of two or three grains, but the cases adduced are not satisfactory. Furthermore, his experiments were repeated by Dr. Worsham with very different results, for 100 grains produced no sensible effects. The observations of Nauche, however, tend to confirm Latham's statements.

2. Of the tubers.—Potatoes, when in good condition, and cooked by boiling, form a nutritious and easily digestible article of food. The starch, sugar, gum (dextrine), and fat, serve for the production of fatty matters, sugar, lactic acid, and, by combustion, of heat and carbonic acid. The protein matters (albumen, gluten, and casein) are plastic elements of nutrition, and serve for the production of fibrous, albuminous, and gelatigenous tissues. According to Gunsford, the non-digestible constituents of the potato, and which he found in the excrements, are the cellular, fibrous, and vascular tissues, with which some undigested starch grains are intermixed.

Potatoes are valuable antiscorbutics. Sir G. Blane, Julia Fontanelle, Nauche, Dr. Baly, and others, have testified to their valuable preservative qualities against scurvy. These have been ascribed to the vegetable acids contained in the tubers, but Dr. Garrod (see vol. i. p. 461) attributes them to the presence of a large quantity of potash.

From an experiment made at the Glasgow Bridewell, it would appear that baked potatoes are less nourishing than boiled ones.

The process of cooking potatoes is useful in two ways; by effecting changes in the nutritive principles (e. g. rendering the starch digestible), and by extracting some noxious matter (solanina). The water in which potatoes are boiled possesses some noxious properties; Nauche found that it augmented the renal and biliary secretions, and slightly affected the nervous system.

Uses. 1. Of the herb.—The extract has been used as a narcotic and antispasmodyc to allay cough, spasm, rheumatic pains, &c. The dose is from one-eighth to half a grain.

2. Of the tubers.—Scraped potato is a popular application to burns and scalds. Boiled potatoes have been used for the formation of emollient poultices. They may be employed as an antidote in poisoning by iodine (see vol. i. pp. 292 and 405). For dietetical purposes potatoes are valuable antiscorbutics. In diabetes, however, they are objectionable on account of the large quantity of starch which they contain. But bread made of potato and cellulose (rasped potatoes deprived, by washing, of starch) has been employed as a *bread for diabetic patients*. Potatoes are used by bakers in the preparation of the ordinary loaf bread of London (see **ante**, p. 126).

---

5. *Percy, Chemical Gazette*, vol. vii. p. 119, 1849.—The following is Mr. Palmer's receipt for making this bread: "Take the ligneous matter of 16 lbs. of potatoes washed free from starch, ½ lb. of mutton suet, ½ lb. of butter, 12 eggs, ½ oz. of carbonate of soda, and 2 oz. of dilute hydrochloric acid. This quantity to be divided into eight cakes, and in a quick oven baked until nicely browned." Care must be taken to procure pure hydrochloric acid, as some commercial sorts contain arsenic (see vol. i. p. 390).—This bread may be regarded as a substitute for the *bran bread* already described (see **ante**, p. 127).
I. AMYLUM SOLANI TUBEROSI; Potato Starch.—Obtained by washing potatoes, then rasping or grinding them to a pulp, and repeatedly washing the latter with water. The washings are strained through a sieve to separate the fibre or cellular tissue, and then allowed to stand at rest, by which the starch is deposited, and is afterwards washed and dried.

The quantity of starch yielded by potatoes varies with the variety or sort, the soil, the climate, and the season. Payen found the same variety of potato to yield, in October, 17.2 per cent. of starch; in November, 16.8; in December, 15.6; in January, 15.5; in February, 15.2; in March, 15.0; and in April, 14.5. In general, the centre of the potato yields the smallest portion, the heel end which is attached to the rootlet the most, and the rose or upper end an intermediate portion of starch.

Potato starch is white and pulvcrulent, and, on account of the large size of its particles, has a satiny or glistening character. The smaller grains are circular or globular; the larger ones elliptical, oblong, ovate, or obusely triangular. Frequently, their shape is irregular, and approximates to that of an oyster-shell, or a musselshell. Their nucleus, central cavity, or hilum, is very distinct; and their laminated structure is indicated by a system of concentric or excentric rings or zones surrounding the nucleus. It is most allied in appearance to the starches of Marantaeeae. The characters by which they are distinguished from West Indian arrowroot, and from tous-le mois, have been before pointed out (see ante, pp. 226 and 228). The mode of distinguishing potato starch from wheat starch has likewise been stated (see ante, p. 125).

In its general chemical properties it agrees with other starchy bodies. In cold water it is insoluble. If 1 part of potato starch be mixed with 15 parts of water, and heated, the liquid begins to be thick and mucilaginous at about 140° F.; and as the heat augments, especially from 162° F. to 212° F., it acquires a pasty or gelatinous consistence. Starch-paste or starch-mucilage is not, however, a true solution of starch in water; the starch grains are burst and exfoliated, the coats or laminae being hydrated and enormously swollen. In cold water, to which a small quantity of caustic potash or soda has been added, they become enormously swollen (see ante, p. 125). Starch-mucilage in the cold becomes intensely blue on the addition of iodine; the colour is destroyed by heat or caustic alkalis.

The greater facility with which potato starch gelatinizes when rubbed in a mortar with a mixture of equal parts of commercial hydrochloric acid and water; the strong smell of formic acid emitted when it is rubbed with hydrochloric acid; the dove-gray colour which it assumes when exposed to the vapour of iodine; and the transparency of the mucilage which it forms with boiling water (whence it has been termed soluble starch), are characters by which it has been attempted to distinguish potato starch from other sorts of starch, but with no great success, as they are not to be relied on.

Potato starch, in the pure or anhydrous state, consists of C₆H₁₀O₆; but, as found in commerce, it contains water.

**Composition of Potato Starch.**

- Anhydrous starch (as combined with oxide of lead)...
- Starch dried in a vacuum at from 102° to 120° F. ...
- Starch dried in a vacuum at 100° F. ...
- Starch air-dried at 95° F. (hygr. 0 0) ...
- Starch dried in air saturated with humidity ...
- Starch drained as much as possible ...

1 The following measurements, in parts of an English inch, of ten particles of potato starch, were made for me by Mr. George Jackson—

Potato starch is sometimes adulterated. M. Dietrich\(^1\) mentions having received some which was adulterated to the extent of 50 per cent. with comminuted fibre, and which prevented the employment of the starch in the fabrication of yeast for a distillery.

Potato starch possesses the alimentary properties of other starchy substances, and which have been before noticed (see vol. i. p. 119, and ante, 107). It does not, however, yield so firm a jelly as some other starches, and has been said to be apt to occasion acidity, especially in infants. It is sold under the various names of potato flour, English arrowroot, Bright’s nutritious farina, &c.; and is used as a farinaceous food for infants and invalids, as well as for the preparation of puddings and soufflés, and, as a thickening ingredient, in gravies, sauces, &c.

Potato starch is used in the production of a factitious sago (see ante, p. 166), in the preparation of dextrine, and in the manufacture of potato sugar (see ante, p. 151).

2. DEXTRINA; Dextrine; Dextrinum; Starch-Gum. Formula C\(^6\)H\(^9\)O\(_6\);HO.

This substance is called “dextrine,” from its property of rotating to the right a ray of plane polarized light. There are three modes of procuring it from starch; viz., by torrefaction, by the action of dilute acids (usually nitric acid), and by the action of diastase. The impure dextrine obtained by torrefying or roasting starch is termed roasted starch or leicomme (from \(\alpha\)ios, smooth; and gome, the French name for gum!). This sort of dextrine resembles British gum (see ante, p. 125), is pulverulent, and has the aspect of starch, but it usually possesses a yellowish tint in consequence of being over-roasted. A second method consists in moistening 1000 parts of potato starch with 300 parts of water, to which 2 parts of nitric acid have been added. The mixture is to be allowed to dry spontaneously, and is afterwards heated, for one or two hours, in a stove at 212\(^\circ\) F. or 250\(^\circ\) F.; the transformation is then complete.

Dextrine is soluble in water and in dilute spirit, but is insoluble in alcohol. Its solution is perfectly limpid; and, by concentration and solidification, it is obtained in an amorphous form like gum arabic. It is sometimes made up in tear-like masses in imitation of gum arabic, and in this state is called artificial gum. This, when fresh, has an odour like that of a cucumber; but, by keeping, I find that it loses this smell. The solution of dextrine yields, with acetate of lead, a precipitate (dextrinate of lead). As usually found in the shops, the solution strikes a violet or reddish tint with iodine; but in this case the starch has been incompletely converted into dextrine, which, when pure, is not coloured by iodine.

Dextrine in many of its characters resembles ordinary gum; from which, however, it is distinguished by its right-handed rotation of a ray of plane polarized light, and by its yielding oxalic acid, but not mucic acid, when heated with nitric acid. Saccharine matter, when mixed with dextrine, may be separated by strong spirit, which more readily dissolves sugar than dextrine. The freedom of dextrine from starch is readly shown by the iodine test.

Dextrine is used in the arts as a substitute for gum, size, and paste. The saccharine solution of dextrine obtained by the action of diastase (contained in the infusion of malt) on potato starch is used in Paris in the manufacture of pains de luxe, and for the fabrication of beer and other alcoholic liquors. In medicine, dextrine is employed as a nutrient, as an emollient, and as an agglutinant. In the French hospitals it is used in tisanes as a substitute for gum. Devergie has employed it with benefit in the treatment of eczema. Velpeau has employed dextrine as a substitute for gum arabic or starch, in the preparation of bandages for maintaining the reduction of fractures by what is called “the immovable apparatus.” For this purpose, 100 parts of dextrine are moistened first with a small quantity of

---

\(^1\) Chemical Gazette, vol. ii. p. 20, 1844.
spirit of camphor, and then mixed with 40 parts of water. The bandages are soaked in the thick mucilage thus obtained.

176. SOLANUM DULCAMARA, Linn. - WOODY NIGHT-SHADE; BITTERSWEET.

**History.** — Fraas declares this plant to be the σκυράκχος ευφόριος of Dioscorides (lib. iv. cap. 73). Sprengel considers it to be the Citocatia of the Abbess Hildegard, of Bingen, who died A. D. 1180. But the derivation of the word Citocatia (cito and cacare) negatives, in my opinion, this supposition. The first undoubted notice of Dulcamara occurs in the work of Tragus.

**Botany.** Gen. Char. — See ante, p. 497.

Sp. Char. — Stem shrubby, zigzag. Leaves cordate-ovate; upper ones auriculate-hastate. Flowers drooping (Babington). Root woody. Stem twining, branched, rising (when supported) to the height of many feet. Leaves acute, generally smooth; the lower ones ovate or heart-shaped; upper, more or less perfectly halbert-shaped; all entire at the margin. Clusters either opposite to the leaves or terminal, drooping, spreading, smooth, alternately subdivided. Bracts minute. Flowers elegant, purple, with two round green spots at the base of each segment. Berries oval, scarlet, juicy.

Hab. — Indigenous. In hedges and thickets, especially in watery situations. Flowers in June and July.

Var. β tomentosum, Koch. — Stem round, almost glabrous throughout. — Woods and hedges; common.

Var. γ marimum, Babington; S. lignosum seu Dulcamara marina, Ray. — Branches of the present year, and leaves flushy and usually clothed with hairs incurved upwards. Stem angular, pros- trate, diffuse, much branched. Leaves all (?) cordate, not hastate. — Pebbly sea-beach. Ren- ville, Cunnamar, Galway; Lizard Point, Cornwall; Shoreham, Sussex (glabrous).

Description. —The annual stems (caules seu stipites dulcamare) are collected in the autumn, after the leaves have fallen.

It is to be gathered in autumn when destitute of leaves. — Ph. Lond.

When fresh, they have an unpleasant odour, which they lose by drying. Their taste is at first bitter, afterwards slightly acrid and sweet. The epidermis is greenish-gray, the wood light, and the pith very light and spongy.

Composition. — The stems have been analyzed by Pfaff. 100 parts of the air-dried stems lost 17.4 parts of water when completely dried. From 100 parts of perfectly dried stems Pfaff obtained bittersweet extractive (picroglycion) 21.817, vege-to-animal matter 3.125, gummy extractive 12.029, gluten with green wax 1.4, resin containing benzoic acid 2.74, gummy extractive, starch, sulphate and vegetable salts of lime 2.0, oxalate and phosphate of lime with extractive 4.0, and woody fibre 62.0 (excess 9.111). Desfosses discovered solanina in the stems.

1. Dulcmarin; Picroglycion, Pfaff; Dulcarin, Desfosse. — Crystaline; has both a bitter and a sweet taste, is fusible, soluble in water, alcohol, and acetic ether, and is not precipitated from its solution by either infusion of nutgalls or metallic salts. Pelletier thinks that it is sugar combined with solalin.

2. Solanina; Solanìa; Solainie. Symbol So. Formula C_9H_8N,O_3. Eq. Weight 181? — This alkaloid has been discovered in several species of Solanum; viz. S. Dulcamara, S. tuberosum, S. nigrum, and S. verbascifolium. It resembles sulphate of quinia, but its needle-like crystals are finer and shorter. It restores the blue colour of litmus paper reddened by an acid. It dissolves

---

1 Mr. Snee (London Medical Gazette, N. S. vol. i. Feb. 23, 1839), in his paper, "On the Formation of Moulding Tablets for Fractures," says, that "a mixture of carbonate of lime with the solution of dextrine made a composition which answered very well," but it was not equal to a composition of gum and whiting.

3 Sprengel, op. cit. p. 319.

4 Journ. de Pharm. t. v. ii. p. 411.

5 Surbieran, Traité de Pharm. t. ii. p. 52.

6 Hist. Rei Herb. vol. i. p. 227.

8 Journ. de Pharm. vii. 416.
in acids, and is precipitated from its solution by the caustic alkalies. Some of the salts (as the acetate and hydrochlorate) have a gummy appearance when evaporated to dryness; others (as the phosphate and sulphate) are crystalizable. Iodine strikes a characteristic turbid brown colour with a solution of solanina or of its salts, owing to the formation of the insoluble brown iodide of solanina. If Blanchet's analysis be correct, solanina differs from the other vegetable alkalies in the small quantity of nitrogen which it contains, and in its very high atomic weight. A grain of solanina, dissolved in dilute sulphuric acid, killed a rabbit in six hours; four grains of the sulphate caused, in an hour, paralysis of the hind legs; and, in eight hours, death. Soubeiran says it does not dilute the pupils like the other alkalies of Solanaceae.

CHEMICAL PROPERTIES.—A strong decoction of dulcama is slightly darkened by tincture of iodine. Iodide acid had no effect on it. Iodide of potassium rendered it feebly yellow. Tincture of galls had no effect.

PHYSIOLOGICAL EFFECTS.—Not very obvious. Its decoction operates as a diaphoretic and diuretic. It is said also to promote secretion from the mucous surfaces, and to diminish sensibility. In excessive doses, dulcama is stated to have acted as an aero-narcotic. Chevalier says a young man experienced narcotism from carrying a bundle of the plant on his head. But the accuracy of all these observations has been called in question by Jos. Frank, by Dunal, and by Fages. The first gave the decoction, the latter the extract and fruit, in very large doses, without any obvious effects.

USES.—Dulcamara has been thought serviceable in chronic pulmonary catarrhs, in rheumatic and gouty complaints, in chronic skin diseases, and in various cachectic conditions of the system, in which sarsaparilla has been found beneficial. As a remedy for lepra, it was introduced to the notice of British practitioners by Dr. Crichton. For this disease, it has been declared a most effectual remedy by Bate-man, while Rayer speaks of its good effects in eczema and psoriasis. In the few cases in which I have tried it, it proved useless.

DECOCTUM DULCAMARE, L. E. D. [U. S.]; Decoction of Bittersweet.—(Dulcamara, sliced [chopped down, E.], \( \frac{3}{5} \) x \( \frac{3}{5} \), E. [U. S.]; \( \frac{5}{3} \), D.]; Water [Distilled, L.] Oij [\( \frac{3}{3} \), E.; Oss., D.; Ojss., U. S.]. Boil [down to a pint, L. E.; for ten minutes, D.] and strain.—Diaphoretic and diuretic. The usual dose stated in books is \( \frac{3}{5} \) as to \( \frac{5}{3} \). But I have given \( \frac{3}{5} \) for a dose. Rayer has given four ounces of the root in decoction in twenty-four hours.

177. Solanum nigrum, Linna.—Black Nightshade.

Sex. Syst. Pentandria, Monogyinia. (Herba.)

Solanaceae, Dioscorides (lib. iv. cap. 71); Common or Garden Nightshade—Stem herbaceous, with tubercled angles; a foot or more high. Leaves ovate, obusely dentate or wavy, attenuated below. Flowers lateral, drooping, sometimes with a musky scent; corolla white. Berries globular, black, or rarely green when ripe. Indigenous: waste grounds. No complete analysis of it has been made. Desfosses has found maïate of solanina in the fruit. Black nightshade possesses narcotic properties, but its powers appear to be neither great nor uniform. Its emanations are said to be soporific; and in Bohemia, a handful of the fresh plant is sometimes placed in the cradles of infants to promote sleep. In England, this plant has been employed as a resolvent. Smith says, a grain or two of the dried leaf has sometimes been given to promote various secretions, possibly, he adds, by exciting a great and rather dangerous agitation in the viscera.

10 Gataker, Obs. on the Use of Solanum, 1757; Bromfield, Account of the Engl. Nightshades, 1757.
178. CAPSIUM ANNUUM, Linn.—et C. FASTIGIATUM, Blume.

Sex. Syst. Pentandria, Monogynia. (Capsicum Fastigiatum, Bl.—Fructus, L.—Fruit of Capsicum annuum and other species; Capsicum or Chillies, E.—Capsicum annuum; the fruit, D.)

HISTORY.—The *piperitis* or *siliquastrum* of Pliny,¹ is declared by Sprengel² to be undoubtedly Capsicum annuum. But confidence in this opinion is greatly diminished by the doubt entertained as to this plant being a native of Asia.³ Of course, if it be exclusively a native of America, there is no reason for supposing that Pliny could have been acquainted with it. Fraas⁴ considers it to have been Capsicum longum, DC., which Theophrastus⁵ terms *πέπρος ἀπόμυξις*. The term capsicum (καπσικος) occurs first in Johannes Actuarius.

BOTANY. Gen. Char.—Calyx 5—6-cleft. Corolla hypogynous, rotate; tube very short; limb plaited, 5—6-cleft. Stamens 5—6, inserted in the throat of the corolla, exserted; filaments very short; anthers connivent, dehiscing longitudinally. Ovary 2,—3,—4-celled; the placenta adnate to the base of the dissemination or central angle. Style simple, subclavate; stigma obtuse, obsoletely 2—3—lobed. Berry juiceless, polymorphous, incompletely 2—3—celled, placenta deliquescent superiorly. Seeds many, reniform; embryo within fleshy albumen, peripherical, hemicyclical (Endlicher).

Herbaceous annual, 1 to 2 feet high. Leaves ovate or oblong, acminate, long-stalked, almost entire, sometimes hairy on the veins underneath. Flowers white. Berry scarlet, yellow, variegated with red and yellow, or dark green; variable in shape, being oblong, round, or cordate.

2. CAPSIUM FASTIGIATUM, Blume, Bijdr. 705, L.; C. frutescens, Linn. Sp. Pl. but not Hist. Cliff. Frutescent; branches tetragonal, fastigiate, diverging, pubescently sebarous; fructiferous calyx, subcylindrically truncate; fructiferous peduncles, generally twin, erect; berry, oblong-cylindrical, straight; leaves oval or lanceolate, acuminated at both ends, minutely and serrulately ciliated.—India. Shrub 1 or 2 feet high.

DESCRIPTION.—1. The dried fruit, sold by druggists as chillies (*fructus vel baccae capsici annui*), is flat, more or less shrivelled, oblong, blunt or pointed at one end, while the calyx or stalk is usually attached at the other end. The length of the berry (independent of the stalk) is two or three inches, the breadth one-half to three-quarters of an inch, the colour yellowish or reddish-brown, the taste hot and pungent, the odour none. The epidermis is tough and leathery; the seeds are flattened and whitish. The recent fruit, called *capsicum* or *chillies*, grown in this country, and sold for pickling, is, when ripe, yellow or red, but it is frequently gathered green; its size and shape are variable, and it is distinguished as long-podded, short-podded, and heart-shaped.

2. The capsules sold by druggists as Guinea pepper (*Capsicum Guineense*, L.) or bird pepper (*baccae capsici*) do not exceed an inch in length, and are about two or three lines broad; their colour is orange-red, their odour aromatic and pungent. Their properties are similar to those of chillies, than which they are much hotter and more fiery. Their powder is *Cayenne pepper*, so extensively employed as a condiment. On comparing these fruits with those of *C. frutescens*, Linn., in the East Indian Solanaceae belonging to the Linnaean Society, they appeared to me to be identical. But in the *London Pharmacopoeia*, 1851, they are referred to *C. fasti*

giatum, Blume, which is identical with one of the plants described by Linnaeus as C. frutescens. It deserves notice, however, that the commercial fruit is brought from Western Africa, where C. fastigiatus has not hitherto been found. In the Niger Flora, Sir W. Hooker gives C. frutescens, Var. and Linn. Sp. Pl. p. 271, as having been found by Vogel on the Island of St. Antonio.

Besides the above, several other species of Capsicum are employed dietetically and medicinally.

Oblong-cylindrical, straight, less than an inch in length.—Pharm. Loud.

Capsicum chamaeforme, Wild.—The fruit of this species is called cherry chilly or cherry pepper. It is small, round, and cherry-shaped.

Capsicum grossum, Linn.; Bell Pepper.—Fruit large, oblong or ovate, red or yellow.

COMPOSITION.—The fruit was analyzed, in 1810, by Maurach,1 in the same year by Bucholz,2 and in the following year by Braconnot.3

Fruit of Capsicum annuum without seeds . 100.0 Fruit of Capsicum annuum . 100.0

Capsicin, Bucholz; Acrid Soft Resin; Acrid Oil, Braconnot.—Obtained by digesting the alcoholic extract in ether, and evaporating the ethereal solution. It is a thick liquid, of a yellowish-red or reddish-brown colour, which becomes very fluid when heated, and, at a higher temperature, is dissipated in fumes. Half a grain of it, volatilized in a large room, causes all who respire the air of the room to cough and sneeze. By exposure to air and light it solidifies. It is de-colored by chloroform. It is slightly soluble in water and in vinegar; but very much so in alcohol, ether, oil of turpentine, and the caustic alkalies. With baryta it forms a solid acid combination.

PHYSIOLOGICAL EFFECTS.—Capsicum belongs to the spices (see vol. i. p. 253), and is more closely allied, by its effects, to the peppers (see ante, p. 351) than to any other article of the Materia Medica. Sundelin,4 however, considers it to be more related to pyrethrum. Its active principle is more fixed, and its operation is more permanent and violent, than mustard or horseradish.

Its hot and fiery taste is familiar to every one. Applied to the skin, capsicum proves rubefacient and vesicant. Swallowed in small doses, it creates a sensation of warmth in the stomach; and in torpid and languid habits proves a valuable stimulant, and a promoter of the digestive functions. Taken in somewhat larger quantities, it produces a glow over the body, excites thirst, and quickens the pulse; the latter effect, however, is not in proportion to its local effect. Like the peppers, it is said to exercise a stimulant influence over the urino-genital organs. In excessive doses we can easily believe that vomiting, purging, abdominal pain, and gastric inflammation, ascribed to it by Vogel,5 may be induced by it, though I am not acquainted with any cases in which these effects have occurred. Richter6 mentions, in addition to the symptoms just mentioned, a paralyzed and altered condition of the nervous influence, an affection of the head, drunkenness, and giddiness, as being produced by large doses.

USES.—Capsicum is more employed as a condiment than as a medicine. It is added to various articles of food, either to improve their flavour, or, if difficult of digestion, to promote their assimilation, and to prevent flatulence. The inhabitants of tropical climates employ it to stimulate the digestive organs, and thereby to counteract the relaxing and enervating influence of external heat.

As a medicine, it is principally valuable as a local stimulant to the mouth, throat,

1 Bell Jahrb. Bd. xvi. S. 63.
3 Pharmacody. Bd. ii. S. 581, 3te Aufl.
5 Handb. d. sp. Heilim. Bd. ii. S. 84, 3te Aufl.
and stomach. Its constitutional not being in proportion to its topical effects, it is of little value as a general or diffusible stimulant. Administered internally, capsicum has long been esteemed in cases of *cynanche maligna*. It was used, in 1786, with great success by Mr. Stephens and by Mr. Collins. It promoted the separation of the sloughs, and soon improved the constitutional symptoms. Mr. Headby also employed it both internally and by way of gargle. Its use has been extended to *scarlatina anginosa*. As a gargle, in relaxed conditions of the throat, its efficacy is undoubted. The powder or tincture may be applied, by means of a camel-hair pencil, to a relaxed uvula. It is a very useful gastric stimulant in enfeebled, languid, and torpid conditions of the stomach. Thus in the dyspepsia of drunkards, as well as of gouty subjects, it has been found useful. In various diseases attended with diminished susceptibility of stomach, capsicum is an exceedingly useful adjunct to other powerful remedies, the operation of which it promotes by raising the dormant sensibility of this viscera; as in cholera, intermittents, low forms of fever, dropsies, &c. Dr. Wright speaks in high terms of it as a remedy for obviating the black vomit—a symptom of the fever of tropical climates, at one time considered fatal. A capsicum cataplasm may be used with advantage to occasions, rubefaction in any cases in which a rubefacient counter-irritant is indicated; as in the coma and delirium of fever, in chronic rheumatism, &c.; unless kept on for a long period it does not vesicate.

**Administration.**—The powder of capsicum is usually given in doses of from gr. v to gr. x, made into pills with crumbs of bread. The dose of the tincture will be mentioned presently. The *infusion* (prepared by digesting 3ij of capsicum in 15j of boiling water for two hours) may be administered in doses of 3ss. But, in malignant sore-throat and scarlatina, capsicum has been employed in much larger doses. Stephen’s *pepper medicine* consisted of two table-spoonfuls of small red pepper, or three of the common Cayenne pepper, and two teaspoonfuls of fine salt, digested in half a pint of boiling water. To the liquor, strained when cold, half a pint of very sharp vinegar is added. A table-spoonful of this mixture is to be given to an adult every half hour. The *capsicum gargle* is prepared by infusing 3ss of capsicum in a pint of boiling water; or by adding 15vj of the tincture to 15viij of the infusion of roses; or, in some cases, Stephen’s pepper medicine may be used as a gargle.

**Tinctura Capsici, L. E. D. [U. S.]; Tincture of Capsicum.**—(Capsicum, bruised [or, if percolation be followed, in moderately fine powder, E.], 3x [3iss, D.]; Proof Spirit Oij [Oij, D.]. Digest for seven [fourteen, D.] days, then express and strain [strain, squeeze the residuum, and filter the liquors. [The *U. S. Pharm. directs* Capsicum, in powder, 3i; Diluted Alcohol Oij.] This tincture is best prepared by percolation, which may be commenced so soon as the capsicum is made into a pulp with a little of the spirit, E.].—Dose 1x to 15j. Employed in the low stage of typhus and scarlet fevers, and in gangrenous sore-throat, and to prevent the nausea which oil of turpentine is apt to occasion. Properly diluted, it may be used as a gargle, as above mentioned. Externally, it is sometimes used as a local stimulant.

### 179. Mandragora Officinarum, Linn.—Common Mandrake.

**Sxx. Syst. Pentandria Monogynia.**

(Radix.)

---

resemblance to the human form, were called anthropomorphon, and were supposed to prevent barrenness. The root of Bryonia dioica is sold at the herb-shops as a substitute for Mandrake. Dr. Sylvester has recently drawn attention to the ancient uses of this plant as an anesthetic.

ORDER XLIII. BORAGINACEÆ, Lindley.—BORAGEWORTS.

Borragewort, DC.—Boraginaceæ, Endl.

Characters.—Calyx persistent, with 4 or 5 divisions. Corolla hypogynous, monopetalous, generally regular, 5 cleft, sometimes 4-cleft, with an imbricated activation. Stamens inserted upon the corolla, equal to the number of its lobes, and alternate with them. Ovary 4 parted, 4-seeded, or 2-parted, 4-celled; ovules attached to the lowest point of the cavity, amphitropical. Style simple, arising from the base of the lobes of the ovary; stigma simple or bifid. Nuts 2 or 4, distinct. Seed separable from the pericarp, destitute of alumen; embryo with a superior radicle; cotyledons parallel with the axis, plano-convex, sometimes 4 (!) in Amsiuckia.—Herbaceous plants or shrubs. Stems round. Leaves alternate, often covered with asperities consisting of hairs proceeding from an indurated enlarged base. Flowers in 1-sided gyrate spikes or racemes, or panicles, some solitary and axillary (Lindley).

Properties.—The plants of this order are characterized by their mucilaginous quality; they are therefore, mostly harmless and inert.

Formerly, several borageworts were used in medicine; for example, Symphytum officinalis, Linn., Borrago officinalis, Linn. Cyanobosum officinale, Linn., Lithospermum officinale, Linn., Alkanna tinctoria, Linn. Tree, with medicinal value (though formerly many virtues were ascribed to them), and are now obsolete. The only boragewort still found in pharmacists' shops is Alkanna tinctoria, Linn.

180. Alkanna tinctoria, Tausch.—Dyer's Alkanet.

Sex. Syst. Pentandria, Monogynia. (Radix.)

*Ayurveda, Dioscorides, lib. iv. cap. 23; Lithospermum tinctorium, Linn., Herb. Sp. ed. i. non. ed. ii.; Anacissus tinctoria. 3 Desf. Atl. i. p. 156; Hayne, Arzneigew., 10, t. ii.; Alkanna tinctoria, Nees, Off. Pflanz., Suppl. ii. t. 6; Handb. ii. 591; Alkanna tinctoria, Tausch, in Florâ, 1824. A deciduous herbaceous plant with a perennial, dark-blue-red root. This, when dried, constitutes the alkanet root (radix alkanneae tinctoriae) of the shops, and which is sometimes called spurious alkanet root (radix alkanneae spuriae) to distinguish it from the henna or al-henna of the Arabs (Lawsonia alba, Lam.), whose root is called the true alkanet (radix alkanneae vera). The plant grows on the shores of the Mediterranean, in Asia Minor, Greece, &c.

Alkanet root was analyzed by John, who found the constituents to be a peculiar colouring matter (pseudo-alkamin) 5.50, extractive 1.00, gum 6.25, matters extracted by caustic potash 65.00, woody fibre 18.02=95.75 [less 4.25]. The colouring matter resides in the cortical part of the root, and was regarded by Pelliet as a kind of fatty acid (Anchusia acid) but now is usually considered to be a resinoid (Anchusine) whose composition is C29H43NO8. It is of a dark red colour, fusible at 140° F., insoluble in water, but very soluble in alcohol and in acetic acid. The alkalis colour it blue. Acetate and subacetate of lead, protochloride of tin, the salts of iron and alumina, precipitate it; chloride and strong acids destroy it. Alkanet root communicates its colouring matter to oil and fatty substances; and hence is used by the pharmacist to colour lip salve (unguentum labiale), hair oil, &c.

ORDER XLIV. CONVOLVULACEÆ, R. Brown.—BINDWEEDS.

Convolvuli, Jussieu.

Characters.—Calyx persistent, in 5 divisions, remarkably imbricated, as if in more whorls than 1, often very unequal. Corolla monopetalous, hypogynous, regular, deciduous; the limb 5 lobed, plaited; the tube without scales. Stamens 5, inserted into the base of the corolla, and
alternate with its segments. Ovary simple, with 2 or 4 cells, seldom with 1; sometimes in 2 or 4 distinct divisions; few-seeded; the ovules definite and erect, when more than 1 collateral; style 1; usually divided at the top, or as many as the divisions of the ovary, and arising from their base; stigmas obtuse or acute. Disk annular, hypogynous. Capsule with from 1 to 4 cells, succulent or capsular; the valves fitting, at their edges, to the angles of a loose dissepiment, bearing the seeds at its base. Seeds with a small quantity of mucilaginous albumen; embryo curved; cotyledons leafy, shrivelled; radicle inferior next to the hilum. Herbaceous plants or shrubs, usually woody and milky, smooth, or with a simple pubescence; sometimes erect bushes. Leaves alternate, undivided or lobed, seldom pinnatifid, with no stipules. Inflorescence axillary or terminal; peduncles 1 or many-flowered, the partial ones generally with 2 bracts, which sometimes enlarge greatly after flowering (Lindley).

Properties.—The roots and seeds only have been used in medicine.

The tuberous roots of some species (as of jalap and scammony) contain an acrid, milky, purgative juice, which owes its medicinal qualities to the contained resin. Mechoan and Turpethum (Iponema Turpethum) roots, formerly used as purgatives, are now obsolete. In other tuberous roots (as of Batatas edulis) the resin is deficient or absent, and starchy matter predominates; in consequence of which they become edible, and are cultivated for the table.

The seeds of some species (as of Pharbitis carnea) are cathartic.

181. CONVOLVULUS SCAMMONIA, Linna.—THE SCAMMONY.

Sex. Syst. Pentandria, Monogyonia. (Gummi-resina e recepta radice emissa, L. D.—Gummy resinous exudation from incisions into the root, E. D.)

History.—A purgative substance called scammony (σκαμμόνιον) was known to the Greeks long before the time of Hippocrates. The Father of Medicine, who frequently employed it, says that it evacuates, both upwards and downwards, bile and mucus, and expels flatus. Dioscorides notices the plant which yields scammony, and terms it σκαμμόνια. Pliny, also, speaks of scammony, which he calls scammonium.

Dr. Sibthorp refers the scammony of Dioscorides to C. furinaceus, a Maderia species! on what ground does not appear, as this supposed species is not in his herbarium. If the ordinary reading of the text of Dioscorides be correct, this author represents the scammony as having hairy branches and leaves; which applies better to C. sagittifolius (C. Sibthorpii, Roemer and Schultes), found by Sibthorp in Samos and other islands of the Grecian Archipelago. This species is with great probability adopted by Dierbach as the source of the ancient scammony.

Sp. Char.—Stem smooth. Leaves sagittate, posteriorly truncate with entire or elongated slashed auricles. Peduncles very long, many-flowered. Sepals coloured, ovate, obtusely truncated, mucronulate, the external ones a little smaller, 2—3 lines long. Corolla campanulate, an inch long (Choisy).

Root perennial, tapering, 3 or 4 feet long, with an acrid, milky juice. Stems numerous, twining, herbaceous, smooth. Leaves on long petioles, acuminate, with pointed lobes at the base. Peduncles solitary, scarcely twice so long as the leaves. Bracts awl-shaped. Sepals obovate, truncated, with a reflex point, coloured at the edge. Corolla pale yellow, with purple stripes. Stamens shorter than the corolla; anthers erect, sagittate. Style as long as the stamens; stigmas white.

Hab.—Hedges and bushy places in Greece and the Levant.

Preparation.—The method of procuring scammony is, according to Dr. Russel, 8

---

5 Lindley, Fl. Medica.
7 Tournefort (Voyage into the Levant, vol. ii. p. 96, 1741) says that the scammony of Samos is collected from a bindweed (convolvulus) whose leaves are larger, hairy, and slashed at their basis not so prettily as those of the Syrina scammony (C. scammonia). This doubtless is C. sagittifolius, which Sibthorp found in Samos.
8 Med. Obs. and Inv. vol. i. p. 12, 1776.
as follows: Having cleared away the earth from the upper part of the root, the peasants cut off the top in an oblique direction, about two inches below where the stalks spring from it. Under the most depending part of the slope they affix a shell, or some other convenient receptacle, into which the milky juice flows. It is then left about twelve hours, which time is sufficient for the drawing-off the whole juice; this, however, is in small quantity, each root affording but a few drachms. This milky juice from the several roots is put together often into the leg of an old boot, for want of some more proper vessel, when in a little time it grows hard, and is the genuine scammony.

Of this entirely pure scammony, says Dr. Russel, but very little is brought to market, the greater part of what is to be met with being adulterated, if not by those who gather it, by those who buy it of them abroad; for the chief part of what is brought hither passes through the hands of a few people, chiefly Jews, who make it their business to go to the villages of any note near which the scammony is collected (as Antioch, Shogre, Elib, Maraash, &c.), and then buying it while it is yet soft, they have an opportunity of mixing it with such other things as suit their purpose best—as wheat-flour, ashes, or fine sand, all of which he found it mixed with; but there seems, he adds, some other ingredient (possibly the expressed juice), which makes it so very hard and indissoluble that he was not able to discover it to his satisfaction.

 Dioscorides thus describes the mode of procuring it: The head being separated, the root is to be excavated in the form of a dome (or vault) by a knife, so that the juice may flow into the cavity, from which it is to be taken out in shells. Others excavate the earth, and, having incised the root, let the juice run into the cavity, which has been previously lined with walnut leaves; when the scammony is dry, it is removed.

I have been informed by a Turkey merchant, who formerly resided at Smyrna, that scammony is brought into Smyrna, in the soft state, on camels. Here it is mixed with various impurities by persons (Jews) who are denominated scammony-makers, and who adulterate it, and thereby lower its value to suit the market.

DESCRIPTION.—Scammony (scammonium; gummi-resina scammonii) is usually imported from Smyrna. Occasionally, it comes by way of Trieste. Still more rarely it is brought from Alexandria (also called Scanderoon or Iskenderun), the port of, and road to, Aleppo. It comes over in boxes and drums, which are frequently lined with tin.

1. I shall arrange the different sorts of scammony of commerce under three heads: 1st, pure scammony; 2dly, adulterated scammony; 3dly, facitious scammony.

1. Pure Scammony (Scammonium purum).—In English commerce one sort only is known under this name—namely, the virgin scammony. Scammony in shells is probably a pure scammony, but is unknown in trade. Trebizion or Samos scammony, though perhaps a pure scammony, differs so much in its external appearance from the ordinary commercial sorts, that it is unsalable here.

a. Virgin Scammony (Lacryma; Scammony; Superior Aleppo Blackish

* Marquart (Pharm. Central-Blatt für 1837, p. 671), who has published an elaborate paper on scammony. He arranges the various sorts as follows:—

1. Scammony from the Convolvulaceae.—Under this head he includes
   a. Aleppo scammony. Of this he makes five sorts.
   b. Antioch scammony. Of this he makes three sorts.
   c. Samos scammony.

2. Scammony from the Asclepiadaceae.
   d. French or Montpellier scammony.

3. Scammony from the Apocynaceae.
   e. Smyrna scammony of commerce. Of this he makes four sorts.

But the foundation of this arrangement is erroneous. Smyrna scammony is not the produce of Apocynaceae, but of a smooth-leaved Convolvulus; as Sheard (Geoffroy, Traité de Mat. Med. ii. 667) has shown. Under the head of Smyrna scammony, Marquart includes adulterated and facitious commercial sorts. In English commerce no distinction of Aleppo, Antioch, and Smyrna scammony is made.

2. The term "lacryma scammony" I have heard applied to this sort of scammony by a "Turkey merchant. It is remarkable that a somewhat similar term was used by the ancients. Cælius Aurelianus (Ant. Mord. lib. ii. cap. xxix.) speaks of " lacrima scammoniae quam diangriatis appellanum." Now diangridium is a corruption from δια'γριδις, lacrymula, a little tear. The word diangridium was also applied to a preparation of scammony.
Scammony, (Guib.) — It usually occurs in amorphous pieces; but a careful examination of some large lumps has led me to believe that they formed portions of a mass, which, when in the soft state, had a rounded form. The whitish-gray powder, which covers some of the pieces, effervesces with hydrochloric acid; and I have no doubt, therefore, that the masses have been rolled in chalk. Virgin scammony is friable, easily reduced to small fragments between the fingers, or by the pressure of the nail, and has, according to my experiments, a sp. gr. of 1.210. Its fractured surface is resinous, shining, greenish-black; presents small air-cavities, and numerous gray semitransparent splinters, or fragments, when examined by a magnifying glass; and does not effervesce on the addition of hydrochloric acid. When rubbed with the finger moistened with ether, water, or saliva, it readily forms a milky liquid. If we examine thin fragments, or splinters, by transmitted light, we observe them to be semitransparent at the edges, and of a gray-brown colour. In the same piece we sometimes find some portions shining and blackish, as above described; while others are dull grayish. This difference depends probably, as Dr. Russel has suggested, on different methods of drying. Virgin scammony readily takes fire, and burns with a yellowish flame. Its odour is peculiar, somewhat analogous to old cheese; its taste is slight at first, afterwards acid. The decoction of its powder, when filtered and cold, is not rendered blue by tincture of iodine. When incinerated in a crucible, it leaves a minute portion only of ash.

This sort of scammony is usually imported from Smyrna.

Porous, brittle, glistening on the fractured surface; emits no bubbles when hydrochloric acid is dropped on it; no blue colour is produced by the simultaneous addition of iodide of potassium and dilute nitric acid to water, in which powdered scammony has been digested at 170°. Ether should dissolve 78 grains out of 100 grains of scammony, L.

b. Scammony in shells or calebasses (Scammonium in testis; Sc. in calebasis).—Unknown in English commerce. It is described by continental writers as a very pure sort.

γ. Trebizon Scammony.—In 1832, a substance was imported into London, from Trebizon, under the name of scammony, which was unsalable here. The sample which I received is a portion of cake apparently round, flat below, and convex above. Its colour is light-grayish or reddish-brown; when moistened, the surface becomes glutinous and odorous; its taste is sweet, nauseous, and somewhat bitter. In its external appearance it has more resemblance to benzoin than scammony.

This, probably, is the Scammony of Samos mentioned by Tournefort; the Scammony from Myria of Dioscorides. It would appear to be obtained from a species of Convolvulus (C. Sagittifolius) different from that which yields the Aleppo and Smyrna scammony; for both Dioscorides and Tournefort state that the leaves are hairy.

2. ADULTERATED SCAMMONY (Scammonium adulteratum).—Under this head are included the various sorts of scammony commonly found in the shops, and which English dealers distinguish as seconds, thirds, &c. To this division belongs the so-called Antioch scammony (scammonium antiochum) of continental writers. What is sometimes called on the continent Smyrna scammony (scammonium Smyrnense), is either adulterated or factitious scammony. The term Aleppo scammony (scammonium halepense seu aleppicum) is applied by the same writers to virgin scammony, and to the better sorts of adulterated scammony. The different sorts of adulterated scammony more frequently occur in round flattened or plano-convex cakes of variable size, usually an inch or two in thickness, and about five inches in diameter. Some are met with in amorphous, irregular lumps; others in large cylindrical or drum-shaped masses.

The different sorts of adulterated scammony vary considerably in appearance, but pass so insensibly the one into the other that it is impossible to classify them according to their physical characters. I shall, therefore, arrange them according to their chemical characters.

A. Adulterated Scammony, which effervesces on the addition of hydrochloric

---

2 I have a specimen of scammony, sent to a friend of mine for sale from Aleppo, which is so adulterated that no offer can be obtained for it. It is in thin flat cakes, which have a sweet smell, and contain the starch of either wheat or barley—probably of the former.
acida.—This is characterized by the presence of carbonate of lime, and sometimes with starch or dextrine also.

a. *Calcareaous, Chalky, or Cretaceous Scammony.*—Occurs in round flat cakes, or in irregular lumps. It is more ponderous than the virgin sort, and usually breaks with a dull and earthy fracture. Its' colour is ash-gray, like common secondary limestone. A specimen in irregular lumps I found to have the sp. gr. of 1.463.

Its chemical characters are as follows: hydrochloric acid applied to a fractured surface causes effervescence; iodine produces no change of colour when added to the filtered decoction after it has become cold.

Lumps of crystallized carbonate of lime are sometimes found in this sort of scammony.

b. *Calcarea-Amylaceous Scammony.*—This, like the preceding, occurs in round flat cakes or in irregular lumps, which contain carbonate of lime and either wheat or barley starch or meal.1 I have also met with it in cylindrical or drum-shaped masses.

aa. *In irregular lumps.*—It sometimes resembles pure scammony in its glossiness and dark resinous appearance; but usually it has a waxy lustre and grayish colour.

β3. *In cylindrical or drum-shaped masses.*—This kind is imported either in boxes or drums, into which it seems to have been introduced when soft, and to have hardened subsequently—hence its form is that of the package in which it was imported. A sample of a circular cake (about 12 inches in diameter, and several inches thick) presents a dull-grayish fracture. Its sp. gr., according to my experiments, is 1.359.

γγ. *In circular flat cakes.*—I have received this sort of scammony in the form of circular flat cakes, about five inches in diameter, and one inch thick. They are heavy, dense, and much more difficult to fracture than the preceding kinds. The fractured surface, in some samples, is resinous and shining, in others dull; it has air-cavities, and numerous small white specks (chalk); its colour is grayish to grayish-black. The sp. gr. varies, in different samples, from 1.276 to 1.543. I have received portions of five cakes of this variety of scammony, on which were marked the actual quantity of chalk which had been intermixed in each sample. In 100 parts of the cakes the proportions of chalk were respectively as follows: 13.07, 23.1, 25.0, 31.05, and 37.54. These numbers were furnished by the Levant importer to one of our most respectable wholesale druggists, from whom I received them.

The chemical characters of calcareo-amylaceous scammony are as follows: hydrochloric acid applied to a fractured surface causes effervescence; iodine produces a blue colour when added to the filtered decoction after it has become cold.

γ. *Calcarea-dextrinous Scammony.*—This sort differs from the preceding in the circumstance that iodine produces a reddish-purple tint when added to the filtered decoction after it has become cold. It appears to contain carbonate of lime and dextrine.

B. *Adulterated Scammony, which does not effervescence on the addition of hydrochloric acid.*—This sort of scammony is usually sophisticated with wheat-meal.

8. *Amylaceous Scammony.*—This sort of scammony is adulterated with the starch or flour of either wheat or barley—probably the former; it is of less frequent occurrence than the calcareo-amylaceous kind. It occurs in irregular lumps and round flat cakes, which sometimes have a resinous fracture and a dark colour

---

1 Dioscorides states that the Syrian scammony is adulterated with *εὐθύμαρας* (Euphorbia or spurge) and *εὐθύμον ξίωμα* (meal of the ereill or bastard lentil, the *Eruvum Ervilia* of Linn.). A careful microscopic examination of amylaceous and calcareo-amylaceous scammony has satisfied me that the starch of flour used for adulterating these sorts of scammony, at the present day, is that of either wheat or barley—i.e. I think of wheat.
like pure scammony, but which more commonly have a waxy lustre and a grayish colour. It contains starch and ligneous matter, but not chalk. It does not, therefore, effervesce with hydrochloric acid. Its decoction, when filtered, and cooled, strikes a blue colour on the addition of iodine.

1. Selenitic or Gypseous Scammony.—This kind has been described by Marquart. Its sp. gr. was 1.731, and it contained no less than 52 per cent. of gypsum (sulphate of lime).

7. Bassorin Scammony.—Marquart met with a scammony which had a horny consistence and a sp. gr. of 1.167. After it had been deprived of its resin and extractive, it swelled up in boiling water. The constituent which thus swelled up was soluble in caustic potash; Marquart regarded it as bassorin.

In the Museum of the Pharmaceutical Society is a specimen of scammony which is supposed to be adulterated with tragacanth and some resin.

4. Indian Scammony.—From my friend Dr. Royle I have received a sample of scammony met with in the Indian bazaars. It is light, porous, of a greenish-gray colour; gritty under the teeth, as if containing a considerable quantity of sand, and having a balsamic olibanum-like odour.

3. Factitious Scammony (Scammonium factitium).—To this division belongs part of the so-called Smyrna scammony of continental commerce, as well as French or Montpellier scammony. I have met with three samples of factitious scammony.

a. Under the name of Smyrna scammony, I purchased of a London dealer a sort of scammony in the form of circular flat cakes, about half an inch thick. It is blackish, and has, externally, a slaty appearance; it breaks with difficulty; its fracture is dull and black. Its sp. gr. is 1.412. Moistened and rubbed, it evolves the smell of guaiacum. Boiled with water, it yields a turbid liquor (which is not rendered blue by iodine), and deposits a blackish powder; the latter, boiled with alcohol, yields a solution which becomes greenish-blue on the addition of nitric acid, showing the presence of guaiacum.

It is probably the common Smyrna scammony (Scammonium myrsyneum factitium) of Gray, who directs it to be made with Aleppo scammony, 1 lb.; extract of jasap, 5 lbs.; guaiacum resin, 10 lbs.; sago, 10 lbs.; and ivory black, 4 lbs.

b. Under the name of Scammonium myrsyneum medicinale venale, M. Batka has presented to the Pharmaceutical Society a spurious scammony said to be made up of gum, bread, scammony, guaiacum, benzoin, wax, sand, and wood.

c. French or Montpellier Scammony (Scammonium gallicum seu monspeliacum).—This substance is made, in the southern part of France, with the expressed juice of Cynanchum monspeliacum, mixed with different resins and other purgative substances. It occurs in semicircular, blackish, hard, compact cakes, which frequently have the smell of balsam of Peru.

COMPOSITION. a. Of the Root.—The dried root of Convolvulus Scammonia was analyzed, in 1837, by Marquart, who obtained from it the following substances: resin 4.12, sugar, convolvulin, and extractive 18.68, resin and wax 0.55, gum, 5.8, extractive 2.4, starch 7.0, extractive soluble in hot, but not in cold water 1.4 [salsis et woody fibre 65.05]. The resin, the wax, and a portion of the gum, are contained in the milky juice of the latex vessels (exsula laticis); while the sugar, gum, extractive, and salts dissolved in water, constitute the juice of the cells; and in this juice the starch-globules float.

1. Resin.—This is analogous to that of the scammony of commerce.

2. Convolvulin.—A substance supposed by Marquart to be a vegetable alkalii. It reacts feebly as a vegetable alkali, and is precipitated from its watery solution by tincture of nutgalls. Marquart thinks it probably exists in jasap.

b. Of Scammony.—Bouillon-Lagrange and Vogel analyzed two kinds; one called Aleppo, the other Smyrna scammony. Marquart analyzed twelve kinds; of these, eight sorts (five called Aleppo, and three Antioch scammony) he considers to be the produce of Convolvulus Scammonia; while the remaining four, which, he says, are called in commerce Smyrna scammony, he erroneously ascribes to Periploca Secamone, Linn. Three of these, however, appear to be adulterated sorts, and one (the 12th) is obviously factitious.

**Adulteration.**—The characters of good scammony are as follows: It readily fractures between the fingers, or by the pressure of the nail; its ep. gr. is about 1.2; its fracture is dark, glistening, and resinous; its fractured surface should not effervescce on the addition of hydrochloric acid; the decoction of the powder, filtered and cooled, is not rendered blue or purplish by tincture of iodine; paper moistened with an alcoholic or ethereal tincture of scammony should undergo no change of colour when exposed to brown nitrous fumes (produced by pouring a drachm of strong nitric acid over some filings of zinc, iron, or copper, contained in a tumbler or wineglass); 100 grains, incinerated with nitrate of ammonia, yield about three grains of ashes (according to my experiments); sulphuric ether separates at least 78 per cent. of resin (principally), dried at 280° F.

"Fracture glistening, almost resinous, if the specimen be old and dry; muriatic acid does not cause effervescence on its surface; the decoction of its powder, filtered and cooled, is not rendered blue by tincture of iodine. Sulphuric ether separates at least 80 per cent. of resin dried at 280°."—*Ph. Ed.*

Hydrochloric acid detects the presence of carbonates; iodine added to the cooled decoction of scammony detects starch and dextrine; by nitrous fumes the presence of guaiacum resin may be detected, for they give a blue colour to paper which has been moistened with tincture of guaiacum; incineration detects an abnormal amount of inorganic matter, as chalk, gypsum, or sand; ether determines the amount of resinous matter present.\(^6\) The microscope serves to detect the presence and sort of starch or meal used for adulterating. Hitherto, the only starch I have detected in adulterated scammony is that of a cereal, either wheat or barley—probably the former (see ante, p. 512).

**Physiological Effects.** \(a.\) *On Animals generally.*—The experiments of Orfila\(^4\) lead us to infer that scammony is not poisonous. "We have," says he, "frequently administered four drachms of it to dogs who had the oesophagus afterwards tied, and have only observed alvine evacuations." On horses and other herbivorous animals its operation is very uncertain. Gilbert\(^5\) states that six drachms killed a sheep in twenty days, without having caused purging. Viborg\(^6\) says half an ounce given to a dog caused several loose stools; the same dose had no effect on a badger. It is probable, however, that in all the experiments now referred to, adulterated scammony was employed.

\(b.\) *On Man.*—The effects of pure scammony are those of a powerful and drastic purgative. As the greater part of the commercial drug is largely adulterated, practitioners are, I suspect, scarcely acquainted with the operation of the genuine article, which appears to me to possess nearly double the activity of that usually

---

\(^1\) Dispensatory.

\(^2\) For further details, see a paper *On the Adulteration of Scammony*, by the author, in the *Pharmaceutical Journal*, vol. iv. p. 307, 1845.

\(^3\) *Toxicol. Gen.*

\(^4\) *Morrou, Pharm. Vé.*, p. 271.
found in commerce. As the evacuant powers of scammony depend on its local irritation, it operates more energetically when there is a deficiency of intestinal mucus, and is then very apt to grippe; and vice versa, when the intestines are well lined with secretion, it passes through with much less effect. In its operation scammony is closely allied to jalap, than which it is more active, while its odour and taste are less nauseous. It is less irritant than gamboge.

Uses.—Scammony is, of course, inadmissible in inflammatory conditions of the alimentary canal, on account of its irritant qualities. It is well adapted for torpid and inactive conditions of the abdominal organs, accompanied with much sliny mucus in the intestines. It is principally valuable as a smart purgative for children, on account of the smallness of the dose necessary to produce the effect, the slight taste, and the energy, yet safety, of its operation. When used for them, it is generally associated with calomel. Where a milder purgative is required, it may be conjoined with rhubarb, sulphate of potash, and an aromatic. It may be employed to open the bowels in constipation; to expel worms, especially of children; to act as an hydragogue purgative, on the principle of counter-irritation, as in affections of the head and dropsies; and for any other purpose for which an active cathartic may be required.

Administration.—For an adult, the usual dose of commercial scammony is ten grains to a scruple; but, of virgin scammony, from ten to fifteen grains. In order to diminish its irritant and gripping qualities, it should be finely divided. For this purpose it may be intimately mixed with some bland powder (as gum, starch, sugar, &c.), or made into an emulsion with milk.

1. Pulvis Scammonii Compositus, L. D.; Compound Powder of Scammony.—
(The London College directs it to be prepared with Scammony, Hard Extract of Jalap, of each 3j; Ginger 3ss. Rub them separately to very fine powder; then mix them. The Edinburgh College directs it to be made of equal parts of Scammony and Bitartrate of Potash, triturated together to a very fine powder. The Dublin College orders of Scammony, in fine powder, 3j; Compound Powder of Jalap iij. Mix thoroughly by trituration, and pur the powder through a fine sieve.)—The effects of scammony and of extract of jalap being very similar, little or no advantage can be obtained by the intermixture of these substances. The ginger is intended to correct the gripping of the other ingredients. The bitartrate of potash, used by the Edinburgh College, can do little more than serve to divide the scammony. Compound powder of scammony is cathartic; and is used as a smart purge for children, especially where much mucous slime is contained in the bowels, and in worm cases. The dose of the London and Dublin preparation, for an adult, is from grs. x to 3j; for children under a twelvemonth old, from grs. iiij. to grs. v. The dose of the Edinburgh preparation, for an adult, is from grs. xvi to 3ss.

2. Pulvis Scammonii Cum Calomelane; Powder of Scammony with Calomel.—
(Scammony 3j; Calomel, Sugar, of each 3ss. Mix.)—Though this preparation is not contained in any of the British pharmacopoeias, yet the frequency of its employment in the diseases of children is a sufficient apology for its introduction here. Dose, for an adult, grs. x to grs. xx; for children, from grs. iv to grs. x, according to the age of the patient.

This preparation may be employed as a substitute for the old Pulvis Basilicus, or Royal Powder, which consisted of equal parts of scammony, calomel, cream of tartar, and antimoniac acid.

3. Confectio Scammonii, L.; Electuarium Scammonii, D.; Confection of Scammony.—(Scammony, powdered, 3js; Cloves, bruised; Ginger, powdered, each 3vj; Oil of Caraway 15ss; Syrup of Roses as much as may be sufficient. Rub the dry ingredients together to very fine powder, and preserve them; then, whenever the confection is to be used, the syrup being gradually poured in, rub again; lastly, the oil of caraway being added, mix them all, L.—The Dublin College orders of Scammony, in fine powder, iij; Ginger, in fine powder, 3ss; Oil of
Caraway f 5 j; Oil of Cloves f 5 ss; Simple Syrup f 5 iij; Clarified Honey, by weight f 5 iss.)—A warm or aromatic cathartic. Dose, for an adult, f 5 j to f 5 j; for children, grs. iij to grs. x. It is seldom employed.

4. EXTRACTUM sive RESINA SCAMMONII, E.; Extract or Resin of Scammony.—(Take any convenient quantity of scammony in fine powder; boil it in successive portions of proof spirit till the spirit ceases to dissolve anything; filter; distil the liquid till little but water passes over. Then pour away the watery solution from the resin at the bottom; agitate the resin with the successive portions of boiling water till it is well washed; and, lastly, dry it at a temperature not exceeding 240°.)

—To obtain pure resin of scammony, alcohol or ether should be used instead of proof spirit. It is brownish, and in thin layers transparent; when heated, it evolves a peculiar, not disagreeable odour; it is fusible and combustible. It is soluble in alcohol, ether, and oil of turpentine.

Resin of jalap is insoluble in oil of turpentine, and nearly so in ether; whereas scammony resin is readily soluble in these liquids. By these peculiarities the two resins may be distinguished from each other.

The alcoholic solution of scammony resin is feebly acid; the addition of water causes a white precipitate (hydrate of resin). Precipitates (metallic scammoniates?) are also produced by alcoholic solutions of the acetate of lead and the acetate of copper. Caustic potash deepens the colour of the solution. Scammony resin may be decolorized by animal charcoal without having its purgative qualities affected. Its composition, according to Mr. Johnston, is C6H6O3. It is "remarkable for containing the largest quantity of oxygen of any resin hitherto analyzed." (Johnston.) When pure or virgin scammony can be obtained, the resin is an unnecessary preparation. Scammony resin is a drastic cathartic. Dose, grs. viij to grs. xij. When administered, it should be intimately divided, either by some bland powder, or still better by an emulsion.

5. TINCTURA SCAMMONII; Tincture of Scammony; Tincture de Scammoné.—Codex, Pharm. Francaise, 1837.—(Aleppo Scammony 1 part; Rectified Spirit 4 parts by weight; macerate for fifteen days and filter.)—Dose, f 5 ss to f 5 j diffused through a mucilaginous mixture of milk.

6. MISTURA SCAMMONII, E.; Mixture of Scammony.—(Resin of Scammony gr. viij; Unskimmed Milk f 5 iij. Triturate the resin with a little of the milk, and gradually with the rest of it till a uniform emulsion is formed.)—This is an imitation of Planché's purgative potion, except that two drachms of sugar and three or four drops of cherry-laurel' water are omitted. It is one of the most agreeable draughts that can be taken.

182. EXOGONIUM PURGA, Bentham.—TURE JALAP.

Sex. Syst. Pentandria Monogynia.
(Tuber, L. D.—Root, E. D.)

History.—De Paiva4 thinks that Jalap was known to Dodeons in 1552, to Monardes in 1568, and to Clusius in 1574. But Bauhin6 (who calls it Bryonia Mochacana nigricans) says it was brought from India, under the name of Chelapa, or Celapa, about eleven years before the time he wrote (the date of the preface to his work is 1620); that is, about 1609 or 1610. Its name seems to be derived from Xalapa, a town of Mexico.

The jalap plant has been successively declared to be a Mirabilis, a Convallulus, an Ipomoea, and an Exogonium. The Convulsoles Jalapa described and figured by Woodville7 and Desfontaines,8

7. Fiedermann, p. 123.
is now well known to yield none of this drug. The real jalap plant was first described by Mr. Nuttall; but the name (Ipomoea Jalapae) he gave to it had been already applied by Pursh to another plant. In the same year Dr. Schiedea and Dr. Wenderoth noticed it; the latter called it first Convolvulus Purga, and afterwards Ipomoea Purga. In 1832 it was described and figured by Zuccarini, under the name of Ipomoea Schiedeana.

Choisy, in De Candolle's Prodrumus (vol. ix. p. 374), has adopted Wenderoth's name of Ipomoea purga; but as the jalap plant has a salver-shaped (hypocrateriform) corolla and exerted stamens, it certainly cannot be an Ipomoea, a part of whose character is a campanulate corolla and included stamens.

**Sp. Char.**—Root tuberose; incassated, perennial. Stems annual, twining, branched, smooth. Leaves ovate, acuminate, cordate at the base, quite entire, and smooth on both sides. Peduncles 1- to 3-flowered. Sepals unequal, obtuse, smooth. Corolla salver-shaped, with a subcalvate, cylindrical tube, and a subpentagonal, horizontally-expanded limb.

Root perennial, irregularly ovate-conical, terminating inferiorly in some subcylindrical fibrous branches; covered by a very thin, dirty, blackish epidermis; internally white and fleshy. Stem herbaceous. Leaves alternate, petioled. Tube of the corolla purplish violet (red lake).

**Hab.**—In the woods of the Mexican empire, near Chiecanquiaco, at an elevation of nearly 6,000 feet above the level of the sea. Jalap is the only market for the root, from whence it is exported to Europe and the United States by way of Vera Cruz.

**Description.**—1. The dried tubers of true jalap (radix jalapae; rad. jalapae tuberosae vel ponderosae) found in commerce rarely exceed a pound each in weight. They vary in size, from that of the fist to that of a nut. When entire, they are usually more or less oval, and pointed at the two opposite extremities. The larger tubers are frequently incised, apparently to facilitate desiccation. They are covered with a thin, brown, wrinkled cuticle. They should be heavy, hard, and difficult to powder. When broken, good tubers should present a deep yellowish-gray colour, interspersed with deep brown concentric circles. The slices vary in their shape, colour, and other properties. Those of inferior quality, are light, whitish, friable; they usually appear to be quarter segments of transverse slices, and are sometimes called spurious jalap, or, from their shape, cocked-hat jalap. Jalap is very apt to become worm-eaten; but the insects which attack it devour the amylaceous matter and ligneous matter, and leave the resin. Hence worm-eaten jalap is well adapted for the preparation of extract.

2. A spurious jalap, called in Mexico male jalap, is sometimes found intermixed with the genuine sort. It was first described by Mr. D. B. Smith; and has been termed by Guiibourt light or fusiform jalap. It is the kind sometimes called in English commerce woody jalap or jalap wood, and which in Germany has been termed jalap stalks (stipites jalapae). It is the produce of Ipomoea Orizabensis, Ledanios. As met with in commerce, it is in slices or segments, which are more fibrous or woody than genuine jalap. The cut surface is often darker from exposure to the air, and uneven from the unequal shrinking in the drying process. Internally, the colour is whitish. The odour and taste are similar to, but feebler than, the true jalap.

---

1 American Journal of Medical Sciences for February, 1830.
3 Pharm. Central-Blatt für 1830, p. 458; and Lianna, viii. 615.
3. Guibourt has described a false rose-scented jalap. It is in tuberules which are not so dark-coloured as the genuine drug. They are deeply furrowed; the prominent parts of the furrows being white from the friction of the pieces against each other; the depressions being dark coloured. The pieces are but slightly resinous, are amylaceous and saccharine, and have rather an agreeable sweetish odour, which Guibourt compares to that of oil of rhodium or of the rose. It possesses scarcely any purgative action. It is probably the kind known in the American market as overgrown jalap.

Selection.—Jalap is more active as a cathartic in proportion to the quantity of resin which it contains; plump, firm, heavy, resinous pieces, therefore, are preferable. Light, whitish, amylaceous, shrivelled, or woody pieces are objectionable.

Composition.—Jalap was analyzed, in 1817, by Cadet de Gassicourt, and more recently by Gerber. Other less complete analyses have been made by Henry, by Ledanois, and by Nees v. Esenbeck and Marquart. In 1835, Cannobio analyzed a variety of jalap called guioppone, similar in appearance to galanga.

1. Jalap Resins.—The resinous portion of jalap is the most important, because it is the active ingredient of this root. The substance generally known as jalap resin is obtained by mixing the alcoholic extract of jalap (prepared by percolation or digestion) with water. The precipitated resin is to be washed with warm water, and then dissolved in alcohol. By evapora-

---

tion the tincture yields the resin. Planché⁴ has proposed another process. By digestion with animal charcoal the alcoholic solution of the resin is rendered nearly colourless, and by evaporation yields an almost colourless resin (resina jalape alba of Martius).⁵ Jalap resin is soluble in alcohol, but insoluble in water. Triturated with milk, it does not form an emulsion, but its particles unite into a solid mass. By this it may be distinguished from scammony resin.⁶ It is insoluble in the fixed and volatile oils. Its insolubility in oil of turpentine is a means of detecting the intermixture of some other resins, as of scammony and turpentine.⁷ Jalap resin is sometimes adulterated with guaiacum.⁸ This, unlike jalap resin (rhodeoretin) is soluble in ether; and paper moistened with its alcoholic solution is rendered blue by nitrous gas. Decolorized jalap is composed, according to Goebel,⁹ of carbon 36.02, hydrogen 9.47, and oxygen 53.91; but Johnston¹⁰ declares this analysis to be incorrect, and gives the following as the formula for the resin, C₉H₄NO₁₃.

According to Buchner and Herberger,⁸ as also Kayser,¹¹ the so-called jalap resin consists of two distinct resins, one soluble in ether, the other insoluble in this liquid.

a. Jalapin; Rhodoaretin (from jëlsse, rose-red, and jërusin, resin.) C₉H₄NO₁₃. Is this the jalapin of Mr. Hume?¹² This resin is insoluble in ether. Kayser obtained it by boiling purified jalap resin in ether, which took up the jalapic acid and left the jalapin. According to Buchner and Herberger it constitutes not quite nine-tenths of jalap resin. It is a transparent, colourless, odourless, and tasteless resin; very soluble in alcohol, but insoluble in water and in ether.

It does not possess basic properties, as Buchner and Herberger supposed; but, on the contrary, possesses acid properties, reddens litmus, and is soluble in ammonium and acetic acid. If the resin with which it forms with oxide of lead be decomposed by sulphurised hydrogen, the resin is then found to have combined with the elements of water and to have become converted into hydroxyrhodoaretin, C₉H₄NO₁₃.

b. Jalap acid; Odorous Principle of Jalap.?—Constitutes thirteen per cent. of jalap resin. It is a brown, soft, and greasy substance, which reacts as an acid, has the odour of jalap, and an acrid taste. By long contact with water it crystallizes. It is soluble in ether, in alcohol, and in alkaline solutions; but is insoluble in hydrochloric acid. It is either a crystallizable soft resin or a fatty acid.

Parahodoaretin; C₉H₄NO₁₃.—This is a simple resin, and is obtained from the male or fusi-form jalap (Ipomoea orizabensis.) It is soluble in both alcohol and ether.

If jalap resin (rhodeoretin or parahodoaretin) be digested in a watch-glass with oil of vitriol, a crimson coloured solution is obtained, from which in a few hours a brown viscous resin will separate. By this test jalap resin is distinguished from other resins.

2. Starch.—The starch grains vary in size. Their shapes are spheres, semispheres, or that of mullars. The hilum is very distinct.

Physiological Effects. a. On Animals generally.—Jalap root in powder, as well as the resin obtained from it, is a local irritant. Its operation on the bowels is well seen in the carnivora. Cadet de Gassicourt¹³ found that the resin applied to the pleura, peritoneum, or intestinal canal of dogs, caused fatal inflammation. Two draughts introduced into the stomach, the oesophagus being afterwards tied, killed a dog in a few hours. It is remarkable, however, that the same experimenter observed no particular effect from the application of a draught of the finely-powdered resin to the cellular tissue of the back. Moreover, 24 grains, with the yolk of an egg, injected into the jugular vein, had, he says, a very slight effect; indeed, at first none was observed, but the two following days the animal had soft, pale evacuations, and lost his appetite, though he soon recovered from this state. In the herbivora, it proves a very uncertain purgative. Gilbert¹⁴ gave two ounces to a sheep, without observing any effect. Donné¹⁵ administered two or three ounces to horses, without observing any remarkable effect, except increased secretion of urine.

b. On Man.—In the human subject jalap acts as a powerful and drastic purgative, producing copious liquid stools, and, when judiciously exhibited, is both safe and efficacious. Its objectionable effects are, that while in the stomach it causes

---

frequently nauseas, and sometimes vomiting; while, after it has passed into the intestines, it oftentimes gripes.

It is tolerably certain in its operation; more so, indeed, than many other purgatives. In the proper dose, it may be given without the least hesitation to children, in any case requiring an active purgative. It has an advantage over some other evacuants, that it does not stimulate or heat the system, its effect being confined, principally, to the alimentary canal—the peristaltic motion, secretions, and exhalations of which it promotes; and it is said that constipation less frequently succeeds its use than of some other purgatives.

My own experience of jalap would lead me to regard it as a perfectly safe, though active cathartic. But Dr. Christison\(^1\) says, that "severe and even dangerous effects have followed its incautious use in the hands of the practical joker." I am not acquainted with any cases, in the human subject, in which its employment has been attended by serious consequences. It is a more drastic purgative than senna. To scammony it is closely allied, not only by its effects, but also by botanical affinities and chemical properties. It is much less irritant to the intestinal mucous membrane than gamboge; and, therefore, is a much safer purgative. Vogt\(^2\) regards it as exceeding the last-mentioned substance, but as being inferior to aloes, in its stimulant influence over the abdominal and pelvic bloodvessels; and Sundelin\(^3\) observes that, while it is more irritant, it is less heating, than aloes or senna.

Uses.—Daily experience proves the value of jalap, as an active purgative, in various diseases both of children and adults. Of course, its irritant properties unfit it for exhibition in inflammatory affections of the alimentary canal, as well as after surgical operations about the abdomen and pelvis. Moreover, it is not an appropriate purgative in irritation of, or hemorrhage from, the uterus; or in piles and stricture, and prolapsus of the rectum. On the other hand, its use is indicated in torpid and overloaded conditions of the intestinal canal, as well as in constipation, attended with retention of the catamenia. When the object is to relieve cerebral congestion and dropsical affections, by a counter-irritant influence on the mucous membrane, jalap is well adapted to fulfill it, both by the energy and safety of its operation. The following are some of the cases in which it is employed:

1. In constipation.—When this condition is not dependent on, or connected with, irritation or inflammation of the alimentary canal or pelvic organs, jalap is admissible. Its efficiency is much increased by association with calomel. It may be employed in febrile and inflammatory diseases (those above mentioned excepted), as well as in chronic maladies.

2. As a verminifuge.—The compound of jalap and calomel is a most efficacious anthelmintic, and may be used with the most happy effects in children, especially where there is an excessive secretion of mucus. "Jalap," says Bremser,\(^4\) "is, without contradiction, in verminous diseases, one of the best purgatives, and which, perhaps, possesses, at the same time, greater anthelmintic virtues than any other."

3. In cerebral affections.—Jalap, in combination with calomel, is used with the best effect, on the principle of counter-irritation, to relieve cerebral congestion. In inflammatory affections of the brain or its membranes, or in hydrocephalus, it is a valuable purgative.

4. In dropsies.—In dropsical affections it is frequently desirable to promote watery stools. Jalap, especially in combination with cream of tartar, may be used for this purpose with the best effects. Margrave\(^5\) calls it a panacea hydroptericorum.

5. In retention of the catamenia, or of the hemorrhoidal flux, jalap is one of the purgatives adapted, from their stimulant influence over the pelvic vessels, to promote these discharges.

Administration.—The dose of jalap, in powder, is, for an adult, from ten to thirty grains; a scruple usually acts smartly and safely; for children under twelve

\(^{5}\) Traité sur les Verres Insect. p. 440.
months old the dose is from two to five grains. Fifteen grains of jalap and two or three grains of calomel, form an efficient, yet safe, purgative for an adult; but this combination very readily produces salivation by repetition. From two to five grains of ipecacuanha are sometimes substituted for the calomel. To children, jalap is sometimes exhibited in gingerbread cakes. Purgative cakes of this kind are kept in the shops. The Biscuits purgatifs (Panis saccharati purgantes) are composed of Jalap, 3xx; Flour 3ij; 24 Eggs; and Sugar lbj. This quantity is sufficient for 60 biscuits. ¹

1. PULVIS JALAP.Æ COMPOSITUS, L. E. D. [U. S.]; Compound Powder of Jalap.—(Jalap 2ijj [3ijj, D.]; Bitartrate of Potash 3vj [3ijss, D.]; Ginger 5ij [3ss, D.]. Rub them separately to powder; then mix them, L. The Edinburgh College uses the same proportions of jalap and bitartrate of potash as the London College, but omits the ginger.)—(This is also the case with the U. S. Pharm.)—Hydragogue purgative. Used in habitual costiveness, verminal diseases, and dropsies. Dose, for an adult, 3j to 3j.

2. TINCTURA JALAP.Æ, L. E. D. [U. S.]; Tincture of Jalap.—(Jalap, bruised, 3v [in moderately fine powder, 3vj, E.]; Proof Spirit Oij [Oiss, D.]. Macerate for seven [fourteen, D.] days, and strain, L. D. [The U. S. Pharm. directs Jalap, in powder; six ounces; Diluted Alcohol two pints. Macerate for fourteen days, express and filter through paper.] “This tincture may be prepared either by digestion or percolation, as directed for tincture of cinchona,” E.)—An active cathartic. Rarely used alone; generally employed as an adjunct to purgative draughts, the activity of which it promotes.—Dose, f3j to f3iv. As an adjuvant to a cathartic draught, the dose rarely exceeds f3j.

3. EXTRACTUM JALAP.Æ, L. [U. S.]; Extractum sive Resina Jalap.Æ, E.; Extract of Jalap.—(Jalap Root, powdered, Hbiiss. [Hbj, U. S.]; Rectified Spirit Cong. j [Oiv. U. S.]; Distilled Water Cong. ij [a sufficient quantity, U. S.]. Macerate the jalap root in the spirit for four days, and pour off the tincture. Boil down the residue in the water to half a gallon; afterwards strain the tincture and the decoction separately, and let the latter be evaporated, and the former distil, until each thickens. Lastly, mix the extract with the resin, and evaporate to a proper consistence, L. This extract should be kept soft, which may be fit to form pills, and hard, which may be rubbed to powder, L. The directions of the Edinburgh College are the following: “Take any convenient quantity of jalap, in moderately fine powder; mix it thoroughly with enough of the rectified spirit to moisten it well; put it in twelve hours into a percolator, and exhaust the powder with rectified spirit; distil off the greater part of the spirit, and concentrate the residuum over the vapour-bath to a due consistence.”—In this process, the alcohol extracts the resin, and the water subsequently used by the London College takes up the gummy extractive; the alcoholic tincture is distilled to save the spirit, while the aqueous decoction is evaporated. The preparation of the Edinburgh College is the impure resin of jalap; whereas, that of the London College is a mixture of resin with the gummy extractive. It was formerly, and indeed is now by many persons, supposed, that the combination of these ingredients was necessary for the full cathartic effect of jalap. It is, however, well known that the watery extract is inert as a purgative, though it is said to be diuretic; the only advantage, therefore, that can attend the mixture of the two extracts (the watery and the alcoholic), is, that the resin is intimately divided, and thereby prevented from causing violent irritation and gripping in any one part of the intestinal tube. But it is obvious that the same advantage can be obtained by mixing the resin with some mild agent (as almonds, sugar or saline matter, as sulphate of potash). Mr. Brande² says, that jalap yields about 66 per cent. of extract; that is, 16 of alkaloric, and 50 of watery extract. According to this statement, therefore, the extract of the Edinburgh Col-

¹ Jourdan, Pharmacopæe Universelle.
lege possesses four times the activity of that of the London College. The dose of the resin (Ph. Ed.) is from grs. iij to grs. vj, in a minute state of division, as above directed; of the extract, Ph. L., from grs. x to 3j.

183. Pharbitis Nil, Choisay.  
**Sex. Syst. Pentandria, Monogynia.**  
(Semina.)

*Convolulus Nil*, Linn.—A tropical plant, with purgative seeds. —The *Pharbitis Carules*, Wallich (*Ipomea carules*, König, in Roxb. Fl. Ind., vol. i. p. 501), is probably only a variety of it. Its seeds are sold in India under the name of *kala dana*, *hukul nil*, and *marchai*. They are black, angular, and weigh on an average half a grain each. Their taste is sweetish, and subsequently acid. They consist of resin, gum, starch, bland fixed oil, vegetable fibre, and colouring matter. They yield from 15 to 20 per cent. of alcoholic brown extract containing resin and oil. In doses of from 30 to 40 grains the seeds act as a quick and safe cathartic; in some few cases they occasion vomiting and griping. The alcoholic extract may be given in doses of ten grains. The effects of the seeds and extract resemble those of jalap, for which they may be substituted. Roxburgh directs the seeds to be gently roasted like coffee, then powdered, and given in any convenient vehicle.

**ORDER XLV. GENTIANACEÆ, Lindley.—GENTIANWORTS.**

*Gentianæ, Jussieu.*

**Characters.**—*Calyx* divided, inferior, persistent. *Corolla* monopetalous, hypogynous, usually regular and persistent; the limb regular, sometimes furnished with delicate fringes, its lobes of the same number as those of the calyx, generally 3, sometimes 4, 6, 8, or 10; occasionally, extended at the base into a bag or spur, with a plaited, or folded, or imbricated twisted revulsion. *Stamens* inserted upon the corolla; all in the same line, equal in number to the segments, and alternate with them; some of them occasionally abortive. *Ovary* composed of 2 carpels, 1- or partly 2-celled, many-seeded. *Style* 1, continuous with the ovary; *stigmas* 2, right and left of the axis; *ovules* indefinite, anatropal, parietal; *capsule* or *berry*, many-seeded; when two-valved, the margins of the valves turned inwards, and bearing the seeds; in the two-celled genera inserted into a central placenta. *Seeds* small; *testa* single; *embryo* minute in the axis of soft fleshy albumen; *radicle* next the hilum.—*Herbaceous* plants, seldom shrubs, generally smooth, sometimes twining. *Leaves* opposite, entire, without stipules, sessile, or having their petioles confluent in a little sheath, in most cases 3—5 ribbed; very rarely brown and scale-like; sometimes alternate. *Flowers* terminal or axillary, regular or very seldom irregular. (Lindley.)

**Properties.**—This order contains a bitter principle, which is especially abundant in the roots. On this substance depends the stomachic, tonic, and febrifuge properties of the different species.

184. GENTIANA LUTEA, Linn.—COMMON OR YELLOW GENTIAN.

**Sex. Syst. Pentandria, Digynia.**  
(Radix, L.—Root, E. D.)

**History.**—Gentian is said to owe its name and introduction into medical use to Gentius, king of Illyria, who was vanquished by the Romans about 160 or 169 years before Christ. It is, therefore, not noticed by either Hippocrates or Theophrastus, but is mentioned by Dioscorides, who calls it *gentiana*; and by Pliny.¹

**Botany.** —*Gen. Char.*—*Calyx* 5—4-parted or split, sometimes dimidiate-spathaceous, valvate. *Corolla* withering, rarely glandular, without epipetalous hollows; the limb 5—4-parted, or spuriously 10-parted. *Stamens* 5—1, inserted in the tube of the corolla; filaments equal at the base. *Ovary* 1-celled; the ovules in rows next the suture. *Stigmas* 2, terminal, revolute, or, if contiguous, funnel-shaped; *style* 0, or persistent with the stigmas. *Capsule* 2-valved, septicidal, 1-celled: the placenta membranous. *Seeds* immersed in the placenta. (Condensed from Grisebach.)

¹ O'Shonginessey, Bengal Dispensatory.  
² Hist. Nat. lib. xxv. cap. 34, ed. Valp.
Sp. Char.—Stem tall, straight. Leaves oval and ovate, smooth at the margin. Cymes umbelliform, dense-flowered, axillary or terminal, pedunculate. Corollas yellow; the segments oblong-linear, acuminate (Grisebach).

Root perennial, cylindrical or spindle-shaped, simple or somewhat branched, ringed, wrinkled, externally brown, internally yellow and fleshy. Stem simple, erect, 2—3 feet high, roundish, hollow, smooth. Leaves, pale green, opposite, ovate or oval, pointed, entire, smooth, 5—7-ribbed, plaited; lower ones on short, sheathing petioles; upper ones amplexicaul; those next the flowers becoming concave yellowish-green bracts. Flowers on smooth peduncles of 4—6 lines long. Calyx yellow; Corolla yellow; segments 5—7, lanceolate. Stamens as long as the corolla. Ovary conical, with 5 greenish glands at the base. Capsule conical, 2-valved. Seeds numerous, roundish, albuminous, with membranous margins.

Hab.—Subalpine and mountainous meadow, 6500—8000 feet above the level of the sea, of Central and Southern Europe.

Collection.—The roots are collected and dried by the peasants of Switzerland, the Tyrol, Burgogne, and Auvergne. They are imported into this country in bales from Havre, Marseilles, &c.

Description.—Gentian root (radix gentianae) is imported in cylindrical, usually more or less branched pieces, varying in length from a few inches to a foot or more, and in thickness from half an inch to one or two inches. These pieces are marked by transverse annular wrinkles and longitudinal furrows. Externally the root is yellowish-brown, internally it is brownish-yellow; its texture is spongy; its odour, in the fresh state, peculiar and disagreeable; its taste is intensely bitter. The root of other species of Gentiana are said to be frequently mixed with those of the official species; their effects, however, are analogous.

Martius says, that the roots of G. Purpurea have strong longitudinal furrows, and are of a darker brown colour internally, but want the transverse wrinkles. The roots of G. pannonica are similar to those of purpurea. Both kinds are met with in Bavaria, and are collected in Switzerland for the preparation of a spirit. Gentiana punctata has roots which are just as bitter, but of a more yellow colour; they are dug up in great abundance in Moravia. The roots of both the last-mentioned species are dug up at, and exported from, Salzburg; in the fresh state they are white when sliced.

Chemistry.—Gentian root was analyzed, in 1815, by Schrader, in 1817 by Braeconnor, in 1818 by Henry, in the same year by Guillemin and Fœqueumin, and in 1821 by Henry and Caventou. In 1857 it was examined by Leconte. The constituents of gentian root, according to Henry and Caventou, are—a volatile odorous matter, bitter crystalline matter (gentianin), fuyacous odorous principle (volatile oil?), yellow colouring matter, green fixed oil, gum, uncrystallizable sugar, matter identical with bird-lime, a free organic acid, and woody fibre. But in 1837, H. Trommsdorff and Leconte showed that, under the name of gentianin, two substances had been confounded—the one crystalline and tasteless; the other bitter. The first has been called gentisin; the second gentianinit. Furthermore, Leconte has shown that the substance considered by Henry and Caventou as identical with bird-lime, is a compound of wax oil and caoutchouc.

1. Oil of Gentian.—By distillation with water, gentian root yields a very small quantity of a butyrycous oil, which floats on water, has a powerful odour of gentian root, and is soluble in alcohol. A few drops of the melted oil were given to a rabbit, without causing any remarkable effects. I have received from Mr. Whipple two samples of this oil, the one green, the other white like mutton fat. Three eet. of the root yielded only about 3.5. of oil.

Planché states, the distilled water of gentian caused nausea and a kind of intoxication.

2. Gentisin, or Gentisic Acid.—Procured by washing the alcoholic extract of the root

1 Pharmacognosie.

7 Journ. de Pharm. t. v. p. 97.
8 Ibid. t. vii. p. 173.
with water, and then treating with alcohol. The tincture obtained was evaporated, the extract treated by ether; the residue, by successive solutions and evaporations, yielded gentisin. It is pale yellow, crystallizable in needles, has a peculiar but weak smell. When cautiously heated, it gives out some yellow vapours, which are condensed on the upper part of the tube. It is scarcely soluble in water, but dissolves in alcohol. With alkalies, it unites to form salts. Its saturating power is about 438. Trommsdorff says, that a solution of gentisic acid is unaffected by acetone of lead, nitrate of silver, and most other tests. Chloride of iron and the salts of copper produced, in the alcoholic solution, the most characteristic changes.

3. Bitter Principle of Gentian (Gentianate)—This has not hitherto been isolated. By digesting the alcoholic extract of gentian in water, an acridious intensely bitter solution is obtained. The acid may be thrown down by lead. When the excess of lead has been removed from the solution by sulphuretted hydrogen, a liquid is obtained, which, by evaporation, yields a sweet and very bitter extract, from which ether removes an aromatic fat, an odorous resin, and wax. The bitter matter has not been separated from the sugar.

4. Pectin.—The existence of pectic acid (pectin) in gentian, was ascertained, in 1835, by Denis.1 To this substance is to be in part, perhaps, ascribed the gelatinization of infusion of gentian, which, under certain circumstances, is not unfrequently observed. 

5. Sugar.—To the presence of this matter in gentian is to be ascribed the capability of the infusion of gentian to undergo the vinous fermentation, and to form an alcoholic liquor (gentian spirit), much admired by the Swiss.2

Chemical Characteristics.—The infusion of gentian is deepened in colour by the caustic alkalies. Sesquichloride of iron communicates a deep olive-brown tint. The acetate and diacetate of lead, the sulphate of copper, and the nitrate of mercury, cause flocculent or gelatinous precipitates (metallic pectates?).

Physiological Effects.—Gentian is very properly regarded as a pure or simple bitter; that is, as being bitter, but without possessing either astringency or much aroma. It has, therefore, the usual tonic properties of medicines of this class, which I have before noticed (see vol. i. p. 244).

Given in full doses, it appears more disposed to relax the bowels than the other simple bitters, and, in susceptible individuals, it is more apt to disorder the digestive process. In such cases, both Loseke and Voigtet3 have seen it cause vomiting. Barbier4 says it quickens the pulse. It is somewhat less bitter, and therefore, I presume, somewhat less powerful, than quassia.

By continued use, the sweat and urine acquire a bitter taste;5 a sufficient proof that gentian, or its bitter principle, becomes absorbed.

As some of the vegetable bitter tonics (for example, quassia and calumba) have been found to exert a specific influence over the cerebro-spinal system, and to yield preparations of a poisonous quality, we are naturally led to inquire whether any analogous facts have been made out with respect to gentian. The reply is in the affirmative. Magendie,6 indeed, discovered no poisonous operation in Gentianin; he threw several grains of this principle into the veins of an animal, without any obvious effect, and swallowed two grains, dissolved in alcohol, but only observed extreme bitterness, and a slight feeling of heat in the stomach. Moreover, Harl7 inserted two grains of the extract of gentian into the inner side of the thigh of a rabbit, without any ill effects resulting; the wound was slightly inflamed, though it soon healed. These facts prove, that the bitter extractive of gentian possesses no narcotic properties. But if the narcotic principle of gentian be of a volatile nature, these experiments of Magendie and Harl go for nothing, since, in the preparation of both the extract and the gentianin, this principle would be dissipated by the heat employed. Now, Planche8 has shown, as I have already mentioned, that the distilled water of gentian causes violent nausea, and, within three minutes, a kind of intoxication. Moreover, Buchner9 tells us that, some years ago, a narcotic effect was produced in Prussia, by the medicinal use of gentian root, although the presence of any foreign matter could not be detected. In the Philosophical Transac-

1 Journ. de Pharm. t. xxii. p. 303.
4 Arnechim. Pfant. Arnechimittl. S. 166, 6te Aufl.
5 Formal. p. 313, 5me edit.
7 Ibid.
9 Toxikol. S. 192.
tions for the year 1748, are mentioned some deleterious effects, resulting from the use of gentian; but they were referred to a foreign root, said to have been inter-
mixed with, and which greatly resembled, the true gentian root.

All these facts, then, support the opinion of Haller (quoted by Buchner), that
gentian is not so innocuous as is generally supposed.

Uses.—Gentian is adapted to most of the cases requiring the use of the pure or
simple bitters (see vol. i. p. 244). It agrees best with phlegmatic, torpid individu-
als, and is apt to disagree with irritable or susceptible persons. It is contraindi-
cated in febrile disorders and inflammatory conditions of the gastro-intestinal mem-
brane. It is employed principally in the following cases:—

1. **In dyspepsia, and other gastric disorders,** attended with debility or torpidity,
and unaccompanied by any marks of inflammation or irritation, or great suscepti-
bility, of the digestive organs. Sesquicarbonate of ammonia is a very valuable adjunct.

2. **In intermittent diseases** it may be used where cinchona is admissible; but it
is much inferior to the last-mentioned substance. "Joined with galls or tormentil,
in equal parts, and given in sufficient quantity, it has not failed," says Dr. Cullen,¹
"in any intermittents in which I have tried it."

3. In many other diseases marked by weakness and debility, but unattended by
fever or gastro-intestinal irritation, gentian is admissible and useful; as in some
forms of gout, hysteria, uterine disorders, &c. It is a constituent of the Duke
of Portland’s powder for the gout (see ante, p. 387).

4. **Against worms,** it has been used as if it possessed some specific influence.

5. In surgery, it has been used for discutient fomentations, also in the form of
fine powder, as an application to issues, to promote their running, and as a tent, to
enlarge and cleanse fistulous apertures.²

Administration.—In the form of *powder,* the dose is from grs. x to 5ss. But
the infusion, tincture, or extract, are the usual forms of exhibition.

1. **Infusum Gentianae Compositum,** L. D. [U. S.]; *Infusum Gentianae,* E.; *Infu-
son of Gentian; [Compound Infusion of Gentian, U. S.].—(Gentian Root, sliced,
3ij; Orange Peel, dried, 3ij [Lemon Peel, fresh, 3iv, L.]; Boiling [Distilled,
L.]. Water Oj [Oss, D.]; Macerate for an hour in a vessel lightly covered, and
strain. The directions of the Edinburgh College are as follows: Gentian, sliced,
3ss; Bitter Orange Peel, dried and bruised, 3j; Coriander, bruised, 3j; Proof
Spirit f3iv; Cold Water f3xvj [f3xij, U. S.].—Pour the spirit upon the solids;
in three hours add the water, and in twelve hours more strain through linen or
calico.)—The infusion of the London and Dublin Pharmacopoeias is very apt to
spoil by keeping; but as it can always be speedily procured, this is not a circum-
stance of much importance. However, to obviate it as much as possible, the
Edinburgh College orders cold water to be used (by which less of the mucilaginous
matter [pectin, &c.] is dissolved), and employs spirit to promote the solution of
the bitter principle, while the quantity of gentian is much increased; so that, in fact,
we have a weak tincture, rather than an infusion. Besides the objections which
may arise out of these deviations, a very important one is the length of time re-
quired for the maceration.

Compound infusion of gentian sometimes gelatinizes by keeping. This occurred
in one case when the infusion instead of being strained off in an hour had been
allowed to stand forty-eight hours, and liquor potassæ had been added to it. Though
this perhaps may be in part due to the action of the alkali on the pectin contained
in the gentian, it is chiefly, if not entirely, owing to the action of the alkali on
some principle extracted by prolonged maceration from the lemon-peel (see *cortex
limonum*).

Infusion of gentian is stomachic and tonic. When prepared according to the
London and Dublin Pharmacopoeias, the dose is f3j to f3ij; when according to that
of the Edinburgh, f3ss to f3j.

⁴ Ibid. vol. i. p. 237, 1841.
2. MISTURA GENTIANAE COMPOSITA, L.; Compound Mixture of Gentian.—(Compound infusion of Gentian \(\frac{1}{2}\)\(\text{x}j\); Compound Infusion of Senna \(\frac{3}{2}\)\(\text{vij}\); Compound Tincture of Cardamoms \(\frac{1}{2}\)\(\text{ij}\). Mix.—Tonic and cathartic. Used in dyspepsia with constipation.—Dose, \(f_{\text{ij}}\) to \(f_{\text{ij}}\).

3. TINCTURA GENTIANAE COMPOSITA, L. E. D. [U. S.]; Tincture of Gentian.—(Gentian, sliced and bruised, \(\frac{3}{2}\)\(\text{iss}\) [\(\frac{3}{2}\)\(\text{ij}\), D.]; Orange Peel, dried, \(\frac{5}{x}\) [\(\frac{3}{2}\)\(\text{iss}\), D.]; Cardamom [seeds], bruised, \(\frac{5}{y}\) [\(\frac{3}{2}\)\(\text{is}\), D.]; Proof Spirit Oij. Macerate for seven [fourteen, D.] days, express and strain, L. D. The Edinburgh College employs of Gentian, sliced and bruised, \(\frac{5}{x}\)\(\text{iss}\); Dried Bitter Orange Peel, bruised, \(\frac{5}{x}\); Canella, in moderately fine powder, \(\frac{3}{y}\); Cochineal, bruised, \(\frac{5}{x}\); and Proof Spirit, Oij. [The U. S. Pharm. directs Gentian, bruised, \(\frac{3}{j}\); Orange Peel \(\frac{3}{j}\); Cardamom, bruised, \(\frac{5}{x}\); Diluted Alcohol Oij. Macerate for fourteen days, express, and filter through paper; or it may be prepared by displacement.] This tincture may be more conveniently prepared by percolation, as directed for the compound tincture of cardamom, E.])—A grateful cordial tonic and stomachic. Employed as an adjunct to the infusion, effervescing draughts, bottle soda-water, &c.—Dose, \(f_{\text{ij}}\) to \(f_{\text{ij}}\).

4. VINUM GENTIANAE, E.; Wine of Gentian.—(Gentian, in coarse powder, \(\frac{5}{x}\); Yellow Bark, in coarse powder, \(\frac{3}{j}\); Bitter Orange Peel, dried and sliced, \(\frac{5}{x}\); Canella, in coarse powder, \(\frac{3}{j}\); Proof Spirit \(f_{\text{ivs}}\); Sherry Oij and \(f_{\text{ix}}\). Digest the root and barks for twenty-four hours in the spirit; add the wine, and digest for seven days more; strain and express the residuum strongly, and filter the liquors.)—Wine of gentian is an aromatic tonic, useful in dyspepsia and anorexia. It is apt to become acetoys by keeping.—The dose of it is \(f_{\text{ij}}\) to \(f_{\text{ij}}\).

5. EXTRACTUM GENTIANAE, L. E. D. [U. S.]; Extract of Gentian.—(Gentian, sliced, \(\frac{3}{x}\); Boiling Distilled Water Oij. Macerate for twelve hours in four pints of the water; pour off the liquor and strain it. Add two pints of the water to the residue, macerate for six hours, lightly express the liquor and strain. Lastly, evaporate the mixed liquors to a proper consistence, L. "Take of Gentian, any convenient quantity; bruise it to a moderately fine powder; mix it thoroughly with half its weight of distilled water; in twelve hours put it into a proper percolator, and exhaust it by percolation with temperate distilled water; concentrate the liquid, filter before it becomes too thick, and evaporate in the water-bath to a due consistence," E. Gentian Root, in thin slices, \(\frac{3}{j}\); Distilled Water Oij. Macerate the gentian in one pint and a half of the water for six hours, then strain and express. Add to the residue the remaining pint and a half of water, macerate again for six hours, strain, and express. Finally, mix the liquors, and evaporate by a steam or water-bath to a proper consistence, D.—[Gentian, in coarse powder, \(\frac{3}{j}\); Water, a sufficient quantity. Mix with a pint of water; allow to stand for twenty-four hours; and then displace until the bitterness of the gentian is exhausted. Evaporate to the proper consistence, U. S.]—Good gentian root yields, by the process of the London Pharmacopoeia, about half its weight of extract. Extract of Gentian is tonic. It is usually employed as a vehicle for the exhibition of the metallic substances (especially chalybeates) in the form of pill.—Dose, grs. x to \(f_{\text{ox}}\).

185. OPHELIA CHIRATA, Grisebach.—THE CHIRETTA OR CHIRAYTA.

History.—This plant seems to have been long in use among the natives of India. Professor Guibourc thinks that it is the \(\chi_{\text{alamos}}\) \(\text{dromatios}\) of Dioscorides.*

---

4 Lib. i. cap. 17.
(see ante, p. 154). Various circumstances, however, appear to me to be opposed to this opinion; one of the most conclusive is the absence of odour in the chirayta plant.  

**Botany.**  

**Gen. Char.** —Calyx 5—4-parted; the segments valvate. Corolla withering, rotate, 5—4-parted, with glandular pits above the base. Stamens 5—4, inserted in the throat of the corolla; the filaments either dilated at the base and monadelphous, or equal at the base and free. Ovary 1-celled; ovules numerous, inserted on the suture. Stigmas 2, terminal, short, usually revolute; style 0, or short. Capsule 2-valved, septicidal, 1-celled; placenta either spongy and sutured, or expanded near the suture. Seeds immersed in the placenta, very numerous, small, and generally wingless (Grisebach).  

**Sp. Char.** —Stem terete, tall, smooth, branched. Branches elongated, erect—spreading. Leaves cordate-ovate, and ovate, acuminate, sessile, smooth, 5—7—nerved. Cymes umbelliform, lax, few-flowered. Segments of the calyx sublan-ցate, acuminate, shorter than the corolla, corolla 4—parted, yellow, the segments expanded, ovate-lanceolate, acuminate; pits in pairs, oblong, distinct, fringed anteriorly by long scales; the fringes epipetalous, short, connecting the pits. (Grisebach.)  

**Herbaceous.** Root branching. Stem round, jointed. Leaves opposite amplexicaul, very acute, entire. Flowers numerous, peduncled.  

**Hab.** —Mountains of Nepal and the Morungs.  

**Description.** —The plant is pulled up by the root, about the time that the flowers begin to decay and the capsules are well formed. The dried plant, with the root (herba et radix chirettse sive chiraytse) is met with in the shops. The root is fibrous; the stem is round, smooth, not jointed, marked with the cicatrices of leaves, has a yellowish pith; the leaves are as above described. The whole plant is without odour, but has an intensely bitter taste.  

**Composition.** —The stems of this plant were analyzed by MM. Lassaigne and Boissel, who obtained the following results: resin, yellow bitter matter, brown colouring matter, gum, malic acid [woody fibre], malate of potash, chloride of potassium, sulphate of potash, phosphate of lime, silica, and traces of oxide of iron.  

The bitter matter is the most important constituent. No vegetable alkali has been detected in it. The substance which was sold as sulphate of Chiraytine was sulphate of quinina.  

**Physiological Effects.** —Chirayta is an intensely bitter substance, and produces the before-described (see vol. i. p. 244) effects of the simple or pure bitters. In its operation, as well as by its botanical affinities, it is closely allied to gentian. It appears to possess rather a relaxing than a constipating effect.  

**Uses.** —It has long been employed by the natives of India in the same class of cases in which gentian has been used in Europe. As a stomachic it is especially serviceable in the dyspepsia of gouty subjects. It strengthens the stomach, obviates flatulency, and diminishes the tendency to acidity. Combined with the seeds of Guilandina Bonduc it is employed with success in intermittents.  

**Administration.** —It may be given in powder, in the dose of 3j, or it may be employed in the form of infusion, tincture (prepared with cardamon and orange peel, like compound tincture of gentian), or extract.  

1. **Infusum Chirettse, E. D.; Infusion of Chiretta.** —(Chiretta 3iv [3j, D.]; Boiling Water Oj [3ixs, D.]. Infuse for two hours, and strain through linen or calico). The dose of this is 3j to f3j.  

2. **Tinctura Chirettse, D.; Tincture of Chiretta.** —(Chiretta, bruised, 3v; Proof Spirit Oj. Macerate for fourteen days, strain, express, and filter, D.) —Dose, 3j to 3iv.
186. Erythrea Centaurium, Person.—Common Centaury.

**Sex. Syst. Pentandria, Monogyonia.**
(Centaurnium, L.—The flowering heads, E.—Folia, D.)

**History.**—This plant was known to the ancients, and received one of its names (Chrosia Centaurium) from Chiron the Centaur, who is said to have lived 1270 years before Christ. But the plant which, Pliny¹ says, cured Chiron of a wound received by an arrow, which he dropped on his foot when examining the arms of Heracles, is supposed to be the Centaurium Centaurium.  

**Botany. Gen. Char.**—Calyx, 5—4-partite, the segments nearly flat, wingless. Corolla funnel-shaped, naked, contorted-withering above the capsule; the tube cylindrical; the limb 5—4-partite. Stamens 5—4, inserted above in the tube of the corolla; anthers erect, twisted spirally, exserted. Ovary 1-celled or semi-2-celled in consequence of the valves being slightly inflexed. The ovules inserted at the suture. Style distinct, deciduous; stigma bilamellate or undivided and capitulate. Capsule bivalved, septicidal, 1-celled or semi-2-celled; the placenta spongy and sutured. Seeds immersed in the placenta, sub-globose, smooth, minute (Grisebach).

**Sp. Char.**—Stem erect, elongated, branched superiorly. Leaves elliptic-oblong, unequally acute. Flowers collected in loose heads, lateral, libractate. Tube of the corolla during inflorescence more than twice the length of the calyx, the tubes oval and obsolete. Capsule with the valves much inflexed, more than semi-2-celled (Grisebach).

**Root.** Small, tapering. Stem about a foot high, leafy. Radicle leaves obturate; the rest acute, ovate, or elliptic-lanceolate; 3-striated, bright green. Flowers nearly sessile. Bracts opposite, awl-shaped. Calyx slender. Tube of corolla pale-greenish; limb brilliant pink, expanded only in sunshine, closing as soon as gathered.

**Hab.**— Indigenous; dry gravelly pastures. Annual: Flowers in July and August.

**Description.**—The herb or tops (herba seu summitates vel cacumina centaurii minoris) of the common or lesser centaury are without odour, but have a very bitter taste. They are collected when in flower.

**Composition.**—According to Moretti,² common centaury contains bitter extractive, free acid, mucous matter, extractive salts [and woody fibre].

The principal constituent of common centaury is the bitter extractive, called by Dulong d’Astaforte centaurin. This, when combined with hydrochloric acid, is said to be an excellent febrifuge. Centaurn must not be confounded with centaurite, the bitter principle of Cnicus benedectus, De Cand.

**Physiological Effects.**—Similar to those of gentian (see ante, p. 525), and of other simple or pure bitters (see ante, p. 244).

**Uses.**—Common or lesser centaury is rarely used by medical practitioners; yet it might be employed as an indigenous substitute for gentian. Dose of the powder, ⁵ ³ to ⁵ ². It may also be used in infusion.

187. Menyanthes trifoliata, Linn.—Common Buckbean; Marsh Trefoil.

**Sex. Syst. Pentandria, Monogyonia.**
(Menyanthes, L.—Leaves, E.—Folia, D.)

**History.**—Sprengel¹ considers this to be the plant referred to by Theophrastus² under the name of ménain.  

**Botany. Gen. Char.**—Calyx 5-partite, the segments connected at the base, so as to form a tube. Corolla deciduous, funnel-shaped, fleshy; the limb, 5-partite, its segments naked at the margin and base, but fringed or very rarely denuded at the disk, no epipetalous glands. Stamens 5, inserted in the tube of the corolla; filaments equal at the base; anthers erect. Ovary surrounded by 5 hypogynous glands, 1-celled; the ovules inserted on the axis of the valves. Style filiform, persistent with the 2 lobed stigma. Capsule 1-celled, almost valveless, rupturing near the suture of the two carpels; the placenta inserted in the axis of the carpella. Seeds indefinite, with a shining very smooth testa. (Grisebach.)

**Sp. Char.**—The only species.  

**Hab.**—Indigenous; watery meadows, ditches, &c.; frequently cultivated in ornamental aquaria, on account of the beauty of the flowers of the flowers. Perennial. Flowers in June and July.

VEGETABLES.—Nat. Ord. Loganiaceae.

Description.—The whole herb (herba menyanthis seu trifoliis florinii) is odourless, but has a very bitter taste. Its infusion strikes a green colour (tannate of iron) with the sesquichloride of iron. The leaves (folia menyanthis) are the parts usually employed.
